The committee for procuring assistance for medical men and their families who may suffer from the war consisting of members elected by delegates from all medical societies in Russia has decided to organise an all Russia fund admitting however a certain local autonomy to the various cooperating funds The *Novosti* says that a central elected bureau is to be formed and regular monthly subscriptions are to be solicited which will not exclude independent gifts; thus the Society of Russian Physicians has subscribed £50 and other similar contributions have been received.

The gold medal founded by the late Sir Gilbert Blane, Bart., to be given biennially has been awarded by the Director-General of the Royal Navy Medical Service and the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England, to Staff Surgeon S. T. Reid, R.N., for his journal of H.M.S. *Vestal* for 1901-02 and to Surgeon R. W. G. Stewart, R.N., for his journals of H.M. ships *Latona* and *Thames* for 1903.

Correspondence.

"Audi alteram partem."

MEDICAL TEACHING IN THE METROPOLIS.

To the Editors of THE LANCET.

SIRS,—As senior physician to one of our teaching hospitals in London I feel compelled to say something in answer to the letter of Dr. Harry Campbell in THE LANCET of Feb. 18th on medical teaching in the metropolis. He says that it cannot be said that clinical medicine is well taught in London and that few of our London physicians are experts in the art of imparting the knowledge and skill which he allows they possess. He states that this is mainly owing to the fact that in the election of physicians to teaching hospitals due regard is not had to their teaching capabilities and his remedy is that all who are subsequently found incapable should be dismissed and, further, that certain gentlemen attached to hospitals unconnected with schools should be appointed to assist. This charge of incompetence, which is brought against the large number of 91 physicians and assistant physicians connected with the 12 teaching hospitals, besides medical tutors and registrars, is unsupported by a single statement of fact. He says *few* are capable of teaching. What is Dr. Campbell's definition of few? Is it 10, or 20, or 30 per cent.? Does Dr. Campbell's knowledge of London clinical teaching justify him in saying that 70 per cent., or even one-half of these gentlemen—and these would amount to 50—are incapable of teaching?

Now I am not concerned at present to do more than defend the hospital with which I am connected from its share of this charge. I have no doubt that other teaching hospitals will have an answer ready. But I am quite sure that as long as I have been connected with Guy's Hospital it is few of the physicians who have *not* been good teachers and that the clinical teaching has been, and is, carried out earnestly, thoroughly, and effectively, day after day by all concerned. With regard to the alleged cause I think I can safely say that no assistant physician during the last 40 years has been elected to the staff of Guy's Hospital who has not had experience in teaching and whose capacity to teach has not been taken into consideration as a factor in his election. The experience in teaching has been generally acquired in some probationary appointment requiring re-appointment every one or two years, such as that of demonstrator or registrar. Dr. Campbell's suggestion that we might pick up some worthy persons from the non-teaching hospitals presents this difficulty: How are we to know that they can teach? I am, Sirs, yours faithfully,

Wimpole-street, W., Feb. 18th, 1905. FREDERICK TAYLOR.

To the Editors of THE LANCET.

SIRS,—Obvious perils beset the path of any writer who attempts to argue from the known to the unknown or who ventures to generalise upon the assumption that his major premiss will meet with universal acceptance; these perils and this assumption are to be found in painful prominence in the letter under the above heading which appeared in THE LANCET of Feb. 18th, p. 458, in which the writer assumes that all will agree that clinical surgery is well taught in the London schools but that the like cannot be said of clinical medicine. He proceeds to deplore the assumed dearth of good clinical teachers of medicine as though all were equally agreed about that point. As one of the clinical teachers of medicine recognised by the University of London I feel that a protest should be made against the sweeping assertions of the writer of the letter. It is possible that he may be mistaken both as to the general agreement of the excellence of surgical teaching and as to the weakness of that of clinical medicine. He surely cannot pretend to be personally acquainted with the teaching of every school. He can only speak with a semblance of authority of the teaching of his own school, and it may be well to leave that school to deal with his criticisms. On the other hand, I venture to think that the suggested superiority of surgical teaching might be submitted to a truer test than that of average attendances—viz., the test of results. The records of the examinations of the Conjoint Board show that a larger percentage of men are rejected in surgery than in medicine, in spite of the suggested excellence of the teaching of surgery and the greater average attendance of students in the surgical wards. That it is more difficult to impart a knowledge of medicine is self-evident since students have to be taught to observe, and though it may be easy to tell them what should be heard with their stethoscopes they must take personal trouble to educate their special senses.

That there are "not a few capable men in London connected with non-teaching hospitals" it would not be wise to question, but surely they have at one time had their opportunity of being chosen to fill vacancies in the ranks. Having been passed over when their merits and their teaching powers were freshly within the recollection of the electing body of their own school it is scarcely to be expected that they should be called back to supersede those who have been continuously engaged in promoting the interests of the medical school. I am, Sirs, yours faithfully,

Harley-street, W., Feb. 20th, 1905. NESTOR TIRARD.

To the Editors of THE LANCET.

SIRS,—The letter from Dr. Harry Campbell in your last issue deplores the system of election at the medical schools and its suggested influence upon the teaching of medicine. The writer states, and we must take his word for the accuracy of the statement, that "there are not a few capable men in London connected with non-teaching hospitals." The adaptation of sundry remarks by the immortal Captain Cuttle and his friend Jack Bunsby may be of service. "A man's thoughts is like the winds, and nobody can't answer for 'em for certain, any length of time together." "Overhaul the ... (Medical Directory) and when found make a note of." "For why? Which way? If so, why not? Therefore." "The bearings of this observation lays in the application on it."

I am, Sirs, yours faithfully,

Feb. 18th, 1905. A STUDENT OF "BOZ."

To the Editors of THE LANCET.

SIRS,—I have read with much interest Dr. Harry Campbell's letter upon this subject and as it is one of wide-reaching public and professional interest I venture to make a remark upon it and to put forward a practicable suggestion. It is hardly possible to get all the governors of the London teaching hospitals into one way of thinking as to the methods of selecting their physicians and surgeons nor, perhaps, would the staff agree to losing a comrade through his failure to come up to Dr. Campbell's test. Medical teaching might be very much improved, not only in London but elsewhere, if it became compulsory to spend the last two years of the five years' curriculum in centres where there are large numbers of teachers to choose from and if one uniform fee allowed a student to attend any teacher he chose. Suppose all the teachers in London formed themselves into a body and freely admitted anyone possessing such qualifications as are now required for teachers and for clinical teaching all who had a requisite number of beds or out-patients from which to teach. An annual fee of £25 or £30 might be charged to each student and distributed *pro rata* to each teacher, school, or hospital, according to the numbers attending. This would enable men to attend several hospitals at one time, to choose their teachers, and not be compelled as they are at present (on account of the composition fee) to attend such teachers as the hospital board appoints to teach them.

It must be granted that some hospitals and schools have advantages over others and doubtless every one of them has some special advantage which a student may reap, but can it be said that every hospital and school are perfect in every particular? Whatever defect in the teaching there is it is reflected upon the student, and though he may be unusually well armed at one part his armour has serious weaknesses. Such a scheme would relieve the strain of maintaining a staff for the primary and scientific work and allow the universities and university colleges to fulfil their proper duties to the profession. Dublin, Glasgow, and Edinburgh might be similar centres and work upon similar lines. This project I respectfully submit is feasible, cannot injure anyone, and only requires the support of the General Medical Council to effect the reform. Your space is too valuable to dilate upon other obvious advantages.—I am, Sirs, yours faithfully,

Feb. 18th, 1905. R. C. H.

EFFECTS OF ANÆSTHETICS UPON PLANTS.

To the Editors of THE LANCET.

SIRS,—Besides the effect upon the sensibility of "mimosa pudica" noticed by your correspondent Dr. R. Macdonald and the enhancing of rest to which you refer several other effects of anæsthetics upon vegetable life have now been observed. It may interest Dr. Macdonald to be referred to some of these. The streaming of protoplasm, cell division, and cellular respiration are all affected in the direction of paralysis by solutions or vapours of ether and of chloroform. Elfving and Lauren[1] state that respiration in the higher plants is increased by ether and by chloroform but this is denied by other authorities. Claude Bernard showed that fermentation can be inhibited by chloroform. Again photosynthesis (the manufacture of sugar and starch from CO_2 and H_2O in chlorophyll-containing cells) is stopped by placing plants in an atmosphere which contains quantities of ether not enough to stop respiration. It would seem indeed, generally speaking, that vegetable life is as susceptible as animal life to the peculiar action of anæsthetic drugs but these are not so easily brought to bear upon the vegetable tissues as in the case of animals.

I am, Sirs, yours faithfully,

eb. 20th, 1905. J. BLUMFELD.

THE TREATMENT OF FRACTURES BY EARLY STRAPPING, EARLY MASSAGE, AND EARLY MOVEMENT.

To the Editors of THE LANCET.

SIRS,—Having for the last 20 years treated sprains, fractures, and dislocations upon the system described by Mr. J. Stafford Mellish in THE LANCET of Feb. 11th, p. 350, and having applied such treatment to my own fractured leg some years ago, I am in a position to write with considerable personal knowledge of the results. My own case of Pott's fracture of the leg I brought before the Medical Society of London and it was reported in the *British Medical Journal* of Feb. 15th, 1896. It was also referred to in an article in THE LANCET on Feb. 5th, 1898. A few of my personal experiences may be of interest now. My surgical friends were at first very much opposed to my using plaster strapping, but having applied it myself within half an hour of the accident it entirely prevented swelling of the injured part and gave me great comfort

Throughout the treatment I realised all the advantages which have been claimed for this system and I began to walk 21 days after the accident. It is always advisable to shave and to cleanse carefully the injured limb before applying the plaster. The plaster should be cut in strips from one to two inches wide, long enough to surround the limb and [illegible] It should be just laid on [illegible] o produce pressure. The [illegible] does not require artificial [illegible] rubber plasters are apt to irritate the skin. Oxide of zinc plasters suit some skins but the best kind is one called Eccles' plaster. Gentle massage cannot be commenced too early and Mr. Mellish's suggestion of applying the strapping from above down so as to facilitate this rubbing is much to be commended. The effect of massage in my own case was absolutely delightful.

While early movement is being carried out the bones may be steadied by the hands of the surgeon or by a temporary clamp located to the injured part. The whole treatment by strapping, early movement, and massage not only gives immediate comfort to the patient but also prevents wasting of muscles and enables the patient to get about much earlier than under the old-fashioned plan of fixation for weeks. Moreover, it prevents the occurrence of that stiffness of joint which so often comes before the surgeon after fractures that have been treated by the ordinary plan.

I am, Sirs, yours faithfully,
E. NOBLE SMITH.

Queen Anne-street, London, W., Feb. 19th, 1905.

DUODENAL ULCER.

To the Editors of THE LANCET.

SIRS,—With reference to "flushing" in the treatment of perforated duodenal ulcers might I refer Mr. W. Bruce Clarke to the series of nine cases of perforated gastric ulcer, eight of whom recovered, published in THE LANCET of July 16th, 1904, p. 145? Seven of these cases were under my care and two were under the care of Mr. T. Crisp English. Since then three cases of perforated duodenal ulcer, two of which recovered, have been treated by the same method of flushing at St. George's Hospital by Mr. English and myself. I feel very strongly from my experience of this flushing or irrigation method combined with suprapubic incision that it is a most efficient method of dealing with perforated ulcers, whether of the stomach or the duodenum.

I am, Sirs, yours faithfully,

Half Moon-street, Piccadilly, Feb. 19th, 1905. G. R. TURNER.

To the Editors of THE LANCET.

SIRS,—In reference to the questions of Mr. W. Bruce Clarke I desire to say:—

Firstly. The difficulty of diagnosis between the perforation of a duodenal ulcer and the perforation of the appendix is sometimes very great; so great, indeed, as to have misled surgeons of unquestioned aptitude in the recognition of these conditions. In my original paper in THE LANCET I showed that in approximately 40 per cent. of the cases of perforating duodenal ulcer that had been submitted to operation the incision had been made over the appendix. In my own expe- [illegible] the patients [illegible] appendicitis. [illegible] ter the lapse of a few hours; after the time, that is, during which the area of pain, rigidity, and tenderness has ceased to be local. After the first few hours the peritoneum along the outer side of the "hillock" and down the ascending colon becomes infected. It may be seen covered with plastic lymph when all other parts of the peritoneum are unharmed. In this stage a confusion of diagnosis is not improbable, for the localisation of the signs mentioned reproduces the circumstances of a case of appendicitis—the "mimicry," in fact, is complete. In the last stage of all, when the peritoneal infection is universal, the discovery of the point of origin of a general peritonitis is virtually impossible. Mr. Bruce Clarke's question may therefore be answered by the statement that in the early hours after a perforation diagnosis should be easy, after a few hours appendicitis may be mimicked, in the last stage of all an accurate diagnosis is extremely unlikely. Nowadays the cases are seen early and [illegible], the difficulty in diagnosis [illegible] es are "earlier recognised [illegible] ing and drainage of the peritoneum is determined entirely by the conditions found. In the first few hours it is not necessary (it is probably harmful) to do either; in the stage of general infection it is my practice to drain freely and, generally, to flush the peritoneum with hot saline solution. The last case in my list (Series 1) was an exemplary instance of the kind of case that would seem to demand irrigation and drainage. The facts that Mr. Bruce Clarke has not, except in the one case mentioned, felt any difficulty in making a correct diagnosis and that he regards the flushing of the peritoneum as unnecessary are both eloquent in proof of the earlier recognition of the cases in his own experience. There are, however, cases, unfortunately still too many, in which the recognition of the disease is tardy; in them difficulties of diagnosis are not unlikely to be encountered and measures necessary for the cleansing of the greatly damaged peritoneum must still be practised. I am, Sirs, yours faithfully.

Leeds, Feb. 20th, 1905. B. G. A. MOYNIHAN.

COFFEE AND SEWAGE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 18th, p. 460, Mr. R. J. Friswell complains of your comment of Feb. 4th on the above as being unfair. In this connexion I should like to point out that, according to Dr. J. W. H. Eyre's examination, each berry acted as a nutritive medium for bacillus coli communis, bacillus enteritidis sporogenes, and sewage streptococci. If the presence of these does not show sewage contamination I should like to know what does. Why is sewage itself dangerous? Because it contains these very organisms and may contain many others more generally recognised as pathogenic. Even were the quantity of sewage small it might be very deleterious because the berries from the way in which they were packed—viz., in bags—acted as a kind of filter bed, freeing the water which passed through them of a large amount both of organic and inorganic filth which became deposited on the surface of the berries. The evidence of the sanitary officials was given on the assumption (uncontradicted) that the coffee during roasting attained a temperature of from 300° to 400° Centigrade, but Mr. Friswell in his letter now states this ought to have been Fahrenheit. Had we understood that 180° C. was the highest temperature we should not have admitted that all organisms were destroyed by roasting, since it is quite conceivable that certain spores may have escaped, not to mention the various cellular toxins. In view of the fact that caffein itself is not destroyed at this temperature I consider it quite an open question whether the products of the various bacteria which infested the berries were rendered harmless.

I am, Sirs, yours faithfully,
R. K. BROWN, M.D. R.U.I.

The Town Hall, Spa-road, S E , Feb. 20th, 1905.

HIGH BAROMETRIC PRESSURE AND CEREBRAL HÆMORRHAGE.

To the Editors of THE LANCET.

SIRS,—I have only just seen the issue of THE LANCET of Jan. 28th in which Dr. James W. Russell of Birmingham has an article on the Relation between Various Atmospheric Conditions and the Occurrence of Cerebral Hæmorrhage. In this he refers to Dr. R Hensleigh Walter as having suggested that there is a relation between a high barometric pressure and an attack of cerebral hæmorrhage. Now, so far as I know, I was the first to suggest the influence of a high barometric pressure upon hæmorrhages generally, including, of course, cerebral. This I did in an article which appeared in 1896,[1] entitled "Hæmorrhages: their Relation to Barometric Pressure." I have drawn your attention to the above article as in recent literature the fact that the relation between high barometric pressures and hæmorrhages had been observed and commented on nearly ten years ago has been entirely ignored.

I am, Sirs, yours faithfully,
Edinburgh, Feb. 18th, 1905 THOS. WHITELAW, M.D. Edin.

SANTA CRUZ, TENERIFFE, AS A HEALTH RESORT.

To the Editors of THE LANCET.

SIRS,—I wish to draw attention to the claims of Santa Cruz, Teneriffe, as a health resort. I refer more particularly to the new suburbs above the English church (from 200 to 300 feet above sea level), where there are now a number of good hotels and pleasant gardens amidst salubrious and picturesque surroundings. The average mean temperature of the winter and spring months is about 65° F., relative humidity 65, and rainfall 11·50 inches per annum. There is an abundance of bright sunshine, the nights are warm, and there is a very slight dewfall. There is generally a pleasant breeze from the sea and altogether it may be considered one of the best climates in the world for invalids or people wishing to spend their winters abroad. The electric tramway from Santa Cruz to La Laguna and on to Tacoronte (a rise of nearly 2000 feet) is a great boon to visitors and during the summer Santa Cruz, which is the capital of the Canary Islands, is a most interesting old city and the most lively in the archipelago. If desired I shall be glad to give any further information.—I am, Sirs, yours faithfully,

A. W. W. DOWDING, M.D. Durh.

Santa Cruz, Teneriffe, Feb. 10th, 1905.

HUNTERIAN ORATORS.

To the Editors of THE LANCET.

SIRS,—It is generally agreed that Mr. J. Tweedy's Hunterian Oration marks a new departure in point of originality and your favourable notice of it will be endorsed by all who heard it. Not only did he offer his audience an unhackneyed appreciation of the work and methods of John Hunter but he had the courage to analyse one of the tiresome rhetorical commonplaces copied from one another by indolent orators half a century ago, according to which Hunter is likened to Bacon. The orator showed that Francis Bacon, great as he was, was the last of the mediæval philosophers, while John Hunter was a pioneer entirely on a higher plane, because more careful of the truth than the Lord Chancellor who is supposed to have written the plays of Shakespeare. Orators have in the past been cruelly hampered by the necessity of always speaking about the same man. In their desire to say something new about John Hunter they have too often unconsciously repeated the veriest platitudes. Sometimes the task has been too much for them. In 1841, for instance, Thomas Callaway failed conspicuously in his oration. He could not decipher his own writing and though more wax candles were brought by Clift, his speech was described as a "most miserable failure." John Flint South in 1844 was original at John Hunter's expense. He omitted to mention him in his oration. Lawrence lost his temper and made a famous attack on the general practitioners who had crowded to hear him (1846). Asked to apologise, he indulged in ferocious repartee and called his audience geese. Luke's oration in 1852 was very poor and Bransby Cooper's "a great failure." The oration of Honoratus Leigh Thomas is described as "a most modest production" in 1827, while Sir Anthony Carlisle simply delivered a lecture on oysters. Hence, his nickname in the pages of THE LANCET[1] of the time, "Sir Anthony Oyster." Similar in kind though far different in degree was Joseph Henry Green's famous oration on "Mental Dynamics," while in recent years Mr. Macnamara lectured very ably on anthropology and but little on John Hunter. Mr. Tweedy's oration is in some sort a return to the typical exercises in which John Hunter has been kept in view as a text, new and appropriate lessons being drawn from his work and his character. As such it will rank among the classics of the College. I am, Sirs, yours faithfully,

P. V.

Feb 20th, 1905

ADVANCED PLUMBING.

(FROM A CORRESPONDENT.)

AN examination of the sanitary fittings and plumbers' work now nearing completion at the new wing of St. Mary's Hospital, Paddington, is encouraging, indicating as it does that the hitherto slow march of the plumber is being brought into time with the quick-step of modern surgery. At St. Mary's Hospital the greatest attention has been given to every detail and the result reveals a unity of purpose in conception and construction which reflects the greatest credit on all concerned. A special feature throughout all the internal fittings is simplicity in form, there being a complete absence of any attempt at ornamentation. Sharp angles are avoided, all necessary mouldings or projections being rounded or hollowed, thus avoiding corners in which dirt and germs could accumulate. Each part of the several fittings is accessible for cleansing, while all unavoidable jointings are flush. There are several deviations from existing work of the kind that are well worth special attention.

Closets.—The closets are of white enamelled fire clay, on the cantilever principle, carefully formed with roomy shallow pans to avoid fouling, and are fitted with a specially constructed flushing rim that insures thorough cleansing.

---

[1] Brit. Med. Jour., May 30th, 1896.

[1] See THE LANCET, Feb. 18th, 1826: "Hunterian Oration read by Sir Anthony Oyster . . His speech was a fine sample, on the whole, of rhetoric, which the learn'd call *rigmarole*."

These closets are built into the wall clear of the ground and the seat is at a lower level than usual. The low level is considered to have certain physiological advantages and it certainly offers a more natural position than the ordinary 17½ inch high seat. The safe beneath in place of lead or the usual more or less absorbent tile is a heavy cast iron tray coated with porcelain enamel and provided with a grating and waste pipe. The lead service and the anti [illegible] ected with adjustable [illegible] y cisterns are of cast [illegible] which form together with the use of a special valve renders them as nearly as possible silent in action. The cisterns are also coated with white porcelain enamel while the lever chains are of a non corrosive metal with celluloid handles.

Commode cupboards.—One very important provision is that of the white porcelain cupboards for the storage of bedpans and urine bottles containing samples awaiting inspection. These are supplied with a novel system of ventilation both inlet and exhaust. The fresh air inlet which is carried through the external wall is fitted with a fine wire gauze moveable panel or fly trap. Thorough ventilation takes place each time the adjacent bedpan sink is used some 200 or 300 cubic feet of air being drawn through the cupboards automatically. This is accomplished thus the water supply to the flushing cistern of the sink is utilised to operate a ventilating fan in its passage to charge the cistern. By this means any extra waste of water is avoided. Where these cupboards are not in the immediate vicinity of the bedpan sinks shafts have been carried up from them fitted with copper exhaust ventilators which are kept in constant action by means of a small Bunsen burner fixed in the shaft.

Scalding sinks.—The bedpan sinks are of one piece of enamelled porcelain with ascending jets for scalding the pans and a special arrangement for urine bottles. The jets are controlled by self closing non concussive gun metal valves. The basins or hoppers of these sinks are flushed by three gallon cisterns similar to those used for the water closets. Porcelain corrugated slabs are supplied in connexion with these sinks provided with hose and hand sprays for scouring mackintosh sheets.

Surgical sinks.—The surgical sinks have naturally received most careful attention. The adoption of a toe action combined hot and cold valve would seem to be a considerable improvement on the pedal valves previously in use as the slightest tap of the toe instantly controls both the quantity and the temperature of the flow while there is no necessity for maintaining a regular pressure as with the pedal, necessarily by doing away with the pedal, the fitting is rendered less complicated. The sinks themselves are of white porcelain with rolled edges and fitted with recessed accessible wastes which last are removeable for sterilising. The sinks are in pairs and between each is fixed a polished gun metal wringer for use when cleansing sponges &c. The hot and cold supply is delivered through overhead swing brackets having a spray and douche attached. In connexion with these sinks are porcelain draining trays for cleaning instruments. Glass shelves for the disinfectant bottles are also provided which last have vulcanite valve stoppers.

Lavatories.—Adjoining the operating room is the surgeons room in which are three large plain porcelain lavatories each one being fitted in all respects like the surgical sinks only the wastes are governed by a slide arrangement and can be opened or closed by a touch of the elbow the wringers of course excepted. The whole of the metal used is non corrosive. The baths sinks and other plumbers work throughout the building are all of a proportionately high standard. The nurses sinks are fitted with specially porcelain enamelled Berkefeld filters. Water storage is provided for two days supply and a small auxiliary electric motor has been fixed in order to insure their being charged in the event of the pressure failing in the water company's main.

Great credit is due to the architect Sir William Emerson and the hospital staff for the foresight and care shown in the details as also to Messrs Davis and Bennett the contractors who have carried out the work. It may be added that only registered plumbers have been employed.

TORBAY HOSPITAL, TORQUAY.—£1800 have been received by the governors of the Torbay Hospital Torquay, in response to their appeal for £2000 for the purpose of providing a children's ward and a new operating theatre.

SMALL POX AND SLUMS AT PITTSBURG AND ALLEGHENY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

IN visiting what I was informed were considered to be the slums of Boston I only found one small group of houses which were inhabited by organ grinders and which might be qualified as really bad. At Pittsburg and Allegheny there was no difficulty in discovering slums well worthy of comparison with the lowest quarters of large English industrial centres. The towns which have developed very rapidly in consequence of some newly created industry do not seem to be administered so well as the more ancient and historic towns and cities where the growth in size and trade has been more slow and more deliberate. Then there is one marked difference. In the older towns or cities the great difficulty is to find land to build upon in the newer towns the difficulty is to find land that has been built upon. At Pittsburg there are vast stretches of elevated land outside the city where a large district of villadom is fast springing into existence. The result is that whole streets of more closely packed houses built near the centre of the city which served as residences for the well to do before electric trams came into existence are now handed over to the poorer sections of the community. These in some instances have degenerated into slums. Of course the land in the business centre of the city has become extremely valuable and there the houses consist of offices with but very few inhabitants. Indeed to make still more use of the land sky scrapers have been built one of these being no less than 28 storeys high. It is to be hoped that measures will be taken here as at Boston to limit this style of building for though a skyscraper or two may not do much harm except it be by reason of its ugliness a large number would so shut out the air and light from the streets as to constitute a considerable danger to the public health. What the town may become may be inferred by the bargain made by one of the churches. The length of this church ran parallel with the street and thus it occupied a good deal of frontage. The church thereupon sold half the frontage to a skyscraper building company. Besides paying a considerable sum of money this company pulled down the church at its own expense and then rebuilt it the other way round—namely at right angles with the street instead of parallel. Thus only the narrow end of the church faces the street and on the frontage space vacated a huge 'skyscraper containing many hundred offices and business premises towers above the church and its steeple. Instead of driving the money changers out of the temple the land on which the temple stood has been sold to the money changers.

It has already been explained that in spite of the immense wealth accumulated at Pittsburg there is no proper water supply and typhoid fever prevails in an endemic condition which occasionally bursts out into an epidemic.[1] An administration [illegible] nated water to [illegible] ticular care on t[illegible] sewage. There is no sewage disposal scheme before the municip[illegible] the least likely to save the city. A [illegible] water now drunk is [illegible] ers is to be met by introducing meters and making a charge in proportion to the quantity consumed a method which will not encourage poor people to take baths. But there are legal difficulties in the way of this scheme that could well supply pretexts for indefinite postponement. Yet there have been many warnings as to the general insanitary condition of Pittsburg. As soon as the temperature rises to about 80° F there is an abnormal prevalence of infantile diarrhoea. The sanitary department does a good deal of work in endeavouring to cope with existing evils. On the receipt of a message from a medical practitioner municipal inspectors examine the plumbing the drains and the water supply of any house which is considered to be in an insalubrious condition. It often happens that the inhabitants are found to be drinking contaminated water from a private well and they are then given the contaminated public water supply by way of change. When there is a case of infectious disease in a house the authorities affix a "plague card" on the door and prevent any unnecessary visiting. If it is a case of small-pox the watch kept is more strict. The isolation enforced lasts three weeks.

---

[1] See Typhoid Fever and the Water-supply at Washington Pittsburg and Allegheny THE LANCET Nov 19th 1904 p. 1451

It has been noted that foreigners do not suffer from small-pox because they have all been vaccinated on board ship or just before crossing the Atlantic. But their children, born in America and under the school age, are very liable to this disease. At school they are vaccinated and then the danger ceases. After a death from small-pox or the removal of the patient to the hospital the method of isolation imposed on those who have been in attendance or have lived in the house is modified. After thorough disinfection those who have been vaccinated successfully and who are now revaccinated are allowed to go out and their movements are not restricted though they are watched. For 20 years Pittsburg had been almost free from small-pox, then an epidemic began in 1898, assumed a severe type in 1902, and the last fresh case was notified in June, 1904. Vaccination was very generally neglected except by foreigners and school children as explained above. Before any child can be admitted to school a fully qualified practitioner must certify that he or she has been successfully vaccinated; thus above the age of six years all children are vaccinated. The sanitary authorities as a result of their inquiries came to the conclusion that previously to the outbreak of small-pox only about half the population of the city had been properly vaccinated. Thereupon visits were paid and persons known not to be vaccinated were constantly disturbed by the authorities and by bringing various forms of pressure to bear the majority ultimately consented to be vaccinated. Nevertheless, it is estimated that there are still some 70,000 persons at Pittsburg who have not been vaccinated out of nearly half a million people. Though there had been a good many cases of small-pox previously only three deaths had occurred from that disease since it first appeared in 1898 up to the commencement of 1903. By that time a much more severe type prevailed and altogether there have been some 450 deaths from small-pox. Fortunately an isolation hospital had been built in 1876 and there is now a newer and better fever hospital, consisting of two separate pavilions—one for small-pox and the other for diphtheria. From this municipal hospital diphtheritic antitoxin is gratuitously distributed and at the bacteriological laboratory sputum and other material in regard to diphtheria, typhoid fever, &c., are examined for the medical profession. The authorities also notify schools whenever they ascertain that there is a case of infectious disease in the home of any of the pupils. This precaution is taken in regard to measles as well as for scarlet fever, diphtheria, &c. The children are not only prevented from going to school but they are not allowed to frequent libraries or other places of public resort.

In order to cope with infectious disease and to prevent nuisances the staff of the sanitary department is certainly undermanned. There are but two inspectors, for instance, for the tenement houses. The boarding houses are notoriously overcrowded. There are not, however, many coloured people at Pittsburg. The negroes do not number more than about 5 per cent. of the total population but their death-rate is nearly twice as high as that of the white people. The white population should live in good sanitary surroundings. There is no poverty such as we see in England. Some artisans earn wages that many of the middle classes of England would envy. Not a few workmen's wages amount to £300 a year and some of the more skilful steel plate rollers and workers and foremen, especially if they have a royalty on the output, make from £2 10*s.* to £4 per day. One well known artisan by the royalty system made £10 per day and retired with a fortune. Of course it must be borne in mind that the cost of living is much higher, though the raw materials are not so much more expensive. A family that will do its own cooking and domestic service can live nearly as cheaply as in Europe. Then, from the sanitary point of view, it is not the earnings of the exceptionally well-paid artisans that govern the situation. On the contrary, it is the worst paid who are the more important and interesting. The slums of Pittsburg are not inhabited by the highly skilled American artisan. He very often resides in a villa built in the outskirts of the town. The slums are peopled by the newly arrived foreign labourers who are ready to do the low class of work which the American will not touch. For such work the foreign labourers receive much higher wages than they would obtain in their own country; while their womenfolk generally know better than the Americans how to cook and how to economise their food and fuel. For instance, an American will not work at the building of a sewer for less than 12*s.* a day; but there are Italian labourers and others who will do the same work for 6*s.* a day and save money on this wage. Some of these men are so anxious to economise enough to get back to their own country that they will even seek to save in rent by living in what are called "double-shift dormitories." Here the beds are occupied by a set of day tenants who work at night and by another set of night tenants who work in the day time. This I found to be the case both at Allegheny and at Pittsburg. The one object especially with the Italians, the Hungarians, and the Austrian Slavs is to save their money and to return home, for in America, and especially in Pennsylvania, there is no knowledge of the joys of life, there is no sense of enjoyment, no capacity for pleasure, as these people understand it. So they will live on dry bread and a little sausage, for this they can carry with them and thus avoid the extravagant charges and the bad cooking of American restaurants and eating houses.

The homes of some of these people which I visited both at Pittsburg and at Allegheny were quite as deplorable in appearance and as unfit for human habitation as those which may be seen in the slums of old European towns. At Pittsburg there were the same irregularity of structure, the same narrow passages between dilapidated houses, and the same malodorous inner yards devoid of pavement and of sufficient light and air, as may be seen in the older countries. The people were huddled together. Some kept small shops and slept on shelves in the shops over the goods which they had for sale. The beds were often placed in the centre of the building away from the windows and the possibilities of efficient ventilation. This was especially the case in the Italian quarter of Pittsburg.

The better class of workmen, notably the Germans as well as the Americans, join building societies and through this agency succeed in time in purchasing their own homes. They are also anxious to give their children the full benefit of public school education. But the Hungarians and the Slavs are more desirous to work their children, so that they also may earn a little and thus hasten the happy day when enough money will have been saved to return to Europe. However, there has been a beneficent interference on the part of legislation. The law compels all children to go to school when they are from six to seven years of age and the Factory Law forbids the employment of children under 13 years of age. So now the Slav children go to Croatian schools that have recently been built by the Roman Catholics so as to prevent their receiving an American education while enabling them to comply with the American law. At Allegheny there is a lady inspector of the poor quarters who very courteously gave me information concerning the way in which some of the worst paid workers live. For instance, on one occasion it was found that ten different families were lodging together in a house that consisted of only seven rooms. There were often four beds in a room and two men sleeping in one bed. Cellars are yet to be found under dwellings that are packed with living poultry and pigs. These are done away with as soon as they are discovered. On the whole, the agents who represent the owners of the houses are ready to comply with the demands made by the sanitary authorities and to carry out the improvements suggested. Some of the worst houses were even pulled down and rebuilt and a very sharp watch is kept to prevent the accumulation of rags, refuse, and dirt in unoccupied cellars. The rent generally charged is from £1 8*s.* to £1 12*s.* per month for a tenement of two rooms. Many of the houses thus let in tenements at Allegheny are only three storeys high and the stairs are outside the walls so they do not serve to convey foul air from one tenement to the other tenements. Accompanied by one of the sanitary inspectors I visited some of the poorer quarters of Allegheny and found a single room near a sweetstuff shop tenanted by no less than eight Greek men. Then in the basement there were 16 men. In a tenement of two rooms I found ten people and they paid between them £1 5*s.* per month. Here a tame rabbit was playing about and there was a very filthy closet. As these people earn at least 4*s.* a day when in work they could surely pay a higher rent.

change. When there is a case of infectious disease in a house the authorities affix a "plague card" on the door and prevent any unnecessary visiting. If it is a case of small-pox the watch kept is more strict. The isolation enforced lasts three weeks.

It has been noted that foreigners do not suffer from small-pox because they have all been vaccinated on board ship or just before crossing the Atlantic. But their children, born in America and under the school age, are very liable to this disease. At school they are vaccinated and then the danger ceases. After a death from small-pox or the removal of the patient to the hospital the method of isolation imposed on those who have been in attendance or have lived in the house is modified. After thorough disinfection those who have been vaccinated successfully and who are now revaccinated are allowed to go out and their movements are not restricted though they are watched. For 20 years Pittsburg had been almost free from small-pox, then an epidemic began in 1898, assumed a severe type in 1902, and the last fresh case was notified in June, 1904. Vaccination was very generally neglected except by foreigners and school children as explained above. Before any child can be admitted to school a fully qualified practitioner must certify that he or she has been successfully vaccinated; thus above the age of six years all children are vaccinated. The sanitary authorities as a result of their inquiries came to the conclusion that previously to the outbreak of small-pox only about half the population of the city had been properly vaccinated. Thereupon visits were paid and persons known not to be vaccinated were constantly disturbed by the authorities and by bringing various forms of pressure to bear the majority ultimately consented to be vaccinated. Nevertheless, it is estimated that there are still some 70,000 persons at Pittsburg who have not been vaccinated out of nearly half a million people. Though there had been a good many cases of small-pox previously only three deaths had occurred from that disease since it first appeared in 1898 up to the commencement of 1903. By that time a much more severe type prevailed and altogether there have been some 450 deaths from small-pox. Fortunately an isolation hospital had been built in 1876 and there is now a newer and better fever hospital, consisting of two separate pavilions—one for small-pox and the other for diphtheria. On the whole, the agents who represent the owners of the houses are ready to comply with the demands made by the sanitary authorities and to carry out the improvements suggested. Some of the worst houses were even pulled down and rebuilt and a very sharp watch is kept to prevent the accumulation of rags, refuse, and dirt in unoccupied cellars. The rent generally charged is from £1 8*s*. to £1 12*s*. per month for a tenement of two rooms. Many of the houses thus let in tenements at Allegheny are only three storeys high and the stairs are outside the walls so they do not serve to convey foul air from one tenement to the other tenements. Accompanied by one of the sanitary inspectors I visited some of the poorer quarters of Allegheny and found a single room near a sweetstuff shop tenanted by no less than eight Greek men. Then in the basement there were 16 men. In a tenement of two rooms I found ten people and they paid between them £1 5*s*. per month. Here a tame rabbit was playing about and there was a very filthy closet. As these people earn at least 4*s*. a day when in work they could surely pay a higher rent.

The inspector assured me that the unskilled workers could earn 6s. a day while the skilled mechanics obtained from 12s. to 14s. a day. Even making some allowance for the tendency to exaggerate the amount of wages paid or to omit the number of days when there is no work whatsoever to be done, the working class can afford a sufficient rent to live in healthy houses. In England the difficulty is that it is often literally impossible for the unskilled to earn enough to pay a rent that will cover the cost of building proper dwellings. With labourers' wages at 18s. and 20s. a week how can they pay enough rent to house themselves and their families? But at 6s. a day or 36s. a week the position would be very different. In England it is often so obvious the *tenants cannot help overcrowding that neither sanitary* inspector nor magistrate has the heart to enforce the law. In America the same excuse does not hold good, at least, to the same extent Much more space is still vacant to build upon and there is more money to pay for the building.

On the other hand, the importance of these problems is not so keenly appreciated—in any case not at Pittsburg or Allegheny. The energy of the sanitary authorities is devoted rather to combating outbreaks of infectious disease than to attempting to remove the predisposing causes. Thus, at Allegheny a considerable amount of money is spent in distributing gratuitously to rich and poor alike anti-diphtheritic toxin. This item alone costs £500 a year out of the public funds. The bacteriological laboratory was established in 1896 and received during the first year of its existence 420 specimens for examination. The fact that in 1903–04 the number of specimens sent amounted to 1004 shows the growing appreciation and usefulness of this institution. If by the examination of the sputum or through any other agency it is found that there are several cases of tuberculosis in a building the sanitary authority sends its staff to disinfect the premises. These are all good points but nevertheless the sanitary department is not what might be expected for a town of such importance and where so much wealth exists. A mere glance at the building occupied by the Bureau of Health shows that both the citizens and the city corporation are without any real appreciation of the importance of the sanitary services. This bureau consists of a miserable little red brick building with the upper part let to some tenant, while the public services below are cramped for want of space. The bacteriological laboratory, for instance, is only separated by a door from the offices frequented by inspectors who visit all the neighbouring fever dens. Yet this bureau stands in the middle of vacant ground where there is plenty of room to build proper municipal offices and laboratories. Not only does the vacant ground remain unutilised but there is no scavenging done. Against the very walls of the sanitary department and in the surrounding vacant space there is an unseemly and dangerous accumulation of rags, old stockings, old boots, waste paper, broken pots and pans, fragments of food, egg shells, rotten fruit, underclothing soiled with fæcal matter, mud, and urine. Such was the sort of refuse which I found had been dumped down against the very walls of the bureau where the municipal officers are expected to watch over the health of the city of Allegheny. Also I noted that in front of all this garbage, which the city scavengers are allowed to neglect and do not trouble themselves to remove, is placed a rough wooden bench where persons who have business at the bureau can sit in the open and wait and breathe the dust blown upon them from the accumulation of refuse that is spread out behind them. All this is in the very heart of the city. Facing the bureau is the principal square where the town-hall and the post-office stand and these, at least, are buildings that have some slight architectural pretensions. Behind the bureau are a few streets where I was surprised to find an extraordinary number of dead rats lying about in the gutters or on the causeway. Then but a few steps beyond is the public park, with its trees, its flowers, its band-stand, and its loiterers who go there to breathe purer air and to rest. Certainly such parks are most necessary as breathing spaces in large towns but it is also necessary to keep the air in the street as pure as possible. This can only be done by careful drainage and prompt energetic scavenging.

VACCINATION GRANT.—Mr. Philip E. Hill has been awarded for the fourteenth time in succession the Government grant for efficient vaccination in the Crickhowell district of the Crickhowell union.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Teaching of Hygiene and Temperance.

AT the last meeting of the Birmingham education committee the report of the subcommittee upon the circular from Sir William H. Broadbent, in which he urged the importance of the compulsory teaching of hygiene in public elementary schools, was considered. The committee was of opinion that, much as it would like to fall in with Sir William Broadbent's suggestion, it was inadvisable to add to the number of subjects already taught in the schools. It drew attention to the fact that in the teaching of the subjects already in the curriculum considerable time was spent in inculcating the principles of hygiene; that it had lately appointed two peripatetic science teachers who were interested in hygiene; and that the Band of Hope Union representatives were allowed to visit the schools. At the University a short course of lectures on ambulance work and hygiene is in process of being delivered by certain members of the staff. Intended primarily for students of mining it has by request been thrown open to all members of the University. The Worcester education committee has appointed Miss Anstey of the Halesowen Physical Training College to give a course of instruction to the female elementary school teachers in physical culture. It was no doubt also an interest in hygiene and a belief in its importance which prompted the West Bromwich Trades Council to write to the West Bromwich education committee urging the advisability of a medical examination of all the children attending the elementary schools.

The Licensing Sessions.

On the first day of the above sessions a deputation waited upon the magistrates and presented the "citizens' memorial," in which, while deploring the increase of drunkenness, the signatories noted with satisfaction the increase in the number of cases in which the responsibility for permitting drunkenness on licensed premises had been brought home to the licensees. They were of opinion that the number of licensed premises was excessive and that many of them were structurally deficient and unsuitable. They wished to express the hope that the magistrates would not sanction the removal of valueless licences from congested areas to uncontaminated districts or grant occasional drink licences to council schools. The deputation was given a very cordial reception and in reply the chairman said that he did not think there had been any increase in drunkenness, that he wished to see not only fewer public-houses but better ones, and that the magistrates attached much importance to the maintenance of the friendly relations already existing between them and the brewers. He further stated that it was the intention of the magistrates to give notice that they wished to put an end to the licences of 36 houses, 21 of which were in the Floodgate-street area. 14 of the houses were fully licensed houses, 20 were beerhouses, and two had beer and wine licences The number of premises licensed for the sale of intoxicants was at the beginning of the sessions 2103 as against 2163 last year. This works out at one licensed house for every 258 inhabitants in the city. In addition to the sale at these houses a very considerable amount of "beer-hawking" takes place; one brewer stated at the sessions that the company in which he was interested sold to more than 15,000 separate families.

Birmingham and Wye Compensation Water.

At the annual meeting of the board of conservators, Wye Fishery District, the proposal of the Birmingham Corporation to reduce the Wye compensation water by 7,000,000 gallons a day was considered and in view of the unanimous opposition to the proposal by the various local councils it was resolved that the Birmingham corporation should be requested to withdraw from its Bill the portion relating to the reduction of the compensation water. To this the Birmingham authorities have agreed.

Asylum News.

At a special meeting of the lunatic asylums committee held a short time ago the question of the provision of separate accommodation for private patients in the city asylums was considered. The committee hopes that on the opening of Hollymoor Asylum it will be possible to place two separate wards at the disposal of the private patient class and it is not unlikely that some such accommodation will also be available at the smaller establishments of "The Leveretts" and "Glenthorne." Representatives of the asylum authorities in the boroughs of Birmingham and Leicester and the counties of Warwick, Worcester, Stafford, Derby, Nottingham, Gloucester, and Leicester met on Friday last at the council house, Birmingham, to consider the ways and means of providing accommodation for juvenile idiots and imbeciles certified under the Lunacy Acts and at present resident in county and borough asylums. It was felt that the present system of detaining idiot and imbecile children in the wards of public asylums was bad in that it had a depressing effect upon adults suffering from curable mental disease and also prevented the proper training and education of those children capable of receiving such. After a long discussion a resolution was passed expressing approval of the principle of separating juvenile idiots and imbeciles from the adults in asylums and undertaking to recommend the respective authorities to adopt some combined scheme, with the object of having one joint institution for the Midlands in order that a saving might be effected in expenditure. A subcommittee was appointed to formulate a scheme in accordance with the resolution.

The Unemployed.

The question of the unemployed is demanding more and more the attention of the public bodies and a conference is shortly to be held between the city council and the various boards of guardians to consider some scheme of providing work for persons requiring relief, both as a temporary employment for respectable men and as a test for doubtful cases. Mr. Fels of Philadelphia has offered to lend land to the guardians for the purpose of forming a labour colony, on the understanding that should it prove successful the guardians will purchase the land at the price given for it. The advantage of such a scheme is that work will be found for unskilled labourers and that it will not result in the displacement of other labour. The general feeling seems to be in favour of the acceptance of Mr. Fels's offer. The success of the scheme is believed to depend upon the labourers being induced to stay long enough on the land to become efficient cultivators. No doubt some conclusion will be arrived at as a result of the conference, for it is felt that something must be done without delay to check the steady increase of expenditure year after year for Poor-law purposes.

Health of Birmingham.

The death-rate for the week ending Feb. 4th was 17·1, the zymotic death-rate for the same period being 1·5. The increased mortality was due to measles, diphtheria, pulmonary tuberculosis, and diseases of the respiratory organs. For the week ending Feb. 11th the death-rate and zymotic death-rate were 16·2 and 1·2 per 1000 respectively. A pavilion at Little Bromwich Hospital has been reserved for cases of diphtheria and now contains 16 patients. Dr. A. Bostock Hill's report upon the health of Castle Bromwich rural district for the year 1904 states that there has not been a single death registered from pulmonary tuberculosis.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Fatal Case of Plague in the Mersey: Prosecution of the Master of the "Crewe Hall."

THE master of the s.s. *Crewe Hall* was summoned at the Liverpool police court on Feb. 15th before Mr. W. J. Stewart, the stipendiary magistrate, charged with having contravened Section 23 of the Public Health Act, 1896, by neglecting to answer truly questions put to him by a Customs officer as to the health of all on board during the voyage of the vessel. Mr. Cripps, the prosecuting solicitor, said that the officer boarded the vessel and asked the usual question of the master as to the state of health of all on board, who, in reply, said "All is well." The vessel then docked and afterwards a dying lascar was found on board. From the log it appeared that the man had been ill for some days in his bunk and that his temperature varied between 105° and 101° F., so that he must have been seriously ill. The defendant's excuse was that he thought the man was suffering from a cold, but in any case the answer that all was well was certainly wrong and he ought to have told the port sanitary authority that he had a man with a high temperature lying ill in his bunk. The defence was that the master had no suspicion that the lascar was suffering from an infectious disease. Mr. Stewart interposed by saying that he was not prepared to say that there was no responsibility thrown on the captain or that he could get rid of it by saying that the illness was trivial. That would leave it entirely at the discretion of the master to disclose it or not. The position of the medical officer was this: "I do not care what the illness is, or what you thought it was; tell me of it and I will say whether it is safe for the Port of Liverpool to allow you to land." The captain very unwisely took upon himself to state that there was no illness on board his ship; there were facts in his mind which he ought to have disclosed and which were certainly material. The stipendiary came to the conclusion that there had not been a deliberate suppression of facts in order that the vessel might get into dock to discharge passengers and cargo without any trouble; but it was important that the master of a ship should not take the responsibility of being the judge himself. The defendant was fined £10 and costs. Dr. W. Hanna, the assistant port medical officer, in his evidence stated that the lascar died from plague pneumonia, the presence of plague bacilli having been ascertained (on post-mortem examination) microscopically and bacteriologically, as stated in THE LANCET of Feb. 18th, p. 444.

The Housing Problem in Liverpool.

Colonel Slacke, R.E., conducted an inquiry on Jan. 26th on behalf of the Local Government Board in reference to an application by the Liverpool corporation to borrow £35,000 for the purchase and demolition of insanitary property under the powers of the Liverpool Sanitary Amendment Act, 1864. Mr. Cripps, the assistant town clerk, in stating the case, said that under that Act it was the duty of the medical officer of health to report to the council on any houses in the city which he considered to be unfit for habitation. Up to the present the council had always ordered the houses to be demolished and under that Act it had already spent £400,000 in purchasing property for demolition. Between 7000 and 8000 houses had been demolished and there were still left to be dealt with 8000 or 9000 dwellings of a similar type. The corporation had given a pledge to rehouse 50 per cent. of the people dispossessed, and since 1899 some 4313 persons had been provided for, leaving 158 still to be dealt with. In order that the inspector might arrive at an opinion as to whether that pledge was to be continued, increased, or diminished he mentioned that a return of the head constable showed that the number of vacant houses with a rental of 5*s.* per week and under was 1143 and of £20 a year and under 3150, a total of 4293. Since 1901 the corporation had demolished about 1500 houses. The reason for the large number of vacant houses in the centre of the city was because the corporation had perfected its electric tramway system and there had been a large amount of building on the outskirts of the city. Houses of all classes were being erected at the rate of 2000 a year. The inspector observed that he had been very much interested in hearing what the corporation was doing. Knowing that it had done more than had been undertaken by any other municipality that he knew of and had dealt satisfactorily with this great problem, he intended to make himself thoroughly acquainted with the nature of the accommodation which it was providing for the people. Colonel Slacke subsequently visited several of the demolition areas and some of the corporation dwellings.

Treatment of Epileptics and Imbeciles in the Liverpool and West Derby Unions.

At a meeting of the West Derby guardians the clerk presented a memorandum of agreement entered into between the representatives of the Liverpool and West Derby guardians with regard to the treatment of imbeciles and epileptics in the two unions. By this agreement the epileptics are to be dealt with by the Liverpool select vestry to the extent of 250 cases and the imbeciles to the same number will be treated by the West Derby union, the effect of this arrangement being that each union will not now be compelled to provide separate accommodation for each class of patients.

Liverpool Hospitals and Corporate Help.

At the annual meeting of the supporters of the Royal Southern Hospital held on Feb. 13th in the town-hall, the treasurer reported that there was a balance due to the bank of £6387, which was an increased deficit for the year of £1100 Need was expressed for a new out-patient department and the Lord Mayor, who presided at the meeting advised the committee to appoint a deputation to wait upon the finance committee of the city council with the object of securing financial assistance for the hospital —At the annual meeting of the subscribers to the Cancer and Skin Hospital held on the same day, an urgent appeal was made for increased funds and the opinion was expressed that in view of the large number of patients received from outlying districts it would be most acceptable if some of the district councils or other local bodies would arrange to vote an annual grant in aid of the funds of the hospital

(FROM OUR OWN CORRESPONDENTS)

Barry Health Report

THE annual report of the medical officer of health of Barry is of interest because the town is of recent growth and has been built up under the supervision of a sanitary authority the members of which have endeavoured to insist upon modern requirements being complied with The population of the town—if town it could then be called—in 1881 was 494 ten years later it was 13 278 and in 1901 it was 27 030 The vast majority of the houses are of the type usually occupied by artisans, they are built in rows and are let at weekly rentals varying from 4*s* to 10*s* Each house has a separate drain and a secondary means of access at the rear Barry has been provided since 1900 with a destructor capable of destroying 30 tons of refuse daily, though at present only about half this quantity is dealt with There are no private slaughter houses but in the public abattoir over 10,000 animals were slaughtered during 1904 and no seizures of meat unfit for human consumption were made The hospital, which was erected for the isolation of cases of infectious disease other than small pox has been held in readiness for patients suffering from that disease and has never been put to its proper use but the medical officer of health (Mr George Neale) states that the district council has under consideration the erection of a small pox hospital The death rate from all causes in Barry during 1904 was 11 4 per 1000 In the previous ten years the average death rate was 14 2 per 1000 In calculating these rates no account has been taken of persons resident in Barry who died in public institutions outside the district such as the county asylum, the Cardiff Infirmary or the workhouse Mr Neale draws attention to the large number of complaints regarding the want of systematic cleaning and painting of the forecastles in vessels arriving at Barry, no less than 431 of the 2966 vessels inspected during 1904 having to be dealt with by the port sanitary inspectors There appears he says, to be an increasing disposition amongst many of the mixed crews that now man so many British vessels not to do more than the most superficial work as regards cleaning and painting their berths Samples of drinking water collected on board 20 vessels were examined during the year at the Cardiff and county public health laboratory and only two were reported to be good Five were fairly satisfactory, 12 were unsatisfactory, and one was bad

Somerset and Bath Lunatic Asylum at Wells

There were 45 applications for the position of medical superintendent to the Somerset and Bath Lunatic Asylum at Wells, rendered vacant through the death of Dr C F Laing who was recently drowned at sea and who had held the superintendency for nearly four years The joint committee on Feb 17th elected Mr George S Pope L R C P, L R C S Edin, L F P S Glasg, who has been for the past seven years superintendent of the Middlesbrough Borough Asylum at Cleveland The salary attached to the appointment is £600 per annum with furnished house and other emoluments

Cookery in Elementary Schools

The Somerset county education committee has instructed a subcommittee to prepare a scheme for the provision of suitable instruction in cookery and the hygiene of food in the upper standards of the public elementary schools in the county

Death of Mr Horace Vavasour Sandford, L R C P Lond

Mr H V Sandford, who died on Feb 5th at the age of 78 years was one of the first medical officers of health to be appointed to a combined sanitary district having been elected medical officer of health of the city of Hereford and for several urban and rural districts in 1874 Owing to failing health he resigned all his appointments in 1899 As a pioneer he carried out much useful public health work and his series of annual reports which were printed from the first, contain a great deal of valuable statistical information

Pontypool Hospital

The first year of the Pontypool Hospital appears to have been a very satisfactory one The 19 beds were occupied by 148 patients and the cost per bed was £61 4*s* As might be expected in a colliery district such as that surrounding Pontypool operative treatment was necessary in nearly one half of the cases admitted The income for the year amounted to £1595 and the expenditure was £1211

Newport and Monmouthshire Hospital

The additional expenditure entailed in the administration of the new hospital buildings at Newport (Mon) has resulted in the presentation of a less favourable balance sheet than was the rule in former years The expenditure during 1904 was £5218 and the year's working resulted in a balance on the wrong side of £232 making a total adverse balance of £560 Towards the income of the institution the workmen of the town and neighbourhood subscribed the large sum of £1600 or £123 more than in 1903 The in patients numbered 960 and the average stay in hospital of each patient was 29 days so that those who are responsible for the management of the hospital cannot be accused of extravagance There were also treated during the year 3483 out patients and 1231 casualty patients

Royal Devon and Exeter Hospital

The 168th report of this institution which has just been issued states that 1420 in patients were admitted during 1904 as compared with 1317 in 1903 The out patients numbered 5568, an increase of 598 over the figures for the previous year The financial statement shows that the total receipts for the year amounted to £8448 the expenditure being £9696 During the year Mrs Nosworthy of Dawlish gave £1000 to reconstruct and to furnish the operating theatre in accordance with modern requirements Last April a collector was appointed to solicit donations for the hospital and by his exertions the sum of £449 has been raised

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

The Annual Dinner of the Royal Medical Society Edinburgh

THIS dinner which is an annual gathering of considerable medical interest was held on Feb 14th The invitations to guests are issued by the presidents of the society, of whom there are four The senior president occupies the chair while the other three act as croupiers The presidents are all young graduates who as students, have been active members of the society The special interest of these dinners depends, however on the fact that there is always a guest of the evening selected because of his eminent position in the domain of medicine The guest this year was Professor Ronald Ross C B, F R S After the usual loyal and patriotic toasts the chairman, Dr H N Fletcher proposed the toast of the evening He sketched the great work which Professor Ross had done in connecting malaria with the mosquito and the skill and persistence which he had displayed in his investigations Professor Ross made a long and interesting speech in reply He referred to the number of young men at present engaged in the study of tropical diseases and to the admirable work that they were doing In connexion with malaria he spoke warmly and earnestly of the great difficulty in getting the authorities in this country or in the colonies to take the measures necessary for improving local hygienic conditions He was of opinion that we should think less and act more, and referred approvingly to the prompt action of the Americans in Havana when it was shown that yellow fever was communicated by mosquitoes, the result of their action being that yellow fever was banished forthwith. He also referred to the action of the French in Ismailia, action which had almost banished malaria from that town. The dinner was altogether most successful and the presidents are to be congratulated. Among other guests present were the Lord Provost of the city, the Lord Justice Clerk, and the Bishop of the Episcopal Church.

Vacancies at the Edinburgh Royal Infirmary.

Owing to the death of Dr. A. L. Gillespie there is a vacancy in the medical registrarship at the Royal Infirmary, and Dr. A. Goodall, Dr. C. M. Pearson, and Dr. A. Dingwall Fordyce are all candidates for the post. Dr. J. M. Beattie, one of the assistant pathologists to the Royal Infirmary, who is also senior assistant in the pathological department of the University, has resigned his post in the infirmary and it is being sought for by Dr. G. Lyon, a University assistant, and by Dr. W. T. Ritchie.

The University of Glasgow.

There are among those upon whom the Senate at its meeting on Feb. 16th resolved to confer the honorary degree of Doctor of Laws (LL.D.) two in whom the medical profession are specially interested. These are Alexander Crum Brown, M.D. Edin., D.Sc. Lond., F.R.S., professor of chemistry in the University of Edinburgh, a position which he has held since 1869; and Sir William Whitla, M.D. R.U.I., L.R.C.P. & S. Edin., professor of materia medica and therapeutics, Queen's College, Belfast.

The Outbreak of Typhus Fever in Aberdeen.

In his monthly report Dr. Matthew Hay states that from the commencement of the outbreak to the end of December there were 34 cases with nine deaths; during January 32 cases with five deaths; and in the first half of February 34 cases with one death; making a total of 100 cases with 15 deaths. The mortality has greatly decreased though the cases are increasing and fewer cases under middle age are dying as the epidemic progresses. Up to the end of December the ages of the fatal cases ranged from 18 to 62 years, three being below and six above 40 years; while during January they ranged from 44 years to 62 years. The age of the one person dying during the first half of the present month was 41 years. Of the 100 cases six were children of five years and under, and in 41 cases the ages ranged from five to 15 years. Of the 23 cases in which the ages were from 15 to 25 years there were two deaths, and there was also a death among the 13 cases in which the ages were from 25 to 40 years. The death-roll was heaviest between 40 and 60 years, 10 of the 15 cases dying. Two persons over 60 years were attacked and succumbed. Regarding these figures, Dr. Hay remarks that the most distressing feature is the very high mortality among persons above 40 years of age. Of the 17 persons above this age 12 have died. This is in striking contrast with the low mortality among persons below this age—83 cases with three deaths. If typhus fever, like measles or whooping-cough, were confined—by the immunity of older persons through previous attacks—to young persons it would be considerably less dangerous than almost any of the common zymotics. It is the very high mortality among older persons which invests it with its popular and traditional terrors. As to the distribution of the cases among households it is of interest to note that 75 of the 100 cases were confined to 15 families, ranging from three cases in each of five families to eight cases in one family and nine in another. For three months the disease remained undiscovered in the city, no means whatever being taken to isolate the sick and to prevent the spread of the infection, and yet only 34 cases are known to have occurred during this period. In no case during this period has the disease, so far as is known, been communicated through contact with an intermediary. No clue has yet been obtained as to the primary source of the infection.

University of Aberdeen Medical Society.

The last meeting for the session of this society was held on Feb. 17th. Dr. James Clark having read an interesting paper on Visceral Pain, the reports of the secretaries and the treasurer were read and adopted. These showed the society to be in a flourishing condition. The following office-bearers were then elected:—Honorary president: Professor J. T. Cash. Presidents: Mr. A. S. Leslie and Mr. W. M'Kerrow. Secretaries: Mr. J. F. Gill and Mr. T. Chalmers. Treasurer: Mr. E. K. M'Kenzie. Committee: Mr. J. Donaldson, Mr. R. J. Duthie, Mr. A. J. Pirie, Mr. G. Mitchell, Mr. W. G. MacDonald, and Mr. J. Mitchell.

University of Aberdeen Anatomical and Anthropological Society.

A meeting of the above society was held on Feb. 18th in Marischal College, Professor R. W. Reid being in the chair. Dr. Clark exhibited and described a pair of Distorted Feet of a female Chinese subject presented to the museum by Dr. W. R. C. Middleton, medical officer of health of Singapore. Owing to a peculiar superstition among the Chinese these specimens are very difficult to obtain and the society felt deeply indebted to Dr. Middleton for his gift. Together with the feet were shown the shoes that had been worn during life. Dr. Clark, having carefully dissected one of the feet, described in detail the soft parts and the bones. A series of excellent x ray photographs proved that the muscles were all fully developed but showed fatty degeneration of the muscular fibres and also that the individual bones were all quite normal in shape. The only difference was an alteration in the relative position of the various bones. Dr. Clark explained the method of producing the deformity and the probable reason of its being practised. Several anatomical variations which had been found in the dissecting room were also described and shown by members.

Death of Dr. James Alexander Innes.

Dr. James Alexander Innes, for about 40 years a medical practitioner in Dufftown, died on Feb. 14th after a short illness. The deceased was a native of the district, his father, the late Mr. John Innes, being a farmer in Auchindoun. Dr. Innes had a large practice in the neighbourhood and was also consulted by many people from the adjoining shires. About 25 years ago a large sum of money was collected in the district to present him with a testimonial, but when the movement was brought to his notice he requested that the money should be returned to the donors, stating that many had contributed who required the money themselves. He read and studied much and always kept up to date in regard to his professional work. Dr. Innes was in his sixty-sixth year and had continued in practice until a few months ago.

Honours to Scottish Practitioners in Spain.

Dr. W. A. Mackay and Dr. Ian Macdonald, both of whom practise in Huelva, Andalusia, Spain, have been elected honorary members of the Academy of Medicine and Surgery of Seville and the latter in an open concours has been awarded the prize of the Academy of Medicine and Surgery of Saragossa for an essay on Gastro-enterostomy, the clinical material being furnished by the Huelva Hospital and the clinic of Dr. Mackay and Dr. Macdonald.

Feb 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Royal College of Surgeons in Ireland.

THE annual Charter dinner of the Royal College of Surgeons in Ireland has now been fixed to take place on Saturday, Feb. 25th. Owing to this fact the Leinster branch of the British Medical Association has issued a circular to its members stating that it has been deemed necessary to abandon, at all events for the present, the branch annual dinner. The business of the annual meeting of the association will be transacted on Feb. 25th at the Royal College of Physicians of Ireland, Kildare-street, Dublin.

A Public Health Museum

At a meeting of the Medical Faculty of the Catholic University School of Medicine held on Feb. 16th the following motion was carried unanimously:—

> That this faculty is of opinion that th[illegible]ment of a public health museum by the Department of [illegible] *Instruction of Ireland* would be of great [illegible] public as well as to many professions and trades.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Chloroform Inhaler.

AT a meeting of the Academy of Medicine held on Jan. 24th M. Reynier showed a new inhaler devised by M. Dupont and M. Thurneyssen by means of which a mixture of air and chloroform vapour in definite proportions could be obtained for the production of anæsthesia. He criticised the ordinary method in which the personal qualifications of the anæsthetist assumed undue importance and in which it was impossible to determine relative proportions of chloroform and air in the mixture inhaled under the compress. He then gave a historical outline of the various inhalers by means of which the proportion of chloroform vapour could be regulated at will; they were far safer than the above-mentioned method. He had examined the inhalers of Paul Bert, Raphael Dubois, and others. He disapproved of the patterns which contained valves, for valves were liable to derangement and, as the experiments of Richet and Langlois have shown, the force of the breath in expiration was not always sufficient to make them act properly. The inhaler of M. Dupont and M. Thurneyssen had no valves; it consisted essentially of a horizontal tube conveying air and having a vertical tube containing chloroform connected to it at right angles. Air drawn through the first tube carried with it chloroform vapour the proportion of which might be adjusted by a graduated regulator. It has been found practically that the expired air, loaded with water vapour, could not make its way into the chloroform tube. The inhaler was provided with a thermometer which served an important purpose, for the proportion of chloroform vapour rose rapidly with a rise of temperature. M. Reynier has made practical use of the inhaler 125 times for the performance of surgical operations varying from gastro-enterostomy to simple curettage. He was impressed by the facility with which the patients became unconscious without struggling and almost without vomiting. M. Reynier recommended the general adoption of this inhaler which was very simple, was not expensive, and gave the surgeon complete security. At the meeting of the Academy held on Jan. 31st the topic was resumed by M. Lucas-Championnière whose opinions differed in many respects from those of M. Reynier. He said that physiological experiments on dogs, a method on which M. Reynier relied, gave results which were not strictly applicable to the human subject. Paul Bert had determined limits within which the chloroforming of dogs was practicable but for the human subject these limits could not be defined because no one would venture to expose a fellow creature to the risks of an experiment pushed to the point of danger. In recorded fatal cases the doses were often very small. It was necessary to pay great attention to the susceptibility of the individual patient and for that reason a competent anæsthetist who supplied drops according to the requirements of the moment would always be preferable to inhalers, even the most perfect, all of which required to be managed by a competent person. In a general way M. Lucas-Championnière distrusted inhalers which worked at constant pressure. Not even the purest samples of chloroform always yielded the same quantity of vapour at the same temperature. Nothing was therefore, in his opinion, equal to the intelligent control of an experienced anæsthetist, for the human factor, although in some respects an unquestionable source of danger, was, on the whole, the best guarantee of safety. If absolutely compelled to use an inhaler he would give the preference to the one
oxygen and chloroform vapour
of M. Roth and M. Guglielminett
could be constantly and easily controlled by the operator. Since it has been employed in the hospitals it has always answered perfectly, so far as M. Lucas-Championnière has seen. Insensibility was produced readily, and without struggling and was maintained with a very small quantity of chloroform; recovery was easy and owing to the presence of undiluted oxygen this stage was soon completed. There were few, if any, troublesome after-effects of the inhalation. M. Reynier replied that the arguments of M. Lucas-Championnière could not alter the facts and that facts had demonstrated that the inhaler which he had described was not only free from danger but possessed other advantages as well. The human factor was a source of great danger; expert anæsthetists might extricate themselves from difficult positions but almost all fatalities were due to the unskilfulness of the anæsthetist. It was quite true that all samples of chloroform did not give the same quantity of vapour at the same temperature, but M. Reynier took as his standard of comparison the chloroform used in the hospitals which was of uniform quality. With respect to the inhaler of Roth
anc
an
adc
not without risk of producing pulmonary congestion. To these observations M. Lucas-Championnière replied that *oxygen was not dangerous in this respect and that in the hospitals it was given every day to patients* suffering from asystole, a condition which increased the liability of a person to congestion.

A New Surgical Knot.

At a recent meeting of the Société de l'Internat des Hôpitaux de Paris M. Dartigues showed a new double knot for securing vascular pedicles. Passing a ligature under the pedicle he tied it tightly and then without cutting the ends he passed them again under the pedicle at a distance of a centimetre from the previous constriction and finally tied them together. In this way the pedicle was secured by two circular ligatures a centimetre apart and also by the lateral parts passing obliquely between them.

Microbicidal Action of Magnesium.

At a recent meeting of the Academy of Sciences M. F. Diénert stated that on adding metallic magnesium to cultures of the bacillus coli communis and Eberth's bacillus he had found that all the organisms died after two or three days. The addition of magnesia to the cultures did not kill the organisms but only retarded their development. The organisms were, however, killed in two or three days by magnesia in presence of hydrogen, which acted by removing the oxygen.

Gigantism and Goitre.

At a recent meeting of the Neurological Society M. G. Ballet reported the case of a young woman, aged 19 years, who was manifestly the subject of gigantism but who in addition showed all the classical symptoms of exophthalmic goitre. The hypothesis of connecting the relation which exists between gigantism and exophthalmic goitre to hyperthyroidisation is a natural one in this case. It is well known that ablation of the thyroid body with consequent hypothyroidisation brings about arrest of the development of the skeleton and it is therefore rational to suppose that hyperthyroidisation would produce the opposite effect. But in that case the association of gigantism with exophthalmic goitre should be frequent at least in young subjects, which, however, is not the case. It would be more logical to suppose in the case cited by M. Ballet that there coexisted a double lesion of the thyroid body and of the pituitary body.

Poisoning by Violet Ink.

M. Halle recently reported to the Pediatric Society, a case in which an infant, aged 16 months, had swallowed about one cubic centimetre of the violet aniline ink which is in common use. One hour after swallowing the ink the mother made the child vomit several times by putting her finger down the throat. The vomited matter was not coloured but it contained some black powder similar to that which is seen at the bottom of a dried-up inkpot. Some hours later the child had shivering, vomiting, and a raised temperature which mounted rapidly to 39° C. There were also facies abdominalis, choleraic diarrhœa, with very fœtid rice-water stools, and for a whole day the child's condition was very grave. On the following day the child was better but the extremities were cyanosed and œdematous. For the next few days troublesome laryngeal spasms occurred but eventually the child recovered.

Miners' Anæmia.

At a recent meeting of the Academy of Medicine M. Brehan, medical officer of the Bethune[1] mines, read a paper upon the above-mentioned subject in which he said that although he believed that the ankylostoma duodenale was in part the cause of the condition, yet it was very rarely found in the stools of miners in the North. Of 6000 miners employed by the Bethune Company 4737 work underground and are distributed among eight shafts. Only one shaft appeared to be infected. Of 1193 miners examined by M. Brehan extremely few were found to be affected with ankylostoma, but on the other hand 603 men were found affected with [illegible] 118 with ascaris. The reason for the ra[illegible] in M. Brehan's opinion lies in the fact that mines of the North do not show underground water-soakage or stagnant pools, and finally that the temperature of the mines is generally below 23° C. In the coal basin of Liège and St. Etienne where ankylostoma is frequently found there is water-soakage and the temperature of the galleries varies from 25° to 30° C., two facts which are very favourable to the hatching of the eggs of the parasite. Prophylaxis consists in the use of boiled water, a strict medical examination of newcomers, and a refusal to employ those coming from a suspected district. Such methods, however, are a serious matter and microscopic examination of the stools would be more satisfactory than a systematic refusal of miners coming from an infected district. Such examination would be a guarantee of safety and would permit non-infected men to be employed.

---

[1] Bethune is a mining town in the department of the Pas-de-Calais not far from Arras.

Feb. 20th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

University Intelligence.

THE number of medical students at the five Swiss Universities for the winter term 1904-05 amounts to 1724. There are 958 female students enrolled in the lists and only 766 men. The number of female students goes on increasing rapidly, especially at the universities of Bern and Lausanne. The numbers stand thus :—

	Males.	Females.	Total.
Basle	123	6	129
Geneva	144	144	288
Lausanne	103	223	326
Bern	187	407	594
Zurich	209	178	387

If the increase of female students goes on at the same rate in the next five years as in the last five years the medical faculties at Bern and Lausanne will be almost monopolised by the fair sex.

Institute for Physical Therapeutics at the University of Zurich.

At a well-attended recent meeting of the Cantonal Medical Society the committee appointed at the previous meeting to consider the question of an institute for physical therapeutics[1] submitted its report. After a discussion of three hours' duration the report was agreed to with some fundamental modifications. The urgent necessity of the institute having its own out-patient department and being independent of the other cliniques was mentioned and obtained favour. The report finally agreed on is to be transmitted to the cantonal authorities, together with the expression of a hope that this institute with a capable director at its head may soon be established and that it may do valuable service both to the public and to science.

Wage Limits for Club Members at Zurich.

The "Krankenpflege" at Zürich is a very large provident society, having at the present time 6000 members. At a meeting of the medical officers held on Feb. 2nd some motions, proposed by the President, Dr. Haeberlin, caused a lively discussion. The proposal to increase the number of members by admitting persons with incomes of £60, £80, £108, £132, and £160, divided into five classes who were to pay monthly instalments of 10*d.*, 1*s.*, 1*s.* 1½*d.*, 1*s.* 3½*d.*, and 1*s.* 6*d.* per head, met with opposition from several quarters and at last an amendment, proposed by Dr. T. Zangger, was accepted limiting the right of admission to the three first classes and to persons with incomes under £120 per annum. Thus the scheme of municipalisation of medical service in Zürich, described at length in THE LANCET of Oct. 29th, 1904, p. 1246, will for the present still be limited to the working classes.

Zürich, Feb. 20th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Suez Hospital.

A NEW hospital, designed to meet the varying wants of a seaport town, was opened by the Egyptian Government last summer. It is well placed just outside the town, being surrounded by miles of desert and provided with a good view of the harbour and adjacent mountains; it is also conveniently near the Hospital for Infectious Diseases. It is of course provided with all modern requirements, electric lighting, hot-water supply, operating theatre, steriliser, laboratories, an excellent house for the English superintendent, and nursing quarters presided over by an English sister. There are separate rooms for private patients and a total of 58 beds, of which 40 were occupied at the time of my visit. Most of the patients were suffering from medical diseases, some from the malignant tertian form of malaria, which is commoner in Suez than other parts of Egypt, and there were four natives recovering from appendicitis, though this has usually been considered a rare disease in this country. The old hospital in the town is still utilised for out-patients and for the treatment of prostitutes.

Neurasthenia.

This complaint is rare among the natives of this country, who are not given to nervous strain, but cases are met with among the Red Sea lighthouse-keepers who are mostly Englishmen. They suffer from sleeplessness, emotional symptoms, tremors, and exaggerated reflexes which the men themselves put down to their lonely life and the monotony of their existence and their food. The tinned food causes dyspepsia and consequent loss of weight but not scurvy. There are always three men in each lighthouse, while the fourth is absent on leave, and they are only visited every three months when they get letters and newspapers. Two men lately committed suicide after leaving Egypt and a third developed delusions.

Sleeping Sickness.

Captain E. D. W. Greig, I.M.S., was one of those sent by the Royal Society with Colonel Bruce, R.A.M.C., and Dr. D. N. Nabarro, in 1903 to Uganda and as he is now passing through Cairo on his way to London he very kindly consented to deliver a lecture on Sleeping Sickness at the Medical School. About 100 interested people besides the students attended the lecture which was delivered in the Pathological Museum and was illustrated by maps, temperature charts from man and monkey, and beautiful diagrams of the tsetse fly and the trypanosome prepared by Dr. Looss. Only 100 years ago the disease was first described as a separate complaint and until 1901 it was thought to be confined to West Africa between the Congo and the Senegal and its cause was shrouded in mystery. Its introduction into Uganda can be accounted for by the opening up of trade routes from West Africa. The total loss from this cause since 1901 in the Uganda Protectorate is 100,000 and the monthly death-rate is still at least 1000, so that if sleeping sickness continues unchecked the whole population will shortly cease to exist. The disease is limited almost entirely to the northern shores of the Victoria Nyanza Lake and to the various islands in the lake. Two maps, exhibiting the distribution of the disease and the prevalence of the glossina palpalis, showed the exact co-incidence of the tsetse fly and the endemic. Fortunately imported cases in inland villages do not cause spread from man to man but the disease in the endemic area has already destroyed all the natives of some districts. Captain Greig insists that the name of the disease is misleading, because sleepiness only occurs in the latest stage which may last three or four months; this may be replaced by mania and morbid elevation of the mental powers. The most important early sign of the disease is enlargement of lymphatic glands, especially those of the cervical region. This has been known for years to the slave dealers who in the old days refused to let a slave with these glands enlarged join the caravan because he was almost certain to die on the journey. Captain Greig has discovered that by puncturing the cervical glands with an ordinary syringe trypanosomes can be seen under the microscope long before the fever and other symptoms occur. He calculates that about 70 per cent. of the general population of areas in which sleeping sickness is endemic are in this early stage which may terminate in one of three ways: (1) by extension of the trypanosome to the lymph spaces of the brain and the spinal cord, constituting sleeping sickness proper; (2) by death from intercurrent disease, of which the most common is pneumonia; and (3) by the disease becoming very chronic and possibly ending in recovery. With regard to this last point the lecturer told me that there are several cases of individuals still alive who certainly had the disease in 1902 and 1903. There is therefore a probability that many of the inhabitants may become immune or "salted," as is the case in many diseases of animals. So long as the trypanosome is confined to the lymphatic glands the temperature is normal and there are no obvious symptoms except the glandular swellings. But when the parasite gets into the blood irregular fever begins, varying from 100° to 103° F., emaciation and nervous tremors are seen, till in the final stage the temperature gradually sinks till it remains for days as low as 92°, when the trypanosome has invaded the brain and the spinal cord and set up a *meningo-myelitis*. It is now proved that the trypanosome exists in every case of sleeping sickness and it is a near relation of the parasite which causes surra or nagana in cattle. Inoculation of monkeys with the blood and cerebro-spinal fluid of patients suffering from sleeping sickness produces the same disease in these animals. One fact new to most of the audience is that the glossina palpalis belongs to the pupipara group of insects which produce one larva instead of myriads of eggs. The fly by means of its long proboscis can fill its stomach by sucking infected blood for half a minute and is then ready charged at any time during the next five days to infect any healthy person. Experiments on monkeys lead to the belief that it is not dangerous after five days have elapsed. The fly is most active during the day, which is, of course, the time when the natives are working in the fly belts. The fly seems to require for its life forests of trees granting shade and dense undergrowth in proximity to water. These conditions invariably exist in areas where sleeping sickness and glossina palpalis prevail but as one descends the Nile it is found that 30 miles north of Gondokoro the character of the country changes; there are large open spaces without much undergrowth and the tsetse fly is absent. It is therefore probable that sleeping sickness will not spread to the Sudan and Egypt, though the forest conditions of the Bahr-el-Gazzal are said to be quite favourable to the habits of this special tsetse fly. South of the Victoria Nyanza the country again changes to open ground and this fly is absent. A synopsis distributed to the audience enabled them more easily to understand the lecture.

Cairo, Feb. 5th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Bubonic Plague.

AN outbreak of bubonic plague has occurred in the Grafton district, New South Wales. The deaths of five persons are stated to have been due to the disease. Rats have been dying in large numbers on the farms where the affected persons lived but plague was not suspected at first. These farms have now been quarantined and a staff, consisting of a medical officer, a sanitary inspector, and a rat-catcher, has gone to Grafton. The last previous evidence of plague was on Dec. 3rd, 1904, when a plague-infected mouse was found in Sydney.

Preservatives in Milk.

The question of the use of preservatives in milk continues to be disputed in the law courts and to occasion differences of expert evidence. On Dec. 22nd, 1904, the *Bacchus Marsh Concentrated Milk Company was prosecuted for selling* concentrated milk containing 219 grains of boric acid to the gallon. Dr. W. P. Norris, medical inspector to the Board of Health of Victoria, said that the amount of boric acid in the sample was unnecessary and harmful and in great excess of the amount said to be necessary by the advocates of the use of preservatives in milk. In his opinion refrigeration would keep the milk as long as the Bacchus Marsh Company said its milk should be kept. For the defence Dr. J. W. Springthorpe, lecturer on hygiene at the University of Melbourne, said that he had used boric acid in doses of 30 grains per day in over 300 cases of typhoid fever, also in epilepsy and other diseases, and had never seen any injurious effects. It would be impossible to keep concentrated milk more than a day without preservatives. He considered that stale sterilised milk was worse than milk with preservatives. Mr. A. H. Jackson, B.Sc., president of the Institute of Analysts, said that preservatives were not injurious when used in the manner *stated in the case in dispute*. The bench fined the defendant company and said that the law did not recognise the use of preservatives.

Treatment of Inebriates in New South Wales.

Some two years ago the New South Wales Parliament passed an Inebriates Act under the provisions of which the Government sanctioned the erection of two State institutions for the treatment of inebriates without means. One of these for females, situated on Rabbit Island on the Hawkesbury river, has been partly erected and will accommodate 72 patients. It consists of two pavilions for sleeping accommodation, dining room, kitchen, laundry, workroom, reception house, officers' quarters, and matron's cottage. An abundant supply of good water has been obtained. The institution was inspected recently by the Minister of Works who will probably advise the Cabinet to utilise the buildings early in the year.

Hospital Affairs.

The Kronheimer wing at the Austin Hospital, Melbourne, still remains unopened owing to the action of the Premier. At a recent meeting of the executive committee of the Society for the Prevention of Tuberculosis it was decided to bring the matter officially under the notice of the respective medical societies with the view of inducing them to take united action to secure the withdrawal of the opposition of the Premier.—Some feeling has been roused by the refusal of the directors of the Sydney Hospital to appoint a woman as resident medical officer. It has been customary annually to appoint six members of the resident staff of the Sydney Hospital and the Royal Prince Alfred Hospital from the best students who have just passed their final examinations at the University of Sydney. Among *these at the last election was Miss Susie O'Reilly*. The selection is usually made by a conjoint board consisting of the presidents and professional delegates from the hospitals concerned. On this occasion, however, the board selected six men for the Prince Alfred Hospital and five men for the Sydney Hospital and left the sixth appointment an open question for the directors of the latter institution. This body decided not to appoint Miss O'Reilly but a male graduate.—The fourth annual meeting of the Sydney Medical Mission was held recently. The medical report showed that 3216 visits were paid to the homes of 720 patients and that the total number of patients treated was 2256.

The Board of Public Health of Victoria.

The Government has appointed Dr. William P. Norris to the position of chairman and chief medical inspector of the Board of Public Health of Victoria, rendered vacant by the [illegible] native of [illegible] Melbourne, [illegible] B. in 1888 and M.D. in 1892. After some years in private practice he went to England and [illegible] diploma in public healt[illegible] the appointment of ass[illegible] of Health, which he has [illegible]

The Death-rate of Sydney.

The death-rate of the city of Sydney during the first 11 months of 1904 equalled 12 per 1000 of the population, being the lowest experienced in the city during the past seven years at least. *Calculated on the number of births* the infantile mortality rate for the first 11 months of 1904 was equal to 118 deaths per 1000.

Instruction in Dentistry at the University of Sydney.

[illegible] ty of Sydney at its last monthly [illegible] curriculum for the department [illegible] ie degree of Bachelor of Dental Surgery. [illegible] of the University Dental Hospital and the Sydney Dental Hospital is now satisfactorily completed and working well.

Jan. 10th.

VACANT CHAIRS AT THE UNIVERSITY OF KAZAN.—There are, *says the Meditr. Obosrenie, seven* vacant chairs in the University of Kazan: anatomy, operative surgery, psychiatry, diagnosis, special pathology, therapeutics, and forensic medicine and pharmacy.

Obituary.

ROBERT STEVENSON THOMSON, M.D., D.Sc. Glasg., F.F.P.S. Glasg.

By the death of Dr. R. S. Thomson, professor of the practice of medicine in Anderson's College Medical School, Glasgow has lost one of its most distinguished and respected members of the profession as well as one of the most successful of extra-mural teachers. Dr. Thomson became seriously ill at the beginning of September last but after two or three weeks of great anxiety on the part of his friends he rallied and hopes were entertained of his ultimate recovery. These hopes were to some extent confirmed by his progress up to the new year and for a short time afterwards but a more serious phase of his illness set in about a month ago which brought about the fatal termination. Dr. Thomson was born in Southampton 47 years ago. He spent his earlier years in St. Petersburg, his father being an engineer in that city. He received his education, however, in Glasgow, attending first the Glasgow Academy and subsequently the University of Glasgow. He devoted himself to science as well as medicine, taking the degree of B.Sc. in 1880 and those of M.B., C.M. in 1882. Subsequently he was resident physician in the Western Infirmary under Dr. J. Finlayson; later he held a similar position in Belvidere Fever Hospital and then proceeded to Vienna to supplement his studies there.

For the last 21 years he has been in medical practice in Glasgow but much of his time was devoted to hospital work and to teaching. Among the more important of the various appointments which he has held were those of dispensary physician and then assistant physician to the Western Infirmary, clinical assistant to Dr. Finlayson at the same institution, extra-honorary physician to the Royal Hospital for Sick Children, visiting physician in charge of the Small-pox Hospital, Belvidere, and professor of medicine at Anderson's College Medical School. The latter position he has held since 1899; his success there was immediate, the students numbering last year 120. He has contributed largely to medical literature, chiefly of late in connexion with small-pox and vaccination. He received the degree of M.D. with honours in 1897 and the degree of D.Sc. in 1901. His death will be mourned alike by his friends, the medical profession generally of Glasgow, by whom he was held in high esteem, and by his numerous students past and present. Much sympathy is felt for his widow and relatives.

WILLIAM COBDEN ROWLANDS, M.B., C.M. Edin.

Dr. William Cobden Rowlands died on Jan. 19th at his residence, Maesteg, Glamorganshire, from pneumonia and pleurisy following an attack of influenza. He was the eldest son of Principal Rowlands of the Memorial College, Brecon, and took part of his medical curriculum at University College, Cardiff, where he was president of the debating society of the college and captain of the cricket eleven. He then proceeded to the University of Edinburgh, where he graduated as M.B. and C.M. with honours in 1897. He was president of the University of Edinburgh Welsh Students' Union and a member of the students' representative council. On becoming qualified he held an appointment as assistant at Aberaman and in 1897 went to Maesteg, where two years later, on the retirement of Dr. John Davies, he took over that gentleman's practice in conjunction with Dr. John Harris Jones. The deceased, who was only 39 years of age, by his kind and gentle manners endeared himself to the hearts of his numerous patients and the news of his early death came as a sad blow to them all. He has left a widow and a little girl. The funeral, which was attended by a very large number of sympathetic friends and representatives of various public bodies, took place at Brecon on Jan. 23rd.

SAMUEL HOLLINGSWORTH AGAR, L.R.C.P. Irel., L.R.C.S. Irel.

The death of Mr. Samuel Hollingsworth Agar at his residence at Henley-in-Arden, Birmingham, on Feb. 11th, has removed a familiar and useful member of the profession from the Midland counties, in which he was well known and much respected. Mr. Agar was in his seventy-fourth year. He was a native of county Wicklow and after taking the Licence of the Royal College of Surgeons in Ireland went to Henley-in-Arden in 1854. After a time he gave up general practice and devoted his attention to the care of the insane. He became proprietor of a large private asylum—Glendossill, Henley-in-Arden—and his conduct of this establishment and his care and attention to the patients obtained him a wide reputation and caused his opinions to be valued highly. Mr. Agar was a man of much public spirit and was practically impressed with the obligations of civic and political duties. He was a valuable member of the Warwickshire county council and also a justice of the peace for the county. At one time he was president of the Birmingham branch of the British Medical Association, his genial manners and suave address gaining him many friends. Mr. Agar gathered round him a wide circle of friends who became endeared to him through his many virtues. With his deep sympathies, warm heart, and ready help he became a recognised and valued power in the locality in which his life's work was done and his death is much deplored. He was buried at Beaudesert Church, Henley-in-Arden, on Feb. 16th, amid many manifestations of regret. Mr. Agar leaves two sons, one of whom is a member of the medical profession.

Medical News.

University of London.—At the Preliminary Scientific Examination for internal and external students held in January the following candidates were successful:—

Inorganic Chemistry, Experimental Physics, and Biology.—John Leo Atkinson, Guy's Hospital; Ardeshir Pestonji Bacha, University Tutorial College; Bertie Blackwood, University of Leeds; Karl Bremer, St. Bartholomew's Hospital, Cornell University, and Victoria College, South Africa; William Gidley Emmett, Nottingham High School; Edith Croft Goodison, London (Royal Free Hospital) School of Medicine for [illegible] ynes Lovell, St. Mary's Hospital an [illegible] lege; Arthur Griffith William Owen, [illegible] and University of Liverpool; and Edw[illegible] mas's Hospital.

UNIVERSITY OF CAMBRIDGE.—The Huddersfield lectureship in special pathology is vacant. Applications are to be made to the Vice-Chancellor by March 7th.—The degree of Doctor of Science, *honoris causâ*, is to be conferred on Dr. E. B. Tylor, professor of anthropology in the University of Oxford.—Professor D. J. Cunningham of Edinburgh has been appointed an elector to the chair of Anatomy, Dr. J. Mitchell Bruce an elector to the Downing chair of Medicine, Professor T. Clifford Allbutt an elector to the chair of Surgery, and Dr. D. MacAlister an elector to the chair of Pathology.—The following degrees were conferred on Feb. 16th :—

St. John's;

larvey, St.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in February the following candidates passed in the subjects indicated :—

Surgery.—H. H. R. Bayley (Section II.), Charing Cross Hospital, A. Feeley (Section I.), Leeds; J. A. Davies (Section I.), Manchester; L. Sells (Section I.), St. Thomas's Hospital; R. W. Taylor (Sections

and
ulley
rge's
, St.
A. R.
P. N.
and

J. H. Wolfe, London Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—H. H. R. Bayley, R. W. Taylor, and J. H. Wolfe.

TRINITY COLLEGE, DUBLIN.—At examinations held in Hilary term the following candidates were successful :—

FINAL IN MIDWIFERY.

Robert Magill, Michael J. M'Auliffe, George E. Nesbitt, Cecil Scaife, Edward G. Scroope, John A. Pringle, John W. Burns, Joseph W. Houston, Richard Kelly, and Robert A. Askins.

THE AMBIDEXTRAL CULTURE SOCIETY.—The opening lecture of this society for the session 1905 was delivered at the Guildhall School of Music, Thames Embankment, E.C., by Professor W. H. Cummings, Mus.D., on Feb. 15th, his subject being Ambidexterity in Music. The second, third, and fourth lectures of the series will be delivered at the rooms of the Royal Statistical Society, *Adelphi-terrace, Strand, London, W.C.* On *March 2nd*, at 8.15 P.M., Sir James Sawyer will take for his subject Ambidexterity from some Points of View of a Physician; on March 16th, at 8 P.M., Sir W. B. Richmond, K.C.B., will deal with Ambidexterity in Art; and on April 13th, at 5 P.M., Mr. E. Noble Smith will discourse on Ambidexterity in Surgery.

THE EDUCATION AND TRAINING OF NURSES.—A meeting convened by the Matrons' Council of Great Britain and Ireland and the Society for the State Registration of Trained Nurses was held at 20, Hanover-square on Feb. 22nd to protest against the terms of the memorandum of association of the Incorporated Society for Promoting the Higher Education and Training of Nurses. Lady Helen Munro Ferguson presided and there was
motions were unanimously
the protest for which the
; that "no powers can be
except by a body composed
of professional persons upon which trained nurses have direct and sufficient representation"; the second supporting the Bill for the registration of trained nurses introduced into the House of Commons by Mr. Munro Ferguson, M.P.; and the third stating that a deputation should be sent to the Board of Trade to present to the president of that body the first two resolutions.

THE QUEEN'S JUBILEE HOSPITAL.—We have been requested to publish the following resolutions which were put forward and agreed to at a meeting of members of the medical staff which was held on Feb. 6th :—

1.
the

C. N. BARTON, M.R.C.S.

LADS' DRILL ASSOCIATION.—The annual report of the Lads' Drill Association shows that continuous and steady progress has been made during the year 1904 in the systematic physical and military training of British lads. Conscription is an unpopular word and the system which it denotes is hardly likely to be tolerated by this country except under dire necessity. It is nevertheless desirable that every Englishman should be able to handle a rifle effectively should he be called upon to defend his country. The training necessary to produce this result is one of the objects of this association and it is therefore one deserving of support. To train youths to arms during the educative period of their lives would probably have a useful moral effect upon the hooligan and loafing element of the population, always, of course, provided that the lads were properly fed. Lord Meath is the chairman of the association and the secretary is Colonel W. Elliott, whose address is 44, Harrington-gardens, London, S.W.

A lecture will be delivered to-day (Saturday, Feb. 25th), at 3 P.M., by Sir William J. Collins, chairman of the education committee, London County Council, on "The Man *v.* the Microbe," in the Marlborough Room at the Polytechnic Institute. Dr. Allan Macfadyen will occupy the chair.

University College Hospital.—At a meeting held on Feb. 14th of Sir Donald Currie's Donation Committee Mr. Paul Waterhouse was appointed architect for the erection of the school of advanced medical studies, students' house, and the nurses' home in connexion with University College Hospital.

Exeter Dispensary.—The annual meeting of the subscribers to the Exeter Dispensary was held on Feb. 15th. The report stated that 5329 patients had been treated during 1904, as compared with 5440 in 1903. The financial statement showed that the total expenditure for the year was £1699 and that an adverse balance of £72 remained.

Donations and Bequests.—By the will of Mrs. Mary Worthington of Sale, Chester, vice-president of the Union of Manchester University Women Students, a sum of £1000 is bequeathed to the Owens College, Manchester, and a like sum to the Manchester and Salford Sick Poor and Private Nursing Institution.—The late Miss Ellen Peel of Dorking bequeathed £500 to Dorking Cottage Hospital and the same amount to Tamworth Cottage Hospital.—Under the will of Mr. Augustus George Hubbuck of Rotherfield, Sussex, the East London Hospital for Women and Dispensary at Shadwell receives £2000, and the Chelsea Hospital for Women £1000.

The Association for Promoting the Training and Supply of Midwives.—The annual meeting of this association was held at Caxton Hall, Westminster, S.W., on Feb. 14th, under the chairmanship of Mr. H. Cosmo Bonsor. One of the main objects of the association as stated in the report, which was unanimously adopted, "is to become a centre or bureau of information for the public, relative to the requirements of the Midwives Act, and its working all over the country." The council hopes that the education committee of the London County Council will include lectures to midwives in its technical courses, provided audiences can be insured, and with this object in view the various districts of London are being canvassed by the association. The preliminary result of this canvass points to a successful result. The financial committee appeals for help to defray the liabilities of the year.

Extensions at the Medical School, Newcastle-on-Tyne.—We have received plans and drawings showing the proposed extensions at the present Medical School at Newcastle-on-Tyne. The new wing, which will extend along the west side of the present building, will be 119 feet in length, with a caretaker's house at the south end. The whole of the ground floor is given up for the use of the students and will contain a gymnasium, 40 feet by 30 feet by 18 feet high, with bath-room, lockers, &c., attached to the same; also reading, dining, and smoking rooms, kitchen, larders, &c. The first floor will contain a laboratory, 40 feet by 30 feet; histology room, 40 feet by 30 feet, with research and professors' rooms attached to same; also a dark and optical room. On the second floor there will be a lecture theatre, 40 feet by 30 feet by 16 feet high, to accommodate 100 students, a bacteriological room, 40 feet by 30 feet, with research room, professors' private rooms, and a dark and optical room. The new wing has been designed to harmonise with the present building and will be built of bricks, stone sills and mullions, and terra-cotta strings and cornices, and the roof will be covered with green Westmorland slates. Special attention has been paid with regard to the light required for the microscopical work. The windows in the bacteriological and histology rooms contain no transoms or mullions. All the floors will be fireproof and the surface will be finished with granolithic cement. A newellite dado, four feet six inches high, will go round the bacteriological and histology rooms, and the laboratory, and the walls will be finished with adamant and ripolin. All the corners will be rounded, so that there will be no crevices for dust or dirt to lodge and the doors will be flush-panelled on the inside. The building will be lighted throughout by electricity and will be heated on the hot-water low-pressure system and will be ventilated by extraction flues with electric fan in the roof. The building has been designed by the firm of Messrs. Dunn, Hansom, and Fenwicke, architects, 23, Eldon-square, Newcastle-on-Tyne.

Weston-super-Mare Hospital.—At the annual meeting of the subscribers to this institution held on Feb. 17th it was reported that 436 patients had been treated during 1904, an increase of 106 as compared with the previous year. The daily average number of in-patients was 26·5. The financial statement showed that a favourable balance of £101 remained.

Association of Medical Diplomates of Scotland.—The inaugural dinner of the Association of Medical Diplomates of Scotland was held at the Trocadéro Restaurant, London, on Feb. 14th, Mr. C. St. Aubyn-Farrer being in the chair. After the usual loyal toasts had been duly honoured Mr. E. Noble Smith proposed the toast of "The Navy, Army, and Auxiliary Forces." Sir J. A. Clark, in replying, urged upon the members of the medical profession the duty of preparing for the time of war so that should the necessity arise they could render efficient help more quickly than was the case in the South African war. This toast was also replied to by Colonel J. Anderson, I.M.S., and Brigade-Surgeon-Lieutenant-Colonel E. J. Hunter. Mr. St. Aubyn-Farrer then proposed the toast of "The Association of the Medical Diplomates of Scotland" and gave a glowing account of the progress and success of the association. He was himself attired in the new gown granted by the Royal College of Surgeons of Edinburgh to its Licentiates. This gown was the first tangible result of the labours of the association. Dr. Euphemia Stoker replied and was followed by Dr. David Walsh, the secretary of the association, who announced that at the end of December, 1904, 124 members had been elected and up to the present date 14 more, making a total of 138 members. This included 48 London and 90 provincial members. The association included amongst its ranks six lady members. Dr. H. W. Fitzgerald Powell proposed "The Visitors" which was acknowledged by Dr. E. A. Snape and Dr. F. J. Waldo. Dr. C. O. Hawthorne proposed the toast of "The Council and Officers of the Association" which was suitably replied to by Mr. S. Stephenson.

Central Midwives Board.—The members of the Central Midwives Board met on Feb. 16th at 6, Suffolk-street, Pall-mall, Dr. F. H. Champneys being in the chair. The Board considered the subject of the recognition of Poor-law infirmaries as training schools for midwives. Miss J. Wilson said that the Local Government Board some years ago, when Sir Walter Foster was Parliamentary Secretary to the Local Government Board, issued a circular letter to boards of guardians stating that the Local Govenment Board did not recognise midwives in Poor-law infirmaries but considered them as midwifery nurses. Miss Wilson suggested that the Central Midwives Board should apply to the Local Government Board for copies of all circulars that it had issued dealing with midwifery nurses or midwives. Mr. E. Parker Young pointed out that the Local Government Board knew the rules of the Central Midwives Board and was aware that the Central Midwives Board had to carry out the Midwives Act and was not bound by the circulars issued by the Local Government Board. After Mr. Young had fully stated his views Miss Wilson withdrew her suggestion. The Central Midwives Board then decided that no Poor-law infirmary should be approved as a training school for midwives unless the average number of births reached not less than 75 per annum—i.e., sufficient to insure the necessary number of cases for the training of at least three pupils. It was also agreed that no application from a Poor-law institution to be approved as a training school for midwives should be entertained unless it was in the form of an official communication from the board of guardians concerned, signed by the clerk of the board.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Private Members' Bills.

A LARGE number of private Members' Bills now appear on the order paper of the House of Commons. Those Members who had hoped to secure good places in the first ballot for Bills more or less directly affecting the public health have been disappointed. All the good places for early days have been secured by other would-be legislators and consequently the prospects of obtaining a serious and adequate discussion of the pharmacy and other kindred measures, of which notice has been given, are not particularly bright.

Amendment of the Pharmacy Acts.

In the course of the session the Government may legislate upon the recommendations of the committee on the sale of poisons. It was expected that it would do so last session, but apparently, whatever be the intentions of Ministers, the efforts of private Members to secure some reform will not be relaxed. Mr. THOMAS LOUGH has already brought in a Bill "to provide for the further regulation of the sale of poisons and the compounding of medical prescriptions and to amend the Pharmacy Acts, 1852 and 1886." The Bill has the support of Sir MANCHERJEE BHOWNAGGREE, Mr. HENNIKER HEATON, Mr. CROOKS, Mr. OSMOND WILLIAMS, Mr. ELLIS GRIFFITHS, Mr. JAMES REID, Mr. MUNRO-FERGUSON, Mr. MARSHALL HALL, Mr. REMNANT, and Mr. ERNEST GRAY—a group of Members drawn from both sides. The second reading has been put down provisionally for March 24th.

Municipal Milk Depôts.

The agitation for a greater control over the milk-supply of London has led to the introduction of a Bill to allow metropolitan borough councils to establish and to maintain milk depôts. Mr. THOMAS LOUGH is again the sponsor. Associated with him are Dr. J. G. SHIPMAN, Sir CHARLES DILKE, Mr. WHITELEY, and Dr. MACNAMARA.

Juvenile Smoking.

Apparently the crusade against juvenile smoking is still being carried on with some vigour. Since Parliament opened a number of petitions have been lodged praying for legislation on the subject.

A Public Health Bill.

On March 1st Sir ALFRED HICKMAN will present a Bill to amend the Public Health Acts.

Medical Act (1886) Amendment Bill.

General LAURIE has again brought forward his Bill to amend the Medical Act of 1886. It deals with the position of colonial practitioners coming to this country. He has the support of Sir WALTER FOSTER, Sir JOHN BATTY TUKE, Mr. ROTHSCHILD, Sir HOWARD VINCENT, Mr. MIDDLEMORE, and Sir MANCHERJEE BHOWNAGGREE.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BLETSOE, J. H., M.B., B.S. Lond., has been appointed House Surgeon to Out-patients at St. Thomas's Hospital.

BRADFORD, A. B., M.B., B.S. Durh., has been appointed Senior Ophthalmic House Surgeon at St. Thomas's Hospital.

BRODRIBB, F. A., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

CARPMAEL, N., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed to the Skin Department at St. Thomas's Hospital.

CARVER, N. C., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.

CHAPMAN, WALTER, M.B., B.Ch. Birm., L.R.C.P. Lond., M.R.C.S., has been appointed Public Vaccinator for the Fourth District of the Totnes (Devon) Union.

COOK, HERBERT G. G., M.D. Lond., F.R.C.S. Eng., D.P.H. Camb., has been appointed Medical Officer to H.M. Prison at Cardiff.

COUTTS, D. K., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to Out-patients at St. Thomas's Hospital.

DEAN, H. R., M.B., B.Ch. Oxon., has been appointed House Physician to Out-patients at St. Thomas's Hospital.

DOUGLAS-CRAWFORD, DOUGLAS, M.B. Edin., F.R.C.S. Eng., has been appointed Honorary Consulting Surgeon to the Liverpool Dental Hospital.

DREW, J. H., M.R.C.S., L.R.C.P. Lond., has been appointed to the Ear Department at St. Thomas's Hospital.

EVANS, H. W., M.R.C.S. Eng., L.R.C.P. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Littleport District of the county of Cambridge.

FOOTNER, G. R., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.

FOWLER, F., M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed to the Electrical Department at St. Thomas's Hospital.

GIBSON, A. G., M.B., B.Ch. Oxon., B.Sc. Lond., has been appointed Resident House Physician at St. Thomas's Hospital.

GRAY, R. E. G., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.

HAWARD, W., M.B., B.S. Durh., has been appointed to the Skin Department at St. Thomas's Hospital.

HAWES, G. C. B., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Pangbourne and Whitchurch District of the counties of Berks and Oxford.

[illegible] R.C.P. Lond., has been appointed to [illegible] Thomas's Hospital.

[illegible], has been appointed House Physician [illegible] s's Hospital.

KENT, PERCY WHEELER, M.R.C.S., L.R.C.P., D.P.H. Camb., has been [illegible] County Police at Barry.

KIS[illegible] has been appointed Resident [illegible] tal.

KNA[illegible], L.R.C.P. Lond., has been [illegible] Surgeon to the Huddersfield Infirmary.

LANGLEY, G. J., M.B., B.S. Lond., has been appointed to the Throat Department at St. Thomas's Hospital.

MILLS, F. A., M.B., B.C. Cantab., has been appointed Assistant Anæsthetist to the Royal National Orthopædic Hospital.

MILSOME, H. B., M.D. St. And., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Chertsey District of the county of Surrey.

[illegible] L.R.C.P. Lond., has been appointed to the [illegible] Thomas's Hospital.

[illegible] R.C.S., L.R.C.P. Lond., has been appointed [illegible]-patients at St. Thomas's Hospital.

[illegible] has been appointed Senior [illegible] mas's Hospital.

[illegible], D.P.H. Camb., has been [illegible] of Guildford.

POPE, GEORGE STEV[illegible] P.S. Glasg., has been appointed M[illegible] nerset and Bath Asylum, Wells.

TAKAKI, K., M.R.C.S., L.R.C.P., has been appointed Resident House [illegible] Hospital.

[illegible] R.C.P., has been appointed to the X-ray [illegible]'s Hospital.

THOMPSON, R. J. C., M.R.C.S., L.R.C.P. Lond., has been appointed [illegible]

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BETHNAL GREEN INFIRMARY.—Third Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

BIRKENHEAD BOROUGH HOSPITAL. — Assistant Honorary Medical Officer.

BIRKENHEAD UNION, INFIRMARY, WORKHOUSE, AND SANATORIUM.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

CARLISLE, CUMBERLAND INFIRMARY.—Resident Medical Officer Salary at rate of £80 per annum, with board, lodging, and washing.

CHELTENHAM GENERAL HOSPITAL.—Junior House Surgeon, unmarried. Salary £50 per annum, with board and lodging. Also Surgeon-in-Charge (unmarried) of Branch Dispensary. Salary £90 per annum, with board and lodging.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c. Also Pathologist. Salary 100 guineas per annum Also Two House Physicians for six months. Salary at rate of £30 per annum, with board and residence.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Assistant House Surgeon. Salary £25 per annum, with board and washing.

DURHAM COUNTY HOSPITAL.—House Surgeon. Salary £120, with board and lodging.

EAST LONDON HOSPITAL [illegible] Women, Shadwell, E.—Medica[illegible] Salary at rate of £100 per annum, [illegible] rgeon for six months. Honorarium £25, with board, residence, &c.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Physician to Out-patients Also Eight Qualified Clinical Assistants, out-patient department.

GLASGOW, ROYAL HOSPITAL FOR SICK CHILDREN.—Resident House Surgeon. Salary £50 per annum, with board and laundry.

GREENOCK INFIRMARY.—Assistant House Surgeon. Salary £40 per annum, with board and residence.

HAMPSTEAD GENERAL HOSPITAL.—Resident Medical Officer for six months, renewable. Salary at rate of £120 per annum and allowance for rooms.

KENSINGTON WORKHOUSE AND INFIRMARY, Marloes-road.—Second Assistant Resident Medical Officer. Salary £80 per annum, with apartments, board, and washing.

LICENSED VICTUALLERS' ASYLUM, Asylum-road, Old Kent road, London, S.E.—Medical Officer. Salary £200 per annum.

LINCOLN COUNTY HOSPITAL.—Senior House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant House Surgeon for six months. Salary £30, with board and lodging.

LONDON HOSPITAL, Whitechapel, E.—Assistant Surgeon.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £50 per annum, with board and residence.

MEDICAL DEPARTMENT OF THE NAVY, 18, Victoria street, London, S.W.—Three Dental Surgeons. Salary £1 per diem.

MIDDLESBROUGH, YORKSHIRE, COUNTY BOROUGH ASYLUM.—Medical Superintendent. Salary £450 per annum, with house, rates, taxes, &c.

MIDDLESEX HOSPITAL, W.—Second and Third Assistants to the Director of the Cancer Research Laboratories. Salaries £125 and £100 respectively.

MORTLACH PARISH, Dufftown, Banffshire.—Medical Officer. Salary £35 per annum and fees.

NATIONAL HOSPITAL FOR THE RELIEF AND CURE OF THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Assistant Physician for Out-patients.

NORFOLK AND NORWICH HOSPITAL.—Second Assistant House Surgeon for six months. Honorarium £20, with board, lodging, and washing.

QUEEN'S JUBILEE HOSPITAL, Earl's Court, S.W.—House Surgeon for six months, renewable. Salary at rate of £52 per annum, with board, residence, and laundry.

READING, ROYAL BERKSHIRE HOSPITAL.—Assistant House Surgeon. Salary £60 per annum, with board, lodging, and washing.

ROYAL EAR HOSPITAL, Dean-street, Soho.—Honorary Assistant Anæsthetist.

STOCKPORT INFIRMARY.—Assistant House and Visiting Surgeon. Salary £80 per annum, with board, washing, and residence.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Casualty Medical Officer. Salary £50 per annum.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancie[illegible] the Factory and Workshop Act at [illegible] Carmarthen; at Staveley, in the c[illegible] Gortin, in the county of Tyrone.

Births, Marriages, and Deaths.

BIRTHS.

GOMEZ.—On Feb. 15th, at The Cottage, South Petherton, Somerset, the wife of F. J. Gomez, M.R.C.S., L.R.C.P., of a son.

HARVEY.—On Feb. 17th, at 117a, Queen's-gate, S.W., the wife of Sidney Harvey, of a son.

KNAPP.—On Feb. 13th, at Garth, Broxbourne, Herts, the wife of Captain H. G. Knapp, I.M.S., of twins—son and daughter.

DEATH.

[illegible]-avenue, Folkestone, Lieut.-Col. [illegible] late of the R.A.M.C. and York [illegible] th year.

Notes, Short Comments, and Answers to Correspondents.

THE STERILISATION AND PRESERVATION OF FOODS BY CARBONIC ACID GAS.

[illegible] 50 years ago it was recognised that [illegible] cided antiseptic properties no serious [illegible] lse this gas for the practical purpose of preserving milk or other foods There are obvious objections to the use of certain chemical agents for preserving purposes, but to carbonic acid gas these objections in the main do not apply. Carbonic acid gas may, of course, be easily expelled if need be from the preserved food prior to consumption, while it could do the organism no harm if swallowed with the food Soda-water or water under pressure of carbonic acid gas is not poisonous nor does it have any decided physiological effect comparable with that produced by boric acid, salicylic acid, benzoic acid, fluorides, or formaldehyde The gas, however, can only be successfully employed for preserving purposes after every particle of air in the food has been displaced This is [illegible] Hemming of Kent Cottage, [illegible] a special aerating machine [illegible] a pressure of carbonic acid gas in such an effectual way as to exclude air altogether. The result in the case of milk is, according to our observation, to preserve the fluid effectually. We have, at any rate, examined *samples of milk* so treated which had been left in bottle for six weeks At the end of that time the milk showed no signs of decomposition and the fluid was perfectly uniform, no separation of curd having taken place. The taste was sweet and good and indistinguishable from that of fresh milk. Even oysters may be preserved in this way and saccharine fluids and beef juices keep well under a pressure of pure carbonic acid gas The process has the undoubted advantage that the article of food to be preserved is never in contact with metal fittings—the aeration is, in fact, effected in the bottle In this way the method of aeration differs entirely from that generally adopted in the preparation of aerated waters, in which the gas and water are brought intimately together in a carbonator and then [illegible] ne method [illegible] physical [illegible] sterilisa [illegible]

THE REJECTION OF A FELLOW PRACTITIONER'S OPINION

To the Editors of THE LANCET.

SIRS,—My attention has been dr[illegible] above heading. In justice to myself [illegible] ment that I admitted declining to foll[illegible] as to treatment The facts, as I stat[illegible] The woman developed unfavourable [illegible] H W Joyce was [illegible] that the case wa[illegible]

[illegible] Hospital, who, after her return to town early next morning, had the case under her personal supervision until the removal of the patient to the infirmary [illegible]

I am, Sirs, yours faithfully,

CATHERINE CHISHOLM, B.A., M.B., Ch.B. Vict

Albert Bridge road, Battersea, Feb 20th, 1905

*** We have had an interview with Miss Chisholm and as a consequence are happy to publish her letter. The coroner's jury could not have understood the circumstances and Miss Chisholm's attitude has been misinterpreted She did not notify the case as one of [illegible] medical profession and it is particularly hard upon her to receive a public rebuke for self sufficiency on the threshold of her career.—ED L.

THE ADMINISTRATION OF ANÆSTHETICS BY DENTISTS.

WE have received a letter asking us if a registered dentist not necessarily holding any save a dental qualification can legally administer anæsthetics. As far as legality goes in the strict sense of the word anyone can administer anæsthetics so long as his purpose is not [illegible] be given by properly qualified medical practitioners. The registered dentist as such is not in a position to conduct the administration of anæsthetics. We all know that nothing is easier than to produce anæsthesia upon a healthy subject in favourable circumstances but nowadays at least we all recognise that the procedure may be a most difficult and dangerous one, one which should not be undertaken by any save a fully qualified medical man who has experience.

AN EXTRAORDINARY PROPORTION OF FEMALE BIRTHS

To the Editors of THE LANCET.

SIRS,—Of 55 births recorded during last year in Carson City, Nevada, only one was a male The causes underlying the differences in sex (if, in fact, there are any causes other than chance) are not only matters of great interest but of importance as well. Carson City, where this extraordinary proportion of female births occurred, has in its population a much greater proportion of males than almost any other city in the States, it being a western mining town. Can it be that this is an effort of nature to correct the ratio? If so, has this circumstance been observed elsewhere? I am, Sirs, yours faithfully,

Albany, N Y, Feb 9th, 1905 BARRINGTON KING.

EMPIRE LINEN MESH FABRIC.

THIS fabric, formerly known as Kneipp linen mesh, has been improved with respect to its value as a material suitable for underwear In future, we are informed that the York street Flax Spinning Company, Limited, of Belfast, which has a London agency at 2, Milk street, E C, intends to call the material Empire linen mesh. *We have already pointed out the advantages of this interesting* material The Empire linen mesh is a knitted elastic fabric which, while keeping the body warm and comfortable, freely allows of the escape of perspired products To the individual who has been accustomed to wear wool next to the skin the material at first feels relatively cool but after a time this feeling disappears and a woollen material if subsequently worn feels somewhat heavy and oppressive by contrast. The fabric is exceedingly cleanly in use and a proof of its ventilating property is afforded in the fact that unlike woollen garments it is not stained or destroyed by the perspiration at the armpits

FLANNELETTE

To the Editors of THE LANCET.

SIRS,—With respect to Mr S Bradbury's interesting letter I may [illegible] be bought retail [illegible] a yard. I do not [illegible] xcessive, but this [illegible] r varieties than this firm stocks are sold, but if so, where? If flannelette can be satisfactorily and permanently rendered fireproof at the cost of 1*d* a yard let the State buy up and abolish the patent rights and then forbid the sale of the inflammable form I am, Sirs, yours faithfully,

Feb. 17th, 1905 A SURGEON

THE R E D BROTHERHOOD

TH[illegible] ls, sends us a [illegible] if ever a title [illegible] matter of fact, the sanguinary confraternity have only entered into a league to prevent boys under 16 years of age from smoking. Believing that it is unwise and wrong to let small boys make rash promises not to smoke until they are 21, the founder of the society has fixed the age at 16 years In his letter he rightly says "Boys do not want sermons, nor do they need to have harrowing pictures of their internal economy shown to them We [illegible] matter when they see [illegible] book issued by the soci[illegible] make prigs of the boys but to form a good healthy opinion among the boys themselves" These two quotations clearly indicate the lines upon which the Rev B S Low is working and we wish him every success in his undertaking The evils of smoking have been so exaggerated that anti tobacco pronouncements have lost much of their force, their inaccuracy being so obvious. But no boy needs the influences of tobacco and all boys are better without the acquisition of a habit that if indulged in excessively may be very mischievous The title of the brotherhood is explained by the following motto [illegible]

THE KING AND THE DEVONSHIRE HOSPITAL.

IT will be remembered that a few months ago His Majesty the King visited the Devonshire Hospital, Buxton, and promised to give that [illegible] trusted [illegible] ad the [illegible] ts it is [illegible] in our [illegible] al with [illegible] h sli fe [illegible] under the portion of the table upon which the patient lies The top of the table, the head rest, and the foot rests can be set to any angle by pressing a lever which in the case of the two latter portions actuates a locking bolt. The top of the table is fixed by a rachet and pawl. The table itself has four legs, two of which are provided with wheels about four inches in diameter, while the other two are plain and can be adjusted in height by a kind of levelling screw. When standing on the two plain feet and the two wheeled ones the table is practically immoveable, but when it is desired to move it the two plain feet can be lifted off the floor and a single leg provided with a wheel brought into action. The table then standing on three legs can be easily moved. Altogether it is a well-devised piece of apparatus.

AN IMPROVED HAMMOCK FOR INVALID RAILWAY TRAVELLERS.

THE means at present adopted by railway companies for the conveyance of their invalid passengers are greatly in need of improvement and we welcome any attempt which has for its object the comfort and convenience of the sick or infirm traveller. On Feb. 17th Miss M. C. Horne exhibited at the terminus of the Great Central Railway an improved form of hammock which, so far as a stationary carriage allowed it to be tested, would seem to possess certain advantages. The improvements in the hammock, which otherwise differs but little from the ordinary canvas form, consist chiefly in (1) a bolster affixed transversely midway between the head and the foot of the hammock; and in (2) flaps running along either side of the hammock for the purpose o more conveniently covering the occupant and as a means of holding hot-water bottles. In use the hammock is first affixed by means of a brass attachment to one side of a carriage between the door and the window, the canvas being allowed to lie along the seat of the carriage. The invalid is then assisted to the hammock, the bolster serving the purpose of a seat and preventing the patient from slipping out of position. The foot of the hammock is then raised and fixed in position at the opposite side of the carriage. Across the under side of the hammock and parallel with the bolster is a strap which is attached to both sides of the carriage, its object being to prevent lateral movement. It is said that beyond a slight rocking movement in the direction of the length of the body but little vibration is felt by the patient, but we cannot speak from personal experience of actual travelling. It has been suggested by one railway company that the cost of the appliance would work out at four third-class fares, plus 2*s.* 6*d.* for the loan of the hammock. This would be a moderate charge and would enable many invalids to take advantage of the railway as a means of transit who cannot do so now on account of prohibitive fares. Should the new hammock prove on more thorough trial to possess the advantages claimed for it, including, of course, cheapness, one obvious use to which it might be put would be to send hospital patients to convalescent homes sooner than it is possible to do now and thus to set free many beds.

PRESCRIBING AT RANDOM.

To the Editors of THE LANCET.

SIRS,—My attention has been called to a paragraph in your valuable paper wherein you comment somewhat adversely upon the action of the Potters' Insurance Co., Limited, who recently issued to all the certifying surgeons a circular letter calling their attention to two samples of mouth wash specially prepared for the use of workers in lead processes. As the original maker of the first of these mouth washes—which I gave the name "Fo-Mo" to—permit me to say that in order to prevent what you designate as "random prescribing" I shall be delighted to send the formula to any member of the profession on receipt of card. I may say that "Fo-Mo" contains none of the ingredients mentioned in your paragraph and that, with the exception of 2 per cent. acid. carbolic., it is *purely vegetable*, as stated on my label. While admitting the capability of a medical man to prescribe suitable mouth washes I would point out the *in*ability for any chemist to make up the prescriptions at the price we sell "Fo-Mo," and as working men are to use it the price must be within their reach. The gentleman who has so strongly recommended it to the notice of his colleagues was fully aware of the constituents of the preparation and I can only marvel at the lack of confidence in his recommend.

I am, Sirs, yours faithfully,
GEO. SWINNERTON, M.P.S.

Stafford street, Longton, Feb. 17th, 1905.

⁂ We may point out to Mr. Swinnerton that we did not mention the names of the washes. We said that according to our analysis the one contained wintergreen, boric acid, and other ingredients. We continued: "In the other carbolic acid appeared to be the chief constituent." "The other" was Fo-Mo.—ED. L.

MALADVERTISEMENT.

WE have received from the Managing Director of the Capsuloid Company, Limited, a protest in respect of a paragraph published on Jan. 21st under this heading. The managing director says that it is quite untrue that his company has made use of our notice of their wares "to publish or at any rate to hint that THE LANCET has recommended capsuloids for falling out and prematurely grey hair." Our opinion to the contrary was founded on the fact that we have received communications at this office asking, in view of the advertisements of the Capsuloid Company, Limited, whether capsuloids are good for baldness. The error into which the public has fallen has been brought about by the wording of the advertisements and this we now learn from the managing director the company "have not the slightest hesitation in changing."

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to acknowledge the receipt of the following additional contributions?—Amount previously acknowledged, £38 15*s.*; Dr. W. M. Harman, £1 1*s.*; and Mr. Edward L. N. Hopkins, 10*s.* 6*d.*

I am, Sirs, yours faithfully,
ALEXR. P. FIDDIAN, Treasurer.

23, The Walk, Cardiff, Feb. 21st, 1905.

◆

T. B.—Our correspondent is strongly advised not to take the course that he proposes. The amount of carelessness displayed must be a matter of question and we have not heard the version of the locum-tenent, but if the principal makes himself the accuser he will run serious risks. Moreover, in our opinion, whatever he may feel it his duty as principal to say to the locum-tenent he is not justified in exciting public prejudice against him.

T. L.—Our correspondent's question is too vague to answer definitely. As a rule in examining for the thermal death-point of microbes the culture of the organism to be tested is examined at temperatures of between 50° and 65° C., the organism being exposed to such temperatures for a period of ten minutes. Spores, of course, are more resistant than is the organism itself.

Tic.—It seems to us that the matter is one for mutual arrangement. No agreement between principal and assistant would be likely to take such a contingency into consideration so that no definite rule exists on the matter. Our feeling is in favour of the principal receiving the money and defraying the assistant's expenses.

M.R.C.S., L.R.C.P.—1. Our correspondent would not be justified in allowing a layman to treat patients by means unknown to himself; if the means are unknown there can obviously be no medical supervision. 2. Certain details of medical treatment can be, and often are, carried out by laymen under medical supervision.

Poupart.—We agree with our correspondent's views, but it would be a mistake not to recognise the arguments in favour of having the post-mortem examinations occasionally performed by an outsider. We have already noticed the situation.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "To THE EDITORS" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol II of 1904, which was completed with the issue of Dec 31st, and the Title page to the Volume, were given in THE LANCET of Jan 7th

VOLUMES AND CASES

VOLUMES for the second half of the year 1904 are now ready Bound in cloth, gilt lettered, price 18*s*, carriage extra

ear s numbers are also ready.

Cl y post 2*s* 3*d*

to the Manager, accompanied

by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch *of their Journals* and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received —*Guernsey Advertiser and Weekly Chronicle, Westminster Gazette, Engineer, Welsh Coast Pioneer, Richmond Herald, Glasgow Herald Freeman's Journal The Scotsman, Highland News Evening News, Morning Leader Manchester Courier, Sussex Daily News, Dublin Times, Birmingham Post Notts Guardian, Dublin Express, Bradford Observer, Hereford Mercury, Sanitary Record, Local Government Chronicle Mining Journal Bath Weekly Argus, Glasgow Evening Times, Surrey Advertiser, &c*

not occur till after birth and is therefore easily studied, the epithelium lining their conjunctival sac remaining as a single layer until after separation has taken place.

THE MANNER AND DATE OF SEPARATION OF THE EYELIDS IN THE HUMAN FŒTUS.

In looking up the literature of this subject I was at once struck by the number of different dates given by various authors for the separation of the lids, varying from the seventh month till shortly before birth. When we remember that a certain number of living children are born at the seventh month and reflect that these children are not born with closed eyelids like the cat or dog we realise that there must be a fallacy somewhere. The age and length of the fœtuses examined were as follows:—

Length.	Approximate age.	Condition of lids.
24 c.m.	Fifth month.	Lids separated.
21½ c.m.	" "	" "
20 c.m.	" "	" "
11 c.m.	Fourth month.	Lids joined, separation commencing anteriorly, growing-out of eyelashes.
9 c.m.	" "	" "
7 c.m.	Third month.	Firmly united.
4½ c.m.	Tenth week.	Primary union just taking place.

The above fœtuses were examined both macro- and microscopically. The description of the condition of the lids and conjunctiva in the ten weeks' fœtus (four and a half centimetres) I have already given. A fœtus of the third month (seven centimetres) showed the eyelids firmly united together by epithelium, with downgrowth of the epithelium from the junction of the lids commencing to form the Meibomian glands and hair follicles, the former appearing rather before the latter. During the early part of the fourth month (fœtus nine and 11 centimetres) the eyelashes grow out from between the closed lids and materially assist in the separation of the anterior portion of the union, which is the first to yield, the uniformity of the curve of the lashes being produced by the impinging of the growing lash on the opposing eyelid.

I think that cases of congenital trichiasis[3] may be accounted for by irregularity or mal-union of the lids, allowing the lashes to grow out straight without impinging on the opposite eyelid and so altering the direction of the follicle as to produce non-uniformity of the curve. After separation of the anterior part of the junction of the lids there is a degeneration of the epithelial cells of the posterior parts of the union, better seen in the cat about the third day after birth than in the human embryo. Final separation takes place by degeneration of the epithelium in the mesial portion of the junction, which is therefore the last to yield.

It has already been seen in the snake that the portion of the conjunctival sac which is permanently closed is lined by a single layer of epithelium of embryonic character. In the cat (third day after birth) the epithelium over the surface of the bulbar conjunctiva remains as a single layer until separation of the lids has taken place (ninth day), so I think it may be taken that thickening of the bulbar conjunctiva is positive evidence of separation having taken place. This thickening of the conjunctival epithelium I found took place in fœtuses over 20 centimetres in length—viz., at the beginning of the fifth month, the thickening taking place first, and spreading from the epithelial bond of union between the eyelids. Another argument in favour of the thickening of the epithelium being due to the separation of the lids is the fact that when the lids have failed to unite, as occurs in cases of clefts of the lids or in cases where the lids are completely absent (cryptophthalmos), the epithelium is very much thickened, so much so that it resembles skin. Thus I think the comparative frequency of the so-called dermoid patches of the conjunctiva so often associated with deformity of the eyelids is explained. Further evidence that the lids have separated at the fifth month is found in the fact that the Meibomian glands are actively secreting at that date and it is possible to squeeze secretion from them; microscopically this secretion is made up of fatty material with a quantity of epithelial cells.

DESCRIPTION OF THE CONJUNCTIVA AT BIRTH.

The following observations were based on the examination of three healthy fœtuses at full term in a good state of preservation. When the child is born the eyelids are tightly closed, the skin being thrown into numerous wrinkles and covered with a fatty material. The margins of the lids are usually in contact with each other, but occasionally the upper lid is found overlapping the lower.

The epithelium.—Over the lower part of the tarsus this is much thicker than it is in the adult conjunctiva, owing, no doubt, to its close proximity to the margins of the lids, in which thickening first begins. It is here some five cells in thickness and is the only situation in which it is thicker than in the adult, and, like the rest of the epithelium of the conjunctiva, there is an absence of any flattened epithelial cells on the surface, the cells being cuboidal in shape. On the anterior part of the retro-tarsal fold the epithelium is only from two to three cells in thickness, being much thinner than the adult epithelium in that region. That of the bulbar conjunctiva is again not so thick as that of the adult, but next to the epithelium covering the tarsus it is the thickest part of the epithelium of the conjunctiva at birth. In the fornices at the bottom of the folds the cells show signs of mucoid change to such an extent that in the three cases examined the basement membrane was completely bare in places and would have allowed a ready entrance of organisms to the subconjunctival tissues. The corneal epithelium is about three cells in thickness, but to compensate for this there is a great thickening of the substantia propria, both in comparison to the thickness of the sclera and to that of the adult cornea. The subconjunctival tissue in the region of the bulb contains a quantity of elastic fibres which are finer than those in the adult conjunctiva. There does not seem to be any elastic tissue in the sub-epithelial conjunctival tissue covering the tarsus.

In the fornices the subconjunctival tissue is very loose and rich in blood-vessels and lymphatic spaces but there is a complete absence of leucocytes which do not appear until after birth when the fornices become filled with mononuclear leucocytes and a few plasma cells which spread later to the subconjunctival tissue covering the tarsus. In other lymphoid tissue, such as the tonsil, mononuclear leucocytes are present for several weeks before birth and are evidently produced from the cells of those structures. In the conjunctiva, therefore, the lymphoid tissue is probably the result of irritation and is of new formation. This will be discussed in more detail when dealing with the histological changes in inflammatory affections of the subconjunctival tissue.

There is a small point in the anatomy of the fornix to which I wish to draw attention. At the extreme inner end of the upper fornix the loose lymphoid tissue ends in a triangular fold which can only be demonstrated by dividing the eyelids and turning them back; it is seen to be connected with the main fornix by a very narrow band. This is not an uncommon situation for polypoid tumour, which in the case I have examined consisted of lymphoid tissue covered by epithelium. Several of these tumours have been described under different nomenclature, such as supernumerary caruncle. They arise from this triangular piece of lymphoid tissue becoming œdematous and then being nipped between the globe and the eyelid. That this was the case was shown to me in the following way. In examining a number of stillborn children I found one in which during a difficult labour hæmorrhage had taken place into this small mass of loose tissue, with the formation of a red polypoid mass which protruded from between the eyelids; on section it simply consisted of a mass of blood-clot covered by epithelium.

The glands opening on to the surface of the conjunctiva, with the exception of the mucous glands, seem to be inactive. The secretion of tears from the lacrymal gland does not take place until some time after birth. There are no glands of Henle present at the time of birth, these being formed subsequently as the result of irritation.

THE HISTOLOGICAL CHANGES IN THE CONJUNCTIVA AS THE RESULT OF INFLAMMATION.

The epithelium.—The changes in the epithelium depend on whether it is kept moist by the lacrymal secretion or whether it is allowed to become dry. If moist the cells proliferate and undergo greatly increased mucoid changes, being cast off in large numbers in the discharge. The exudation into the subconjunctival tissue causes the surface epithelium to be thrown into folds between papillary formations so that two epithelial surfaces lie in contact with each other, and it is the cells of these surfaces which show the most extensive mucoid change, commencing at the bottom of the folds, causing some irregularity of the basement membrane and giving the appearance of new gland formation. The glands of Henle are of this type, the regularity of their formation along the upper margin of the tarsus being due to this being the situation in which the fixed palpebral conjunctiva joins the loose conjunctiva of the fornix, where folding is more liable to take place; a large gland of this type is often seen at the inner end of the tarsus (E. T. Collins).[4]

---

[3] Stephenson: Transactions of the Ophthalmological Society, vol. xiv.

Although this is perhaps the most common way in which the so-called new glands of the conjunctiva are formed there may be observed near the junction of the moist and dry epithelium a somewhat different modification, which occurs in conditions due to exposure and to chronic inflammation, such as ectropion, secondary xerosis, and papillomata of the conjunctiva which have been exposed in the palpebral fissure. As the result of this exposure the epithelium becomes thickened and dips down into the subepithelial tissue in the form of papillæ. Mucoid degeneration of the epithelial cells in the centre of these papillæ takes place with the formation of a flask-shaped mucous gland.

The openings of these new mucous glands are often occluded by epithelial débris, with the result that the lower end becomes distended and forms a cyst. These cysts on the palpebral conjunctiva are extremely common and one conjunctiva may contain many thousands of them. They are lined by more or less flattened epithelium three or four cells deep and contain epithelial débris which is sometimes calcified; on the bulbar conjunctiva they are comparatively rare but when they occur they are usually single and appear as transparent cysts containing clear fluid; they are lined by epithelium having many tuft-like processes, the cells of which are undergoing mucoid change and supply the fluid for the interior of the cyst.

If the epithelium be dry, as in cases of ectropion, the cells proliferating still remain attached to the underlying epithelium and undergo a process of keratinisation with the formation of keratin, keratohyalin, and prickle cells. The basement membrane becomes irregular and processes of epithelium dip down into the subconjunctival tissue, forming papillæ. In fact, the epithelium of the conjunctiva which is exposed resembles very closely in structure the true skin, with the exception of the absence of glands, hair follicles, &c.

Of great interest is the fact that when again moistened, as after an ectropion operation, the epithelium goes back to resemble macroscopically its former state, probably in consequence of softening of the superficial layers, with subsequent mucoid change in the deeper layers. From this it seems that the presence of lacrymal fluid is necessary to the formation of mucin by the epithelial cells. As the condition [illegible] this drying of the epithelium it [illegible]

[illegible] —Xerosis is usually described as divided into epithelial or primary xerosis and essential shrinking of the conjunctiva or secondary xerosis. Pathologically the changes in the epithelium may be looked on as identical, except that those in the essential shrinking form are much more marked and are characterised by the formation of papillæ. Both conditions are due to drying of the epithelium owing to the absence of lacrymal secretion. In epithelial xerosis the lacrymal secretion is deficient owing to general malnutrition, whilst in the essential shrinking form the deficiency is due to chronic inflammation of the subconjunctival tissue, which contracts around the orifices of the lacrymal ducts, or possibly in some cases to primary degeneration of the gland. As a result of the deficiency of lacrymal secretion the epithelial cells seem unable to form mucin, as in ectropion; this fact and the changes resulting from it will be shown in greater detail immediately while describing the two forms of xerosis.

The primary form of epithelial xerosis.—In a paper read before the Ophthalmological Society[5] last year I gave a detailed account of six cases of this disease which I had had the opportunity of examining both clinicallly and histologically. The chief conclusions arrived at were:—1. That the minute bubbles seen on the surface of the plaques were due to the beaten-up Meibomian secretion. 2. That the xerosis bacillus was simply a saprophyte growing in the Meibomian secretion similar to the smegma bacillus growing in the preputial secretion and was not found in the tissue of the conjunctiva. 3. That the change in the epithelium was one of keratinisation, prickle cells, keratohyalin granules, and keratin being found in it. 4. That as a result of keratinisation and absence of mucoid change in the cell the surface tension of the conjunctiva was raised and therefore [illegible] not moisten the surface but [illegible] secretion containing the so- [illegible] e.

[illegible] *or essential shrinking of the conjunctiva.*—It is extremely doubtful if this trouble ever occurs as a primary disease but is always secondary to some form of chronic inflammation which at the time that the disease appears may not be active—as, for instance, in the case of pemphigus when quiescent.[6] Besides pemphigus it follows trachoma, lupus, burns, and cicatrices of the conjunctiva—in fact, any disease leading to drying of the conjunctiva, either by direct invasion of the lacrymal gland or by blocking of its ducts from cicatricial contraction. The change in the epithelium is similar to that previously described in epithelial xerosis but, in addition, papillæ of epithelium are formed by the downward growth of the epithelium into the underlying tissue. A case of this kind has been recorded by E. Treacher Collins,[7] which showed papillæ similar to those formed after the exposure of the epithelium in ectropion. In a case of lupus associated with essential shrinking I found similar changes in the epithelium.

The condition of the underlying subconjunctival tissue depends on the cause of the disease. In trachoma the trachomatous follicle may be present. In lupus typical giant-celled systems with epithelioid cells, &c., are found; in pemphigus, fibrous tissue. The plaques seem especially to pick out the more scarred portions of the conjunctiva. In three cases following on trachoma which I have had the opportunity of examining the changes in the epithelium were exactly similar to those described under epithelial xerosis with the exception that the basement membrane in one case was extremely thick, the keratinised layer being also very thick. Adherent to the surface was a definite membrane formed of Meibomian secretion and epithelial débris. In one case the whole lower palpebral conjunctiva was covered with this membrane which was very adherent and when scraped off re-formed in a few days. To this class I believe belong some of the cases classed as membranous conjunctivitis with persistent membranes.[8]

Before passing to the description of the diseases of the subconjunctival tissue it is necessary to describe in more detail the character of the cells found in the subepithelial layer of the normal conjunctiva.

Description of the cells forming the subepithelial layer.—These consist of three varieties: (1) those of hæmic origin; (2) those derived from the connective tissue; and (3) those of uncertain origin.

CELLS OF HÆMIC ORIGIN.

[The staining reaction and character of the polynuclear leucocytes (neutrophiles) were then described.]

Spider cells.—Spider cells are cells of curious branching shapes which are in reality polynuclear leucocytes fixed in the process of amœboid movement. That this is their origin seems evident because: (1) they are found principally at the edges of sections where immediate fixation of the tissue would result when placed in the fixing agent; (2) when examined carefully their elongated nucleus can be made out; (3) they are found principally in sections of acute inflammatory processes where polynuclear cells are seen; (4) if the tissue is not fixed rapidly these cells are not seen to nearly the same extent; and (5) they are found especially in the denser tissue where they cannot assume their rounded shape.

[The character and origin of the poly-eosinophile and basophile were then discussed.]

Connective tissue cells.—Connective tissue cells in the conjunctiva are of two types: those of the (*a*) *deeper layer*, which are elongated and of a wavy outline and arranged parallel to the surface. With Pappenheim's method the nucleus stains pale blue, with the nucleolus staining bright red. The cytoplasmic tails also stain pale red. In this layer of the normal conjunctiva there are, comparatively speaking, no other cells but these, except perhaps an occasional plasma cell or leucocyte. (*b*) In the *superficial layer* the cells become of a much larger type and stain more darkly. Their shape is oval and the protoplasm is better marked. The nucleus and protoplasm stain blue, with a bright red nucleolus. They have often no tails or only very small ones.

[7] Transactions of the Ophthalmological Society, vol. x., 1890, p. 62.

[8] S. Morton and E. T. Collins: Transactions of the Ophthalmological Society.

The endothelial and perithelial cells of the blood-vessels are flattened in the capillaries of the superficial layers of the connective tissue in the normal conjunctiva. They stain dark green, like some of the connective tissue cells, with red nuclei. Directly any proliferation takes place they become larger and more rounded in shape, either bulging into the lumen of the blood-vessel or protruding externally. Their cytoplasm takes up the pyronine of the Pappenheim stain much more readily. They migrate into the surrounding tissue undergoing mitosis and when in that stage are indistinguishable from a plasma cell from which I believe this cell is derived. Against this it must be remembered, as has been pointed out by Whitfield, that there is no distinctive stain for plasma cells and that any young cell takes on a basic staining reaction and that therefore the recognition of a plasma cell also depends on the characteristic appearance of its nucleus which is destroyed by the mitosis taking place. But this point, I think, shows the possibility of the formation of a plasma cell from the endothelium or perithelium of vessels. These round, darkly staining, migrating endothelial cells seem to be identical with the cells called clasmatocyte by Ranvier and Marchand, which name therefore I shall adopt in speaking of them. The endothelial cells are also strongly phagocytic and often contain cell inclusions.

Cells of doubtful origin.—*Lymphocytes* are divided into large and small, the large cell being the smaller cell in a more highly developed state. Their nucleus stains dark blue with Pappenheim's method whilst the cytoplasm stains pale red. They are formed in the follicles of the lymphatic glands, probably from their endothelial lining, and from there are carried in small numbers into the blood stream, but, unlike the polynuclear leucocytes, they are not increased in the blood in inflammatory conditions (absence of chemiotaxis), although enormous numbers are found at the site of inflammation, so that they must be produced locally by rapid division of the few cells brought by the blood stream as is held by some observers or else from the endothelium of the part which, I think, is most probable.

The relation of the large mononuclear leucocyte to the lymphocyte is at present doubtful. But since they are found together in all situations in which they occur and the staining reaction of their cytoplasm being the same, although the nucleus is of a slightly different shape, I think that they probably belong to the same generic type. The large mononuclear leucocyte is very difficult to recognise in tissue, it being confused, on the one hand, with the clasmatocyte and, on the other, with the large lymphocyte. Even in smear preparations of the fluid taken from serous cavities it is often difficult to distinguish between the wandering endothelial cells and the mononuclear leucocyte, although this difficulty is not admitted by some of the authorities. It is therefore obvious that its recognition in the tissue is so much the more difficult. It is admitted by all pathologists that the lymphocytes and the large mononuclear cells are intimately related to the plasma cell and are always found together, although one may be in excess.

Plasma cells.—Of all the cells found in the body perhaps none has given rise to so much discussion with regard to its origin as the plasma cell. Unna, who brought this cell into so much prominence, holds that it is derived from the connective tissue. Other observers say that it is derived directly or indirectly from the lymphocytes. Although the plasma cell has perhaps been given undue prominence it is without doubt one of the most important cells in conjunctival inflammation. It is found normally in small numbers in the conjunctiva beneath the epithelium, and its numbers are greatly increased in all inflammatory affections, especially of the more chronic type, such as trachoma. Its situation when present in large numbers is chiefly around the vessels and hence its position in the superficial layers of the subepithelial tissue. It seems to be slightly amœboid but not nearly to the same extent as the polynuclear leucocytes. When stained by Pappenheim's method the cytoplasm stains a uniform dark red without granules, whilst the nucleus stains dark blue and is very granular, containing a nucleolus which stains red. There are always to be found cells which pass in staining reaction into the lymphocytes, on the one hand, to which they are very closely allied, and into the endothelial or perithelial cells on the other.

In addition to the above cells which are found in normal conjunctivæ there are two types of cells which are formed only in inflammatory conditions.

Epithelioid cells.—These cells are found in trachoma, tubercle, leprosy, syphilis, &c., and are arranged around the foci of the disease. Outside them there is always a layer of mononuclear leucocytes from which they are most probably derived by the action of the toxins on the mononuclear leucocytes. In structure they are intermediate between the wandering endothelial cells (clasmatocytes) and the large lymphocytes.

Giant cells.—Giant cells in the conjunctiva are of two types: 1. The chorioplaques, which are derived from the plasma cells, most probably by incomplete division of the cytoplasm. These cells are found in all inflammatory conditions of the conjunctiva. 2. Giant cells proper. The giant cells proper are always more or less rounded in the conjunctiva, owing to the laxity of the tissue and are derived from the endothelial cells by division of the nuclei, with imperfect division of the protoplasm. These cells are probably due to the action of the toxins producing cell monstrosities. They occur frequently in all chronic inflammatory conditions of the conjunctiva around foreign bodies, &c., the conjunctiva having a great proclivity to form this cell. Like the endothelial cells they are also phagocytic. These two types of giant cells stand in the same relation to one another as the endothelial and plasma cells from which they are derived.

The Erasmus Wilson Lectures

ON

PERITONITIS, A BACTERIOLOGICAL STUDY.

Delivered before the Royal College of Surgeons of England on Feb. 20th, 22nd, and 24th, 1905,

By LEONARD S. DUDGEON, M.R.C.P. Lond., M.R.C.S. Eng.,

SUPERINTENDENT OF THE CLINICAL LABORATORY AND DEMONSTRATOR OF CLINICAL PATHOLOGY AT ST. THOMAS'S HOSPITAL; GILLSON SCHOLAR IN PATHOLOGY OF THE SOCIETY OF APOTHECARIES; ERASMUS WILSON LECTURER, ROYAL COLLEGE OF SURGEONS OF ENGLAND;

AND

PERCY W. G. SARGENT, M.A., M.B., B.C. Cantab., F.R.C.S. Eng.,

RESIDENT ASSISTANT SURGEON AT ST. THOMAS'S HOSPITAL; ERASMUS WILSON LECTURER, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

LECTURE II.[1]

Delivered on Feb. 22nd.

The Bacteriology of Appendicitis.

Mr. President and Gentlemen,—This subject has been investigated by numerous observers but the most important communications are those by Tavel and Lanz in 1893 and 1904. The valuable contribution to the bacteriology of this subject which they made in 1893 has formed the basis upon which most of the work of the present day rests. It is most unfortunate, however, that so much time has been given to the bacteriology of appendix abscesses as it was hardly probable that the actual cause of appendicitis would be found by examining the contents of an offensive abscess cavity. There is no doubt that the chief interest in this subject centres around the *colon bacillus*. At one time it was thought that this was the most important organism in the etiology of peritonitis, whether due to appendicitis or otherwise. Other observers adopted an entirely different view—namely, that the colon bacillus is an organism which is very easy to cultivate and grows very rapidly and, therefore, the more delicate but more virulent organisms are never isolated. This idea has become widely popular and is the view which is generally accepted at the present day. *In 1898 Veillon and Zuber announced* that they had sufficient evidence to show that certain [illegible] most important part in the [illegible] Tavel and Lanz in their [illegible] give support to the views of Veillon and Zuber. Hewetson published a preliminary paper on the bacteriology of peritonitis and failed to find any evidence to show that anaerobic organisms were of any importance in appendicitis. It has already been stated that many people hold that the colon bacillus outgrows the more delicate micro-organisms which are most concerned in the bacteriology of appendicitis. It is the streptococcus pyogenes, the pu[illegible] which are supposed [illegible] cillus coli.

---

[1] Lecture I. was published in The Lancet of Feb. 25th, 1905, p. 473.

The r[illegible] to appendicitis.—Those who have devoted time to the study of this subject must have met with cases which were due to this coccus but no one has been able to do more than suggest that the streptococcus pyogenes is a common organism in this disease. It is true that some of the older writers considered that almost every case of peritonitis was due to the streptococcus pyogenes but a complete bacteriological investigation was seldom made and it is extremely doubtful if there was sufficient evidence to support this idea. It is impossible to be certain of the nature of some of the micro-organisms which have been described in cases of appendicitis as "streptococci," because this does not by any means imply that the organism in question was the streptococcus pyogenes. In all our cases we have made every effort to prove the nature of the organism which we were investigating. Cover-slip preparations and aerobic and anaerobic cultures of the peritoneal exudate were made in the large proportion of cases. In every instance in which we found chains of cocci in film preparations of the pus or peritoneal fluid we also grew the organism on artificial media. It can therefore be said that if there was no evidence of the *streptococcus pyogenes by any of the* methods which we employed it was extremely unlikely that the organism was present.

E. M. Corner appears to be of the same opinion as Harvey Cushing, and many others, who hold that the streptococcus is usually lost in artificial cultures because, he says, "although that (streptococcus) is one of the most widely distributed of organisms it is very easily killed and lost in mixed cultures and may literally vanish before a member of the colon group." It is hardly probable, however, that we should have failed to find a streptococcus in either the film preparations of the pus or in the various cultures employed in each case. Experience does not teach us that the streptococcus pyogenes dies out or cannot be isolated in the presence of the colon bacillus. It is true that in some cases of appendix abscess cocci have been present in cover-slip preparations of the pus, when the organisms have not been cultivated. We do not attach any importance to this fact as the pus in these abscesses may contain numerous micro-organisms which are never cultivated, in fact, the pus in these abscesses sometimes appears to contain enormous numbers of micro-organisms of every shape and size, because we are *merely examining the contents of the intestine.* If, however, diffuse peritonitis supervenes on a case of appendix abscess there is never any difficulty in isolating the micro-organisms which are in the peritoneal cavity, provided, of course, that the bowel contents are not free in the general cavity. If this occurs we have an exactly similar condition to which we have already referred. There is not a single instance among our cases in which the streptococcus pyogenes was obtained from the peritoneal cavity in acute diffuse non-perforative peritonitis due to appendicitis. If the streptococcus pyogenes is the important organism in appendicitis which Cushing, Corner, and others would have us believe, then we ought to have found it in some of the instances of this variety of peritonitis, which we have not been able to do. Here is the direct proof which has long been wanted and it shows that the streptococcus pyogenes is seldom present in the peritoneal exudate in appendicitis. In conclusion, we would like to point out still further that in those cases of peritonitis in which the streptococcus pyogenes is found in the peritoneal cavity the prognosis is practically hopeless. If this organism were, therefore, frequently present in the peritoneal exudate in appendicitis the mortality would be very much higher than it is at present.

The pneumococcus.—Barbacci, Kregius, and others have stated that they considered that the pneumococcus was an important organism in the bacteriology of perityphlitis, while J. H. Bryant has offered the suggestion that the pneumococcus might possibly be found to be a very important organism in this disease, if only a more careful search were made. J. Eyre has found the pneumococcus quite recently in the interior of the appendix from a case of acute appendicitis. Veillon and Zuber and others have obtained *a pure culture of the pneumococcus from* the peritoneal exudate in cases of appendicitis. In one of our instances of appendix abscess we isolated the pneumococcus with the colon bacillus. This is the only case in which we cultivated the pneumococcus either from the pus in the appendix abscess or in the peritoneal exudate in peritonitis associated with appendicitis. There is little doubt that if the pneumococcus was the important organism in appendicitis which it has incorrectly been assumed to be we should have obtained pure cultures of the organism from the peritoneal exudate in some of our cases quite apart from the presence of the coccus in a localised abscess. The usual tendency of the pneumococcus is to produce diffuse peritonitis without any of the changes which are met with in perforative peritonitis. In the case of appendicitis described by Veillon and Zuber there was a large quantity of greenish-white, thick, non-offensive pus present in the peritoneal cavity. We have not seen a single example of appendicitis of this nature.

The pathogenic staphylococci.—Tavel and Lanz were the first to demonstrate clearly that the pathogenic cocci might be the cause of "perityphlitis." It is, however, to Corner that the credit is due of first pointing out their great importance in this disease. In appendicitis, he says, "it seems not improbable that the origin of the acute cases of appendicitis lies with the septic organisms, which injure the tissues and so give the colon bacilli their opportunities." We read throughout the literature of appendicitis and also of peritonitis from other causes the expression "staphylococci" used in the very *widest sense.* It should *not* be necessary to have to mention that it is impossible to obtain any information from such a statement as "staphylococci were present." If all staphylococci were of the same pathogenicity perhaps such a loose terminology might be of little moment, but this is not so. The pathogenic properties of the staphylococcus pyogenes aureus are infinitely greater than those of any of the other staphylococci and even the white staphylococci show all grades of pathogenic virulence. It is unnecessary to produce any further proof to show how incorrect it is to describe various micro-organisms in this manner.

We quite agree with Corner that the "staphylococci" play the most important part in the bacteriology of appendicitis. It has already been shown that the white staphylococci are the most important organisms in many other varieties of peritonitis and we have evidence to show that the same is true of appendicitis. The staphylococcus pyogenes aureus appears to be an organism of much virulence in peritonitis and is thus in direct contrast to the white staphylococcus. There is, however, a still further point to remember, that all cultures of the staphylococcus *pyogenes aureus* do not react in the same manner, as some are very much more virulent than others. It will also be found that a typical culture of the staphylococcus pyogenes aureus may lose all its chromogenic properties when it is subcultured for the first time and Dr. W. Dowson has observed the opposite effect. We have found that the chromogenic properties of this organism and the degree of pathogenicity increase in about the same ratio. There is one fact which appears to be quite certain, that there are many intermediate varieties of staphylococci between the white and the golden coccus.

The results of our experiments with the various white staphylococci obtained from the peritoneal exudate in all cases of peritonitis have been described elsewhere. Although various strains of this coccus were injected into the peritoneal cavity of numerous guinea-pigs we failed to produce suppurative peritonitis in a single instance, and this is exactly what is found to occur in the human peritoneum. It is for this reason that if the white staphylococcus has been isolated from the peritoneal exudate in peritonitis it has usually been considered to be due to "contamination," or that the coccus at least has had an epithelial origin and has had nothing whatever to do with the bacteriology of peritonitis. We, however, have good reason to believe that this view is incorrect. We have found the white staphylococcus in almost every variety of peritonitis; it is by far the most common organism met with in the peritoneal exudate at a distance from the site of origin of the acute lesion and is frequently found in the peritoneal cavity in "the interval cases" of appendicitis. The important bearing which it is found to have on the prognosis of a case of peritonitis, when present in the peritoneal exudate alone or some time previously to the arrival of the colon bacillus, cannot be over-estimated. It does not appear to have any influence in the prognosis of those cases which are due to the streptococcus pyogenes or bacillus pyocyaneus.

We have obtained exactly similar results experimentally. If we injected the white staphylococcus into the peritoneal cavity of a guinea-pig together with the colon bacillus the coccus was found to have effect in preserving the life of the animal in only a few instances. If, however, we injected the coccus into the peritoneum some 20 hours previously to the colon bacillus most striking results were obtained. The guinea-pig which had been inoculated in this way either recovered or lived for several days, finally dying from some cause outside the peritoneal cavity, while control animals inoculated with the same strain of the colon bacillus, the same dose, and in the same manner, died within 24 hours. It is impossible to lay too much stress on these important observations which not only show that this coccus is of the utmost significance in peritonitis but that it has an entirely opposite effect to that which was expected, in fact, we have another illustration of the great service which micro-organisms may render to man and to animals.

We next proceeded to ascertain the action of this white coccus in cases of peritonitis. We used the guinea-pig for this purpose, as we had used it for all our other experiments. We injected definite quantities of a culture of the staphylococcus albus obtained from the peritoneal exudate in a case of appendicitis into the peritoneal cavity of guinea-pigs and examined the exudate at regular intervals. This fluid from the guinea-pigs' peritoneum, which had been injected 15 minutes, one hour, two hours, and 24 hours respectively, was carefully examined. These results are fully described hereafter but it is sufficient to state here that this coccus caused a very large number of leucocytes to appear in the peritoneal cavity of these animals, but while the injections of the colon bacillus carried out in an exactly similar manner also produced similar results the phagocytes were degenerated within one hour from the time of inoculation in the latter case but appeared to be perfectly healthy at the end of 24 hours after injecting the white staphylococcus. There was also much more peritoneal exudate after injecting the coccus than the bacillus. From these data it will be seen that the chief results which arise from injecting the white coccus into the peritoneal cavity of animals are the production of an extensive phagocytosis and also, although we made no attempt to prove this, a selective action of the body fluids. If the colon bacillus and the staphylococcus albus are injected into the peritoneal cavity of an animal at one and the same time it is found that the phagocytes are degenerated just as if the bacillus was injected alone.

The staphylococcus albus, when present in the peritoneal cavity in peritonitis, has, therefore, a definite function to perform and is not a "mere skin contamination" as some would have us believe. The fact that a patient's serum has a marked agglutinative action towards this coccus isolated from the peritoneal cavity in some of these cases of appendicitis is still further proof that the white staphylococcus bears an important relation to peritonitis.

Professor Welch delivered an address before the Congress of the American Physicians and Surgeons in 1892, entitled "Conditions underlying the Infection of Wounds." It was at this address that Professor Welch first drew attention to a white staphylococcus—the staphylococcus epidermidis albus. He directed our attention to the work of Bumm, Garré, Waterhouse, and others who have shown that "large numbers of the pyogenic cocci can be injected into human tissues without effect." These observations are of very great importance in the light of recent work. We have shown similar results from our experiments but with some important distinctions. It is true that there was "no effect" to the naked eye unless a very careful examination was made of the tissues of the inoculated animal or human being, but if an examination of the tissues is made we find that a very decided effect has been produced. Professor Welch clearly shows in his lecture that the white staphylococcus plays a very important part in the healing of an aseptic wound, and still further he refers to a case of peritonitis in which this coccus was found to play an important part. In a fatal case of "hystero-myomectomy" a volvulus of the ileum was found at the necropsy. There was a fibrino-purulent peritonitis present corresponding to the peritoneum covering the ileum, and a pure culture of the white coccus was obtained from the inflamed peritoneum. In concluding his excellent paper Professor Welch expressed the opinion that the white staphylococcus which is found so frequently in aseptic wounds, in stitch abscesses, and in the skin is an attenuated variety of the staphylococcus albus. We have already given our opinion as to whether we consider the white coccus which we have found with such regularity in peritonitis is the same organism as the staphylococcus epidermidis albus of Welch. We should mention here, however, that a stitch abscess is very seldom seen in the wards of St. Thomas's Hospital, although the white coccus has been so frequently isolated from the peritoneal cavity in peritonitis.

Anaerobic micro-organisms and their relation to appendicitis.—Veillon and Zuber published a paper in 1898 on the bacteriological findings of 22 cases of appendicitis. They drew attention to the importance of certain anaerobic organisms which they considered to be the most important organisms concerned in the bacteriology of appendicitis. They described altogether six micro-organisms—namely, the bacillus fragilis, bacillus ramosus, bacillus perfringens, bacillus fusiformis, bacillus furcosus, and the staphylococcus parvulus. All these organisms were found to be strict anaerobes, pathogenic to animals, and constantly present in the pus of appendix abscesses and in the general peritoneal cavity in cases of peritonitis. These observers considered that gangrene of the appendix and the offensive odour of the pus in appendix abscesses were due to these organisms and their toxins gave rise to the toxæmia which was the cause of death in appendicitis. This important communication produced a considerable amount of discussion and many considered that much of the previous work on appendicitis was valueless owing to the investigations of Veillon and Zuber. Tavel and Lanz in their latest communication on the bacteriology of appendicitis appear to have come to a somewhat similar conclusion. They place considerable importance on the presence of the bacillus pseudo-tetanus which is the same organism as the bacillus fragilis of Veillon and Zuber and also to a class of anaerobic bacilli which they describe as the bacilli of malignant œdema. We can state at the outset that we entirely disagree with the results of the investigations to which we have just referred. We employed strict anaerobic precautions in a very large percentage of the cases of appendicitis which we have examined and also in other varieties of peritonitis but failed to find these anaerobic organisms except in one instance. This was an example of appendix abscess in which the appendix was found to be gangrenous. The bacillus coli, a streptococcus, and the bacillus aerogenes capsulatus of Welch were present in the abscess. This anaerobic bacillus was obtained in pure culture from the surface of agar plates incubated under strict anaerobic precautions in Bulloch's jar. The bacillus produced extensive bloody emphysematous œdema when inoculated into the subcutaneous tissues of a guinea-pig and the emphysematous œdema spread very rapidly through the entire subcutaneous tissues of the animal and produced death in 24 hours. The organism was present in pure culture in the subcutaneous tissues of the animal. When it was injected into the vein of a rabbit and the animal was killed two minutes later and then placed in the incubator at 22° C. for 24 hours, certain changes were found which are specifically characteristic of this bacillus. The rabbit was found to be about twice the original size, the eyes were protruding from the animal's head, and there were general subcutaneous emphysema, foaming viscera, free gas in the blood, and emboli of bacilli throughout the various internal organs. Professor Welch considers that the organism is capsulated but we have always failed to demonstrate a capsule to the bacilli obtained directly from the tissues. This bacillus is described by Veillon and Zuber as the bacillus perfringens and is classified as one of the bacilli of malignant œdema by Tavel and Lanz. It is most unfortunate that these investigators should have adopted this classification, as Professor Welch has proved beyond question that the important organism in so-called malignant œdema or emphysematous gangrene is the bacillus aerogenes capsulatus, an entirely different bacillus from the bacillus of malignant œdema, which was considered on the continent to be the cause of emphysematous gangrene until Professor Welch published his important communication. We have dealt with this point more fully in a paper recently brought before the Pathological Society of London on Emphysematous Gangrene of the Extremities.

The case from which we isolated Welch's bacillus made an excellent recovery. The weakest point in the paper by Veillon and Zuber, which appears to have escaped attention, is that if an organism such as the bacillus aerogenes capsulatus was frequently present in the peritoneal cavity in cases of appendicitis, *as they have stated, emphysematous gangrene* of the bowel should be a common lesion instead of an interesting curiosity in pathology, the same condition should be found to occur in the abdominal wall, which is not so, and foaming viscera should be frequently seen at the necropsies on cases of appendicitis, instead of which there has only been one instance of this condition in the post-mortem records of St. Thomas's Hospital for 1904. These few points and our own investigations on the bacteriology of appendicitis are sufficient to show that the work of Veillon and Zuber is only of interest owing to the exceptional results which they obtained. Hewetson, in the communication to which we have already referred, has also failed to confirm the work of Veillon and Zuber.

In almost every case of appendicitis large numbers of cocci, bacilli, and spirilla are present in the film preparations of the appendix abscess which are not cultivated; the contents of these abscesses are simply the intestinal flora in a great many instances.

Bacillus pyocyaneus.—It was originally considered by Koch that this bacillus was non-pathogenic. We now know that it may be extremely pathogenic to man and is often one *of the most virulent of all known micro-organisms to the* small laboratory animals. Cultures of this bacillus do, however, vary considerably in their pathogenic properties. The only question which we wish to discuss here is the relation of this organism to peritonitis. It appears to be extremely virulent when present in the human peritoneal cavity. It does not produce the green pus in the peritoneum such as is often seen in a local abscess. In fact, one is led to believe that virulent cultures of the bacillus which kill patients in a few days do not usually produce any chromogenic staining of the pus although the bacillus may produce large quantities of pigment when grown on artificial media. We have never yet seen green pus in the peritoneal cavity of man or animals even after exposure to the air for some minutes. We consider that the bacillus pyocyaneus will in the large majority of cases cause death when present in the peritoneal cavity and is only less virulent than the streptococcus pyogenes in the fact that it takes a little longer to cause death.

The bacillus coli and its relation to the cause of appendicitis.—In every variety of appendicitis which we have studied the colon bacillus is the most important pathogenic organism in a large proportion of the cases. In nearly every instance, however, we have found *more than one strain of this bacillus* to be present—either in the abscess, peritoneal exudate, or elsewhere. This fact is very important, as the various strains of the bacillus coli isolated in each case have not the same pathogenic virulence. We have found that when this organism is present in the interior of the vermiform appendix in an interval case, although the acute illness may have been some weeks previously, yet the bacillus coli will [illegible] ly as a [illegible] cavity [illegible] om this [illegible] omy in the quiescent period the colon bacillus is allowed to escape into the peritoneal cavity probably fatal peritonitis will ensue in an exactly similar manner as if the operation had been done during the acute attack. In one instance we isolated a virulent strain of the colon bacillus from a very small abscess situated in the wall of the appendix just beneath the peritoneal coat. There had not been any acute symptoms in this case for eight weeks [illegible] yet the peritoneum might e[illegible]

Everyone who has studi[illegible] must have been struck with t[illegible] pyocyaneus has been isolated from a case of appendicitis or, in fact, any case of peritonitis, the colon bacillus has been absent. We have performed a large number of experiments which show that the colon bacillus will not grow in the presence of the bacillus pyocyaneus. If both organisms are inoculated into an animal we only recover the bacillus pyocyaneus. Exactly similar results are obtained when we attempt to isolate the bacillus coli after it has been inoculated into a tube of bacillus pyocyaneus. These experiments are fully described elsewhere, but it is important to refer to them here as it is still further proof that the colon bacillus not only does not outgrow every other organism but that it cannot even exist in the presence of the bacillus pyocyaneus.

The colon bacillus appears to be less virulent than the bacillus pyocyaneus when present in the peritoneal cavity *in peritonitis and is certainly much less virulent than* the streptococcus pyogenes. If present alone in the peritoneal exudate "at a distance" then the prognosis is extremely grave, while if the phagocytes are all degenerated then the prognosis is practically hopeless. If this organism is present together with the staphylococcus albus then the prognosis is less grave, although still very bad; if, however, the staphylococcus albus has been present in the peritoneal exudate some hours before the colon bacillus then a patient suffering from diffuse peritonitis has a far better chance of recovery. We have only given a few of the chief points concerning the relations of the colon bacillus to peritonitis, as a detailed account of our work will be given elsewhere.

POST-OPERATIVE PERITONITIS.

If the literature of the bacteriology of peritonitis as a whole is scanty, that of this particular form is, for obvious reasons, still more so. Excluding most of the cases in which the bacteriological examination has been made post mortem as being of little value, we are reduced to the few instances in which the examination has been made from material *obtained at a second operation.* In 1895 Cullen investigated four cases of fatal post-operative peritonitis but, unfortunately, all post mortem. The operations were all pelvic ones and proved fatal—two on the third day, one on the sixth, and one on the eighth. The organisms isolated were, in one case, the streptococcus pyogenes and the colon bacillus; in another the staphylococcus aureus and the bacillus pyocyaneus; in the third the staphylococcus aureus; and in the fourth the staphylococci aureus and albus. It should be noted that the cases in which the streptococcus pyogenes, the bacillus coli, and the bacillus pyocyaneus were found were the most rapidly fatal. These cases, occurring within a short interval of one another in the practice of one operator, were attributed to defective catgut. It is, however, difficult to believe that catgut which had undergone any sort of cleansing whatsoever could contain all these virulent organisms, and the fact that the material was obtained post mortem detracts from the value of the observation, but we are of opinion that these cases are really of the same class as one of hysterectomy in our series in which the bacillus pyocyaneus was found and which will again be referred to. Manahan in 1903, investigating 19 cases of peritonitis from various causes, examined only one post-operative case ante mortem. This was a case of enterectomy for carcinoma where the abdomen was reopened on the third day for peritonitis. Both films and cultures from the exudate showed the streptococcus pyogenes and the colon bacillus. We have examined seven instances, six from material obtained at a second operation and one within four hours of death. Of these cases, two were local intraperitoneal abscesses and the rest were instances of diffuse peritonitis.

Two cases of appendicectomy during a quiet interval.—The first concerned a man, 31 years of age, *who had had two* attacks of appendicitis, one seven months and one three weeks before admission. The appendix was removed 15 days after admission. *At this time no swelling could be felt,* the pulse and the temperature were normal, and the patient felt in perfect health. There were some vascular adhesions and a little cheesy material about the appendix which was strictured and contained a concretion. The appendix was removed by the clamp method—that is, without opening its lumen—and the abdomen was closed. On the same evening the pulse was 108 and the temperature was 100·2° F. 12 hours later the pulse was 112 and the temperature was 100·4° and at midday on the second day they were respectively 132 and 101°. The abdomen was now rigid [illegible] percussion note over the right [illegible] nited frequently *and looked very* [illegible] operation the abdomen was re-[illegible] universal redness and distension of the intestines was found, whilst turbid odourless fluid bathed them everywhere and flakes of lymph lay amongst the coils. The inflammation was most intense in the cæcal region. There was no leakage from the buried stump. The abdomen was washed out and drained and intravenous saline infusion was performed, but death took place 44 hours after the first operation. Films of the exudate showed enormous numbers of the polynuclear cells, streptococci, and diplococci. Cultures from near the cæcum and at a distance both gave a pure growth of the streptococcus pyogenes; anaerobic cultures remained sterile. Ten cubic centimetres of the blood taken from the basilic vein at the operation gave a pure growth of the streptococcus pyogenes.

The second case occurred in a boy, 12 years of age, who had had an appendix abscess drained two months previously. He returned from a convalescent home in perfect health and with the wound healed. The appendix was found free from adhesions but strictured and exhibiting the scar of an old perforation. It was removed by the clamp method and the abdomen was closed. The peritoneum appeared perfectly healthy and cultures taken from its surface proved sterile. Within a few hours the boy became extremely ill and soon showed signs of diffuse peritonitis which became worse with extraordinary rapidity. Death occurred 40 hours after the operation. Films and cultures were taken within four hours of death. The films showed endothelial cells only and no organisms. Cultures from the exudate and from the surface of the gut gave a pure growth of the streptococcus pyogenes. Unfortunately the blood was not examined in this case.

The strain of the streptococcus pyogenes obtained from the peritoneal cavity in the first case presented the typical cultural characters of this coccus. It formed very long chains when grown in broth and stained well by Gram's method. The organism did not, however, grow anaerobically. This is, of course, an exception to the general rule in the life-history of the pyogenic cocci. This streptococcus was injected into the peritoneal cavity of a mouse and proved to be highly pathogenic. The organism was recovered from the spleen of the animal and was present in scrapings of this organ in very large numbers. The strain of the streptococcus pyogenes, which was isolated from the basilic vein, was found to be similar in every detail to the organism which had been isolated from the peritoneal cavity in the same case.

It will be noticed that there were no organisms seen in the peritoneal exudate of the second case of streptococcic peritonitis. The streptococcus which was isolated in this instance was similar in most respects to the organism which had been obtained from the peritoneal exudate and from the patient's blood in the first case, but with these exceptions, namely, that this coccus was a facultative anaerobe and that it was found to be non-pathogenic to mice. It has now been frequently demonstrated that a streptococcus which has been proved to be highly pathogenic to man may yet fail to produce any effect in animals and this is well illustrated by the instance which we have just quoted. In the first of these examples the streptococcus which was highly pathogenic to mice failed to kill a rabbit or even to have any pathogenic properties. These facts are very important when we come to consider that one of the first antistreptococcic sera to be placed on the market was obtained from a strain of the streptococcus pyogenes which had been isolated from one of the lower animals, not from a human source.

The film preparations of the peritoneal exudate which were examined in both instances serve to illustrate one very important point—viz., that the cells in the peritoneal cavity were found to be apparently healthy. It is true that in the second case we did not find any organisms but in the first case large numbers of streptococci were present. If, however, we examine the cells present in the peritoneal cavity in a case of peritonitis due to the colon bacillus both the polynuclear and mononuclear cells are always found to be degenerated. There may be some of the cells in a healthy state of preservation but the large majority are degenerated beyond recognition. This fact cannot fail to be of importance; we know that the body cells are actively phagocytic in cases of peritonitis due to the colon bacillus but only slightly so in those instances which are due to infections with the streptococcus pyogenes. It may be partly owing to this fact that in those cases of peritonitis due to the streptococcus pyogenes death occurs so very rapidly, much more so than in the case of any other known micro-organism.

With the colon bacillus free in the peritoneal cavity the prognosis is sufficiently bad, but with the streptococcus pyogenes it appears to be hopeless, and this in spite of the presence in one of these cases of enormous numbers of phagocytes which seem to be powerless against this virulent infection. We take the view that these cases are instances of infection at the operation, not from the stump of the appendix but from outside. If we adopted the theory of stump infection we should have to explain why the colon bacillus was not present; why two cases should have been due to an organism which is rarely found in appendicitis but which, when present, is of greater virulence than even the virulent colon bacillus; and why they should have recovered, the one from a catarrhal attack and the other from an abscess, and yet have retained within the appendix a streptococcus in such a state of virulence as to kill within 48 hours. Again, if these cases were due to a blood infection it is hardly possible that there would be the evidence of intense peritonitis so very soon after the original operation. If, however, the infection of the peritoneum is the primary lesion and the blood infection is secondary, as we suggest, then we have an explanation of what, to our mind, probably occurs in many fatal cases of peritonitis.

The bacillus pyocyaneus in post-operative peritonitis.—In a case of hysterectomy death was due to diffuse peritonitis caused by the bacillus pyocyaneus. Supravaginal amputation for fibromyomata had been done and the after progress was satisfactory for three days, after which the temperature began to rise and by the twentieth day there was a definite localised pelvic abscess. This was opened through the peritoneal cavity; its walls were formed partly by inflamed and distended intestine. The pus, which was thick and non-smelling, showed polynuclear cells, Gram-positive cocci and bacilli, and Gram negative bacilli. The clear fluid present in the peritoneal cavity beyond the abscess proved to be sterile, whilst the pus gave, both aerobically and anaerobically, a pure growth of the bacillus pyocyaneus. Death from diffuse peritonitis occurred eight days after the second operation. The necropsy showed universal purulent peritonitis. Ten cubic centimetres of blood taken from the basilic vein shortly before death grew the streptococcus pyogenes and the staphylococcus albus. In this instance the fatal infection of the peritoneum doubtless occurred by the opening of the abscess. Where the bacillus pyocyaneus came from in the first instance is doubtful. Possibly it was from the interior of the uterus but more probably it came from the inflamed intestine which formed part of the wall of the abscess. The absence of the colon bacillus is accounted for by its cultural relationship with the bacillus pyocyaneus, which has already been explained. In another instance the colon bacillus was found in a localised abscess after colotomy for acute obstruction. Death occurred from diffuse peritonitis.

We have three examples of staphylococcus infection. One patient had had gangrenous omentum removed from a strangulated hernia three weeks previously. The wound had been drained, had suppurated, and had healed. A localised intraperitoneal abscess around the omental stump yielded the staphylococcus albus, aureus, and citreus. The patient recovered. In another instance a large localised intraperitoneal abscess formed 14 days after myomectomy. The pus yielded a pure culture of the staphylococcus aureus and the patient recovered. In another case enucleation of a necrotic uterine fibromyoma was followed 14 days later by signs of diffuse peritonitis. The lower part of the abdomen contained a fibrino-purulent exudate from which the staphylococcus albus was obtained in pure culture both aerobically and anaerobically, whilst the films showed cocci only. The abdomen was washed out and drained. Death occurred three days later and at the necropsy it was found that the peritonitis involved only the lower half of the abdomen.

SEPTICÆMIC PERITONITIS.

We apply the term septicæmic to those cases in which the peritoneal infection is a secondary event and due to organisms brought by the blood stream. Although there is no absolute proof we consider that there is sufficient evidence to justify a belief in this manner of infection. There is little doubt that pneumococcic peritonitis is most frequently an infection by means of the blood stream, as Dudgeon and Branson have shown to be the case in most pneumococcic infections in children.

Streptococcic peritonitis.—Of this variety of septicæmic peritonitis we have examined two cases. The first instance occurred in a child aged seven months who was admitted for diffuse erysipelas. The whole cutaneous surface was at one time or another involved. On the tenth day of the illness the symptoms and physical signs of peritonitis appeared from which the child died within 24 hours.

Experiment 1.—One and a half cubic centimetres of a 24 hours' broth culture of the staphylococcus albus were injected into the peritoneal cavity of a guinea-pig; the animal was killed and the peritoneal fluid was examined 24 hours later.

Fresh drop of peritoneal fluid.—Enormous numbers of phagocytes. Very small amount of free fluid. No signs of peritonitis to the naked eye.

Film Preparations of the Peritoneal Fluid Stained by Leishman's Method.

	Total number.	Percentage.		
[illegible]	424	84·8		
[illegible]	1	0 2	73	14 6
[illegible]	72	14·4		
Large hyaline cells	1	0 2		
Eosinophiles	1	0·2		
Transitional cells	1	0·2		
	500	100·0		

The finely granular polynuclear cells in the guinea-pig's blood correspond to the polynuclear neutrophiles in human blood and are similar cells except that the granules in the guinea-pig's blood are eosinophilic. Most of the large mononuclear cells were vacuolated, most of the polynuclear cells were degenerated, while all these cells and the large mononuclear cells were phagocytic. Numerous endothelial cells were present in the film preparations but they were not included in the differential count.

Experiment 2.—One and a half cubic centimetres of a 24 hours' broth culture of the staphylococcus albus were injected into the peritoneal cavity of a guinea-pig. The animal was killed 15 minutes later and the peritoneal fluid was examined. A large amount of perfectly clear fluid was present in the peritoneal cavity. A hanging drop of the peritoneal fluid showed large numbers of leucocytes which were apparently phagocytic.

Film Preparations of the Peritoneal Fluid Stained by Leishman's Method.

	Total number.	Percentage.
Finely granular polynuclear cells	8	2·0
Small mononuclear cells	103	25 75
Large mononuclear cells	75	18 75
Coarsely granular eosinophiles	*214*	*53·5*

No less than *131* of the coarsely granular eosinophilic cells were phagocytic while many of these cells contained numerous cocci.

Experiment 3.—One and a half cubic centimetres of a 24 hours' broth culture of the staphylococcus albus were injected into the peritoneal cavity of a guinea-pig. The animal was killed an hour later and the peritoneal cavity was examined immediately after death. A large amount of clear fluid was present. No signs of peritonitis were visible. A hanging drop of the peritoneal fluid showed large numbers of leucocytes, many more than were present in a drop of the fluid from the guinea-pig's peritoneum in Experiment 2.

Film Preparations of the Peritoneal Fluid Stained by Leishman's Method.

	Total number.	Percentage.
Finely granular polynuclear cells	2	0 5
Small mononuclear cells	345	86 25
Large mononuclear cells	50	12·5
Coarsely granular cosinophiles	3	0 75

Every variety of cell was phagocytic.

Experiment 4.—The animal (guinea-pig) was killed two hours after an exactly similar proceeding as occurred in the previous experiments. Much more fluid was present than in the case of the preceding experiment. The peritoneal fluid was found to be slightly turbid. A hanging drop of this peritoneal fluid showed large numbers of leucocytes

Film Preparations of the Peritoneal Fluid Stained by Leishman's Method.

	Total number.	Percentage.
Finely granular polynuclear cells	458	91 6
Small mononuclear cells	22	4 4
Large mononuclear cells	1	0 2
Coarsely granular eosinophiles	19	3 8

Nearly every finely granular polynuclear cell was found to be phagocytic, while eight of the coarsely granular eosinophiles were also phagocytic.

Experiment 5.—A guinea-pig was killed one hour after a [illegible] (half a cubic centimetre) of the colon [illegible] as hardly any peritoneal fluid present. [illegible] of the peritoneal exudate showed large numbers of leucocytes which were apparently phagocytic. In this case the phagocytic reaction was extremely well marked but every cell was *degenerated* beyond recognition.

Experiment 6.—A guinea-pig was killed four hours after an injection of a similar dose of the colon bacillus as in the preceding experiment but another strain of the bacillus was used. The peritoneum was injected in this case and a good deal of peritoneal fluid was present.

Film Preparations of the Peritoneal Fluid Stained by Leishman's Method.

	Total number.	Percentage.
Finely granular polynuclear cells	245	61 25
Small mononuclear cells	53	12 25
Large mononuclear cells	21	5·25
Mast cells	11	2 75
Coarsely granular eosinophiles	70	17 5

28 of the eosinophiles were phagocytic as were eight of the small mononuclear cells. Every finely granular polynuclear cell was phagocytic but all were degenerated.

Experiment 7.—This animal was killed 15 minutes after receiving an intraperitoneal injection (one and a half cubic centimetres) of a 24 hours' broth culture of the staphylococcus albus. The peritoneal fluid, which was examined immediately after death, was found to be in large amount and quite clear. There was no evidence of peritonitis. A hanging-drop preparation of the peritoneal fluid showed a large number of cells which were apparently phagocytic. We did not observe any extracellular cocci.

[illegible]lear cells	0	0 0
[illegible]	293	73 25
[illegible]	14	3 5
[illegible]philes	93	23 25

We found that 48 of the coarsely granular eosinophiles were phagocytic. Many of the lymphocytes, both small and large, and the large hyaline cells were also found to be phagocytic.

As a result of these few experiments on phagocytosis we have been able to show that many of the leucocytes which are present in normal blood play a very important part in peritoneal infections. It is impossible to form any absolute conclusions from so few experiments but it is quite evident that while the staphylococcus albus provokes an extensive phagocytosis within a period of 15 minutes of injecting the organism into the peritoneum, as time advances the cells increase in number and instead of the mononuclear cells and the coarsely granular eosinophiles being the chief phagocytes the polynuclear cells with fine eosinophilic granules play the chief part in the protection of the body. The phagocytes, however, in the case of the staphylococcus albus are in good condition after many hours of warfare with the micro-organisms, but the colon bacillus may cause a very rapid degeneration of leucocytes within one hour of peritoneal infection; in every instance the colon bacillus provokes a rapid and extensive phagocytosis, almost entirely of the finely granular polynuclear variety. This bacillus, however, causes a rapid and extensive degeneration of the leucocytes, a circumstance which is not repeated in the case of the white coccus until a great many hours have elapsed.

We are now in a position to realise the harm that may be done when the peritoneal cavity is washed out in cases of peritonitis, more especially in those instances in which there is a staphylococcus infection of the peritoneum, beyond the limits of the virulent colon bacillus. If we wash away the phagocytes from the peritoneal cavity with large quantities of saline solution we allow many micro-organisms to remain in the peritoneal cavity, to say nothing of carrying the colon bacillus into fresh regions of the peritoneum, and we replace the cells and body fluids which are actively engaged in the defence of the body against their powerful opponents with a much less valuable fluid.

We have only one more point to which we wish to draw attention—namely, the phagocytic properties of the eosinophile (coarsely granular) and the small lymphocyte. We were most careful in these experiments to avoid drawing the cover-slip over the surface of the omentum; we only used the free fluid in the peritoneal cavity. There can no longer be any doubt not only that the small lymphocyte is a phagocyte but that the eosinophile possesses phagocytic properties of the very greatest importance.

ERRATUM.—In the first lecture, published in THE LANCET last week, a misprint occurs. The top line of the right-hand column of p. 479 reads: "Within a period of 30 minutes with a dilution of 1 in 150," &c. As the context shows it should have read: "Within a period of 30 minutes with a dilution of 1 in 50," &c.

testines were bathed in a large quantity of turbid but non-offensive fluid. There was no attempt at agglutination of the intestines. Film preparations of the peritoneal exudate showed large numbers of polynuclear cells which were in an apparently healthy condition, and also large numbers of diplococci and streptococci which stained by Gram's method. Many of the leucocytes were phagocytic but we did not observe one single chain of cocci within the cells, only diplococci. No other micro-organisms were seen. A culture of the streptococcus pyogenes was obtained from the peritoneal exudate and also of the colon bacillus. There [illegible] int for [illegible] le that [illegible] vity as [illegible] agony. [illegible] This patient had been ill with acute abdominal symptoms for 24 hours before the operation. A large quantity of clear exudate was found in the peritoneal cavity and an acutely inflamed mass covered with flakes of lymph in the great omen[illegible] whic[illegible] appe[illegible] The [illegible]

Large numbers of polynuclear and mononuclear cells were present in the cover-slip preparations of the peritoneal exudate but no micro-organisms. The fluid in the peritoneal cavity was found to be sterile but the staphylococci albus and aureus were obtained from the exudate near the inflamed sarcoma. A pure culture of the streptococcus pyogenes was grown from the surface of the tumour. It is very interesting to observe that although the streptococcus pyogenes was present on the surface of the tumour we failed to isolate this organism from the peritoneal exudate. Although there were large numbers of polynuclear cells in both these examples of streptococcic peritonitis, yet these cells were apparently normal and in neither instance contained any chains of cocci. We have already drawn attention to this peculiar behaviour of the cells in this variety of peritonitis, which is quite different from what is found in cases where the infection is due to the colon bacillus or to the bacillus pyocyaneus.

We consider that peritonitis due to the streptococcus pyogenes is generally a septicæmia. It would appear that in cases of peritonitis due to this organism there is hardly any local reaction at the seat of infection, such as always occurs in peritonitis due to the colon bacillus, bacillus pyocyaneus, and staphylococcus aureus. The streptococcus pyogenes is absorbed from the peritoneal cavity with such rapidity that the patient [illegible] fluids are able to offer an[illegible] We shall only obtain [illegible] ment of this disease when a valuable multivalent anti-streptococcic serum is discovered. It is extremely doubtful if more favourable results will ever be attained by surgical interference.

Pneumococcic peritonitis.—It is impossible to be certain of the origin of many cases of pneumococcic peritonitis but it is highly probable that in the large majority of cases it is a blood infection. There is no doubt, at any rate, that this statement is true as regards this variety of peritonitis in children. There is one point, however, which still requires explanation—namely, how it is that the peritoneum is so much less frequently infected with this organism than the other serous sacs. Some observers have found the pneumococcus in the peritoneal cavity in cases of pleuritis without any evidence of inflammation of the peritoneum. If we study the literature of peritonitis we find that the pneumococcus, like the streptococcus pyogenes, is frequently stated to be present without sufficient evidence. In 1886 Cornil described pneumococcic peritonitis for the first time and since that paper was published the subject has been very exhaustively dealt with, both in this country and abroad, but chiefly by French bacteriologists.

Our own series includes, in addition to one instance in which the pneumococcus was found in an appendix abscess, but not in pure culture, three instances of pure pneumococcic infection of the peritoneum. One case was operated upon; in the other two the exudate was examined within 20 minutes of death. The first example occurred in a male child, aged seven weeks, who had been ill for two days. There was œdema of the abdominal wall on admission to the tion was done and the child died on the third day of the illness. At the necropsy a large quantity of greenish fluid was found in which were suspended flakes of fibrin. A pure culture of the pneumococcus was obtained from this exudate. We failed, however, to find a source of infection.

The second case concerned a rickety male child, aged two and a half years. At the necropsy, in addition to the peritonitis which was diffuse but not of a very severe type, broncho-pneumonia, empyema, suppurative pericarditis, and lymphadenitis of the mediastinal glands were found. The peritoneal exudate was thick greenish-yellow pus. A pure culture of the pneumococcus was obtained from the pleura, pericardium, and from the surface of the lungs, but the peritoneal exudate was sterile. This example might be described as an instance of acute polyserositis.

The third case was one of extreme interest. It has been stated by certain continental surgeons that if in a child [illegible] sufficient proof that such a statement will not hold in every case. A little girl, aged six years, was seized whilst at school with acute abdominal pain. The bowels were opened four times that day. [illegible] morning and continue[illegible] admission she looked [illegible] the temperature was 10[illegible] before the operation. [illegible] tion and was not distended but was very tender on palpation. The lungs appeared to be normal. There were no signs of otitis or meningitis. The abdomen was opened 48 hours after the first symptoms had been observed. A small quantity of thin, odourless pus was present in which strings of fibrin were suspended. The intestines were reddened but not distended and the peritonitis was distinctly more marked in the lower half. The appendix was normal and the Fallopian tubes did not appear to be more inflamed than the rest of the pelvic peritoneum. The abdominal cavity was flushed out with hot saline solution and closed. Death occurred two hours later. At the necropsy the lungs were found to be normal as also were the rest of the structures above the diaphragm. The meninges were normal. Besides the condition of diffuse peritonitis which was present the uterus was found to contain about a drachm of pus.

Bacteriology.—Film preparations of the vaginal secretion taken before the operation showed large numbers of cocci and diplococci which failed to retain Gram's stain. The diplococci were chiefly intracellular but also extracellular. The ends of the cocci were flattened and these ends were approximated. Enormous numbers of polynuclear and mononuclear cells were present in cover-slip preparations of the peritoneal exudate. Large numbers of Gram-positive diplococci were also seen. These cocci were entirely extracellular. Exactly similar results were obtained with film preparations of the pus from the interior of the uterus, except that in this instance short chains of cocci were also present. A pure culture of the pneumococcus was obtained from the peritoneal cavity and from the interior of the uterus. This organism was intensely pathogenic to mice. A capsulated diplococcus was obtained from the various viscera and blood of the infected mice. This case is, therefore, of exceptional interest. It is, as far as we know, the first instance in which the pneumococcus has been isolated from a case of pyometra. Whether the abscess in the cavity of the uterus was the primary focus it is impossible to say, but it is not unlikely. A primary focus will be found in most cases of pneumococcic infections in children, however, if the *middle ears* are carefully examined. None of the cells in the peritoneal exudate in this case were degenerated, although the pneumococcus appeared to be extremely virulent. We know, however, that in the less acute cases of pneumococcic peritonitis the leucocytes are actively phagocytic. It is possible that the organism which was found in the vaginal exudate was the gonococcus, while the organism which produced the most important changes elsewhere was the pneumococcus. There were certain points as regards the morphology of the organism which were unlike the gonococcus but these are not as important as the fact that the organism did not [illegible] method and was confined to the interior of

Experiment 1.—One and a half cubic centimetres of a 24 hours' broth culture of the staphylococcus albus were injected into the peritoneal cavity of a guinea-pig; the animal was killed and the peritoneal fluid was examined 24 hours later.

Fresh drop of peritoneal fluid.—Enormous numbers of phagocytes. Very small amount of free fluid. No signs of peritonitis to the naked eye.

The finely granular polynuclear cells in the guinea-pig's blood correspond to the polynuclear neutrophiles in human blood and are similar cells except that the granules in the guinea-pig's blood are eosinophilic. Most of the large mononuclear cells were vacuolated, most of the polynuclear cells were degenerated, while all these cells and the large mononuclear cells were phagocytic. Numerous endothelial cells were present in the film preparations but they were not included in the differential count.

Experiment 2.—One and a half cubic centimetres of a 24 hours' broth culture of the staphylococcus albus were injected into the peritoneal cavity of a guinea-pig. The animal was killed 15 minutes later and the peritoneal fluid was examined. A large amount of perfectly clear fluid was present in the peritoneal cavity. A hanging drop of the peritoneal fluid showed large numbers of leucocytes which were apparently phagocytic.

extremity. A very narrow pedicle is worse than useless unless it contains the artery and vein supplying the rest of the flap. If a very narrow pedicle be altogether divided one at all events gets a free flap not dragged upon by the part supplying it.

[illegible] the blood- [illegible] by Figs. 7, [illegible] he dorsalis pedis artery, and, in part, the os calcis were destroyed, amputation was done just above the ankle-joint. The flap, shown in Fig. 7, was so cut that it consisted of a skinless pedicle, P, containing the plantar vessels and nerves, while the rest of it, B, was covered with skin and came from the ball of the foot close to the toes. For a month or two the doubled-up raw pedicle formed an ugly protuberance (Fig. 8) but this rapidly wasted and finally the stump could only be distinguished from a "Syme" by the completeness of the circle formed by the linear cicatrix. (See Fig. 9.) This case was reported in the *Annals of Surgery*, vol. viii., p. 440. Date of operation, April 2nd, 1888.

After amputating the breast and removing skin freely one [illegible] bare of skin [illegible] together as [illegible] t be taken generally from that region of loose skin, the axilla. If the raw surface is near the axilla a pedicled flap may be used. If it is near the sternum, as much as from six to ten square inches, or even more, can be cut entirely free from its original site and transferred, more or less successfully, to the inner side of the breast. Part of such a flap may perish but enough usually survives for one's purpose. Towards the end of this lecture I will try to describe how to do this operation. (See Fig. 19.)

In dealing with cicatricial contractions such as follow burns and scalds, to obtain the best cosmetic results, it is required to remove the cicatrices altogether, not simply to divide them. (See Fig. 10.) The large wound thus made has then a base and edges of normal tissue, which can be completely fitted with sound and elastic natural skin. Soft, white, and thick skin placed as a patch in the middle of a tense, thin, bluish, puckered cicatrix forms a contrast which itself amounts to a disfigurement. This should be particularly borne in mind in dealing with the face and the hands. In treating cicatricial contraction of more concealed parts, such as the popliteal space, one need not be so careful to remove the scar tissue, but it should at least be cut in two down to its base and the parts widely separated. (See Fig. 1.)

FIG. 10.

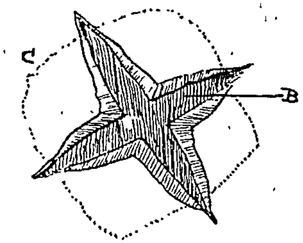

Fig. 10 represents a cicatrix to be removed. It may be [illegible]

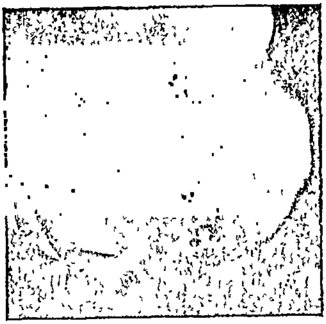
Thiersch's grafts are of limited value as a means of permanently preventing cicatricial contraction. The whole thickness of the skin is more effective. And even when the whole thickness of the [illegible] to prevent a certain amou[illegible] I think it occurs in the [illegible] of union between the two surfaces is completely organised. Hence, if one takes a case of syndactyly, divides the web [illegible] e web with Thiersch's grafts, [illegible] be so marked as to nullify [illegible] uses Wolfe's grafts it will be less. But even if one attaches the hand to the flank and uses a pedicled flap an elementary web will return. It is advisable that the fingers should be split half an inch higher than the natural web. Suturing the skin of the dorsum to the skin of the palm at the apex of the separation is totally inefficient of itself to prevent the defect under consideration. It is the contraction in a longitudinal direction between the roots and the tips of the fingers which does the mischief.

Subcutaneous fat is essential for the best result in certain circumstances, especially where free mobility is required. The deep fascia beneath it is to be spared if possible, but should a little of it be accidentally taken away no great harm seems to result.

FIG. 11.



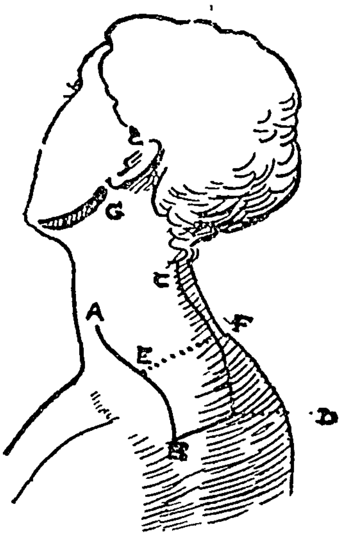
A penis covered with skin taken from the scrotum.

I have already mentioned what a storehouse of spare skin is to be found in the axilla, a happy circumstance in relation to modern operations for cancer of the breast. Another similar storehouse is the scrotum and, in a minor degree, the prepuce. The scalp has been "papered" with prepuces, in at least one case, I am told, the female scalp. The skin of the penis having sloughed in a case of extravasation of urine the dorsum of the penis adhered tightly to the front of the pubes. This not only made urination difficult and sexual intercourse impossible but also the patient was the subject of an old stricture and, with the penis fixed against the pubes, it was next to impossible to pass a bougie. To form a new skin for the penis a flap was taken from the scrotum (see Fig. 11). The patient was under the care of Dr. Richard F. Starkie.

[illegible]—I have many times at the [illegible] private performed and demon- [illegible] ion for hypospadias which I devised and first practised successfully on May 18th, 1895, assisted by Mr. R. W. Lloyd and Mr. H. G. Wharry, in a case under the care of Dr. John Duncan of St. Petersburg, after several operations had been practised unsuccessfully in that city. 1. A suprapubic drain is placed in the bladder. 2. Two rectangular skin flaps having broad bases towards the median line and on the under surface of the penis are reflected inwards. When united these two form a lining for the new urethra and their raw surfaces are outwards. 3. To cover these raw surfaces a square flap is cut from the prepuce in the following manner. The prepuce on the dorsal aspect of the penis is unfolded and everted. Then a quadrangular flap is cut through that skin layer of it which is next the glans penis, the distal border of the flap being placed near the corona glandis. This flap is turned up from the superficial layer of preputial skin. The result, of course, is a raw surface of twice the size of the flap marked out to begin with. A small longitudinal "button-hole" is cut in this dorsal part of the prepuce, close to the corona glandis and the glans penis is passed like a button through this "button-hole." The preputial flap then falls over the raw surfaces of the under flaps which were cut to begin with and is sutured in position. 4. When a week has elapsed the preputial flap is cut free from its base and any point of leakage is looked for and remedied.

Notes.—A. The two first-mentioned rectangular flaps should not be quite separate near the opening of the hypospadiac urethra but should be continuous round the scrotal margin

FIG. 3.



In this case (in the West London Hospital, September, 1904) the left horizontal ramus of the lower jaw was removed for epithelioma of the jaw and the side of the tongue. The flap, A, B, D, C, was turned up and passed through the incision, G, into the mouth. When it had adhered to the inside of the cheek, enough of it was cut off to turn up and to cover the wound on the side of the tongue and its depressor muscles. With a little stretching E F reached to B D, and healing was complete. The chin has not been pulled over to the left by cicatricial contraction, the mouth opens freely, and there is plenty of room for the dentist to fit an artificial jaw and teeth into. (February, 1905.)

FIG. 4.

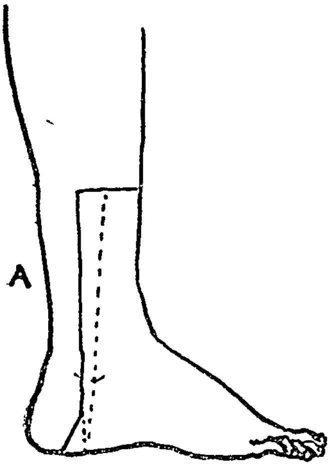


FIG. 5. FIG. 6.

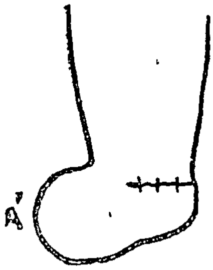

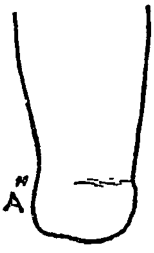

Figs. 4, 5, and 6 illustrate an amputation of the leg at the junction of the middle and lower thirds for disease of the ankle with multiple sinuses. The heel, including a part of the os calcis, was used to cover the stump. The three figures show at A, A′, and A″ how the long pedicle A gradually wastes till the stump can only be distinguished from an ordinary Syme's or Pirogoff's amputation by the shortness of the leg. I performed a similar operation on a patient under the care of Mr. Frederick Lawrance on May 26th, 1895.

the chin down to the clavicles had been burnt and replaced by a cicatrix which held the chin downwards and to one side (traumatic wry-neck). The cicatrix was excised and replaced by a flap from the right upper arm. Afterwards the arm was repaired from the chest and the thoracic wound was closed, partly by bringing its edges together and partly by Thiersch's grafts from the thigh.

Finally, whether there be two steps or only one in a given case, the last deep wound made has to be closed either by forcing its edges together or by Thiersch's grafts or partly by bringing the edges together and partly by Thiersch's grafts. For example, in the case illustrated by Fig. 3 there was, after the skin required had been cut off, enough left on the pedicle and on the back part of the root of the neck to permit the large skin wound to be closed entirely by sutures. In many cases a large wound can be sutured down to a smaller size and the remainder closed by Thiersch's grafts. An example of this has just been given in the case of cicatrix of the throat after a burn. The most convenient place for taking Thiersch's grafts from is usually the front of the thigh.

The base of a flap should be wide. An oblong flap with a base narrower than the length is apt to slough at the distal

FIG. 7.

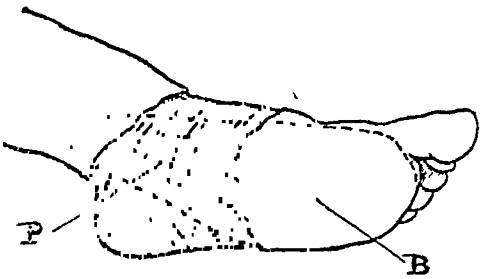

FIG. 8.

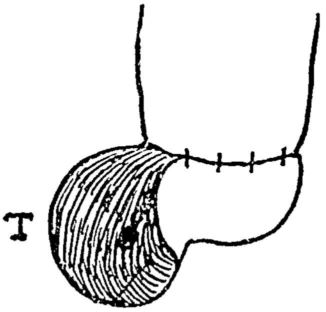

FIG. 9.

Figs. 7, 8, and 9 illustrate a case in which the skin of the heel having been de[illegible] of the sole of the foot were used to c[illegible] of the flap contained the plantar vessels and nerves. Its pedicle, which was *uncovered by skin*, at first formed a fleshy tumour T (see Fig. 8) but in a few months the stump could only be distinguished from a Syme by the linear cicatrix which formed a complete circle.

THE VALUE OF THIERSCH'S GRAFTS IN THE TREATMENT OF BONE AND JOINT DISEASE.

Six years ago I had to treat a curious case of ulcer of the leg. At first this may have originated in varicose veins from which the patient, a middle-aged man, suffered severely, but the diseased process had penetrated the upper end and also the middle of the shaft of the tibia very deeply. The surrounding skin was blue and the fat as soft as ground rice. A blunt spoon easily scraped away large quantities of diseased skin, fat, and disintegrated bone. I cut away every obviously unsound portion of hard and soft tissue, leaving an apparently healthy surface. The result was two long cavities in the tibia, so deep that they all but completely penetrated the bone from the shin to its posterior aspect. Experience shows that, under ordinary treatment, such cavities take months to heal and that, in the meantime, diseased processes are apt to start again in them. Accordingly, surgeons have sunk flaps of soft tissue into them to fill them up. I have tried this plan myself with fair success but it is not an ideal plan for various reasons. On this occasion I simply lined (papered as it were) the cavities with Thiersch's grafts. Healing was immediate, except at one small deep point near the bottom of the cavity in the middle of the tibia. (See Fig. 17.) At the same time I performed Trendelenburg's operation for the varicose veins in both limbs. The point which escaped the scraping and grafting afterwards formed the starting point for further mischief, like the original in character, though of not one-twentieth the extent, and led to further operations. On each of these occasions, after successfully grafting, I put the patient through a course of iodide of potassium. I was not able to determine the character of the growth microscopically. There was no syphilitic history; but the iodide did good and, of itself, healed one point which broke out afresh. The recurrence did not begin in the part grafted. Unfortunately, the patient was last summer attacked with extensive glandular enlargement in the groin. I have removed the glands; they appeared to be epitheliomatous; but at present (February, 1905) there has been no recurrence. [illegible] well and the cavities lined [illegible] a third of their original depth. Here sound bone has formed and lifted the grafted skin towards the general surface of the limb without loosening it in any way. I have performed this operation now on a number of bone cases, mostly tuberculous, and have nearly always had the same result in the way of quick healing and, except in the case first described, have had no glandular trouble.

FIG. 17.

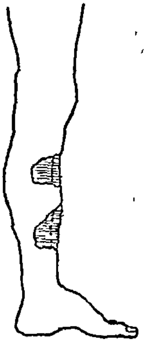

Diagram to indicate the depth of cavities in the tibia which were lined with Thiersch's grafts The straight and broken lines show the depth a year after operation

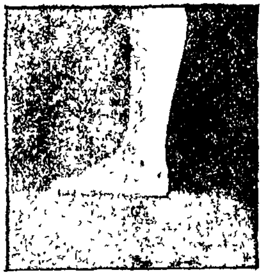
I believe it may be laid down as a law that *skin grafts have in some way a property of inhibiting the recurrence of specific ulcerations of the bones and muscles, as well as of the skin, and that this applies not only to tubercle but to epithelioma and to leprosy*. Of course, the local disease should be carefully removed first; but, locally at least, success may be expected even if the general system still remains infected. Dr. Robert J. Colenso, Dr. Robert Moir, and I treated by excision and skin-grafting an ulcer as large as the palm of the hand on the outer side of the knee of a male, with various other troubles due to leprosy contracted in the East. The result was a speedy healing, which has not broken down to this day (seven years after the operation). At the same time that I was operating in this way on the larger bones of the limbs and, as I shall show presently, on the joints also, Mr. C. A. Ballance was working independently in a similar manner on the temporal bone for the cure of middle-ear disease.

It then seemed to me that a similar method might be employed to prevent the formation of those chronic sinuses which often follow operations on diseased joints, which are so difficult to cure, and inflict so much suffering, inconvenience, and even danger on the patient. On Sept. 13th, 1900, I resected a suppurating tuberculous hip in a girl, seven years of age, at the West London Hospital. A sinus remained and in a short time not only this sinus but an area around it of the size of the palm of the hand became infiltrated with tubercle. The infiltration involved skin, subcutaneous fat, and intermuscular spaces, if not muscles. Accordingly, on Oct. 23rd I operated again, took pains to remove the disease and made a large wound, partly superficial, [illegible] to the bare bone left by the resecti[illegible]d especially the deep, [illegible]o the bone, with Thiersch's grafts which overlapped the bone. The deep part of the wound healed at once, even in a few days. The superficial part, where some of the grafts had slipped and not taken perfectly, had to be regrafted in parts. The patient was shown at the Medical Society of London on Feb. 10th, 1902.[2] I see her occasionally and in the four years she has had no recurrence of tubercle, either locally or elsewhere. I have repeated this operation on various patients, one of them a child with disease of both hips, always with ultimate success and generally with immediate success.

FIG. 18.



The leg of a young girl on whom I operated several years [illegible] the help of Mr. Sidney [illegible] Tanner Cooper. The [illegible]raped and gouged out [illegible] grafts which adhered [illegible]ng rapidly filled up, leaving mere [illegible] illustration.

Failure can easily be traced to one or other of the following causes. (1) neglecting to line the cavity in the soft tissues completely, that is, leaving a granulating and discharging surface; (2) neglecting to dress the wound at the proper time, or dressing roughly and disturbing the grafts; and (3) leaving a sequestrum or much diseased bone at the bottom of the grafted wound. These mistakes can be rectified by another operation, but it is, of course, better to avoid them.

The mode of treatment described affords an escape from the dilemma in which the drainage tube is apt to place us, the dilemma in which, if the tube is removed, a sinus refuses to heal from the bottom, while, if the tube is left, it necessarily keeps up a discharging sinus, liable to be reinfected with tubercle if not already infected. What is exceedingly striking in watching the after-course of a case of this kind is the way in which the grafted deep wound diminishes in size, not only in width but also in depth. After a few months a wound which when first grafted and of the opening, so that together they look like a flat horse-shoe magnet. Then the outer margin of this flat horse-shoe is "gathered up" by the suture. B. This suture should be single and very simple, so as to be easily removeable. There is not enough substance in such flaps to absorb catgut knots. A single piece of silkworm gut, passed in and out so as to form a figure of 8, with the ends emerging under the glans penis, suffices. C. In reflecting the transverse part of the magnet-shaped flap great care must be used because of the thinness of the floor of the urethra near the hypospadiac opening in most of these cases.

---

[2] Transactions of the Medical Society of London, vol. xxv., p. 335.

In "Heath's Dictionary of Surgery" Mr. John Wood pointed out that the prepuce could be used in operating for hypospadias but his mode of using it would be likely to fail, I think, for the following reasons: (1) he makes no suprapubic drain; (2) he cuts the preputial flap after button-holing the prepuce; (3) he makes this aperture transverse; (4) he does not unite the under flaps round the hypospadiac meatus; and (5) he does not suture after the fashion described in Note B (above). These points are essential if the operator is to expect success.

A moderate amount of skin can be taken from the trunk of even the tightest-skinned person, enough to fill up defects in the hand and fingers. Much more can be spared by older people with lax abdomens and the skin hanging in folds. Sometimes the surgeon can act on the principle that one fairly complete organ is better than two seriously incomplete, just as a poor mother might put one child to bed and send the other to school in clothes partly borrowed from his brother rather than keep both idle and half clad at home. A young woman came into the West London Hospital with all the fingers of the right hand crushed, torn, and on the palmar surface burnt by the hot roller of a machine mangle. Nearly every interphalangeal joint was open on the palmar aspect. All the flexor tendons of the middle and ring fingers were destroyed. But their dorsal tendons were intact. I therefore amputated the ring finger, preserving all its dorsal soft structures. These being then brought round and fixed to the previously refreshed palmar surface of the phalanges and joints of the middle finger, the extensors of the ring finger assumed the duties of flexors of the middle finger. The results both as regards appearance and function were surprisingly good (see Figs. 12 and 13). In Fig. 13, D marks the back of the ring finger transferred to the palmar side of the middle finger.

Other examples of the application of this principle are given by plastic amputations of the foot (see Figs. 4 to 9). A middle-aged man was taken into the West London Hospital for amputation of a leg, most of the skin of which was destroyed by a chronic ulcer. It occurred to me that if I used the soft structures of the whole sole of the foot to cover the skin I might simply excise the ulcer, amputate a little way above the ankle, cover the end of the stump with the heel-flap, and get that best of all stumps, a "Syme." (The original intention, of course, had been to amputate at, or below, the knee.) The success of the plan was perfect. The case was reported in THE LANCET of Nov. 28th, 1885, p. 987. Professor Rydigier of Cracow has [illegible] operation in exactly the same way [illegible] Syme's amputation, saying, among other things, that a longer stump can be obtained. But it must be remembered that the more the os calcis is preserved the more the tibia must be sacrificed, unless the original ulcer is almost too small to justify such an operation at all.

FIG. 12.

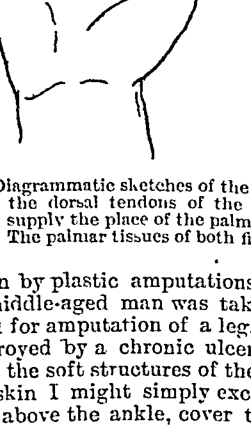


FIG. 13.

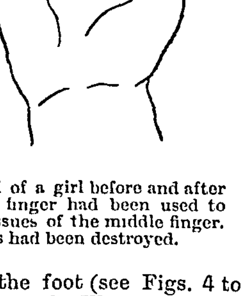

Diagrammatic sketches of the hand of a girl before and after the dorsal tendons of the ring finger had been used to supply the place of the palmar tissues of the middle finger. The palmar tissues of both fingers had been destroyed.

FIG. 14.

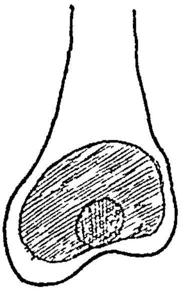

FIG. 15.

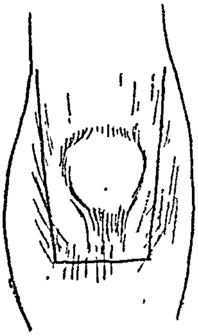

FIG. 16.

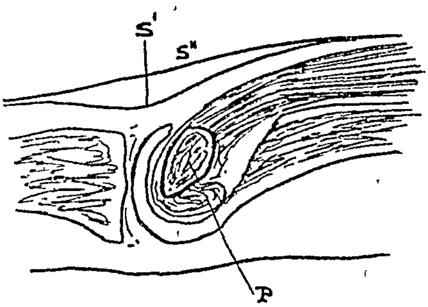

These figures illustrate the case in which the patella and surrounding tissues were used to fill up the cavity left by hollowing out the tuberculous lower end of a femur.

It should be noticed that in the last-quoted example it was not merely the skin but also the subjacent muscular and even osseous structure which were transferred. This principle can be applied in the middle of a limb as well as at its extremity. A housemaid, about 28 years of age, a patient of Dr. Johnston, late of Wentworth Fitzwilliam, had long suffered from chronic disease of one knee-joint. An operation had left fistulæ leading from each side into the centre of the condyles of the femur. These condyles had been a shell of bone filled with cheesy matter of an orange-yellow colour. After this cheesy matter was removed and the knee-joint found, though filled with fibrous adhesions and with the patella ankylosed by bone to the femur, to be free from active disease, the above-mentioned fistulæ were left. They led to the large cavity in the femur, which discharged freely and had not contracted materially in spite of packing, drainage, and much patience exercised for months. The patient's general condition was very bad. She was weak and emaciated. On Sept. 16th, 1902, the patella and the quadriceps above and around it were exposed, the ligamentum patellæ was cut through transversely, and a thick quadrangular flap of aponeurosis, muscle, and ligament containing the patella turned up so as to expose the front of the condyles. These were then completely hollowed out till the femur resembled a deep spoon. The flap was then sunk into the hollow formed by gouging and scraping the condyles. Healing was complete in a fortnight. The patient's general health improved at once. Even the day after operation her face had assumed a bright and healthy look. She has several degrees of movement and has for some time filled a housekeeper's place. (See Figs. 14, 15, and 16, in which P represents the buried patella, S′ the level of the skin immediately after operation, and S″ its level now.) In this case it was of prime importance to obtain quick healing. Prolonged granulation and suppuration in such cases generally mean not only injury to the general health but also recurrence of the disease.

THE VALUE OF THIERSCH'S GRAFTS IN THE TREATMENT OF BONE AND JOINT DISEASE.

Six years ago I had to treat a curious case of ulcer of the leg. At first this may have originated in varicose veins from which the patient, a middle-aged man, suffered severely, but the diseased process had penetrated the upper end and also the middle of the shaft of the tibia very deeply. The surrounding skin was blue and the fat as soft as ground rice. A blunt spoon easily scraped away large quantities of diseased skin, fat, and disintegrated bone. I cut away every obviously unsound portion of hard and soft tissue, leaving an apparently healthy surface. The result was two long cavities in the tibia, so deep that they all but completely penetrated the bone from the shin to its posterior aspect. Experience shows that, under ordinary treatment, such cavities take months to heal and that, in the meantime, diseased processes are apt to start again in them. Accordingly, surgeons have sunk flaps of soft tissue into them to fill them up. I have tried this plan myself with fair success but it is not an ideal plan for various reasons. On this occasion I simply lined (papered as it were) the cavities with Thiersch's grafts. Healing was immediate, except at one small deep point near the bottom of the cavity in the middle of the tibia. (See Fig. 17.) At the same time I performed Trendelenburg's operation for the varicose veins in both limbs. The point which escaped the scraping and grafting [illegible] for further mischief, lik[illegible] not one-twentieth the [illegible] On each of these occasions, after successfully grafting, I put the patient through a course of iodide of potassium. I was not able to determine the character of the growth microscopically. There was no syphilitic history; but the iodide did good and, of itself, healed one point which broke out afresh. The recurrence did not begin in the part grafted. Unfortunately, the patient was last summer attacked with extensive glandular enlargement in the groin. I have removed the glands; they appeared to be epitheliomatous; but at present (February, 1905) there has been no recurrence. The leg apparently remains quite well and the cavities lined with Thiersch's grafts are only a third of their original depth. Here sound bone has formed and lifted the grafted skin towards the general surface of the limb without loosening it in any way. I have performed this operation now on a number of bone cases, mostly tuberculous, and have nearly always had the same result in the way of quick healing and, except in the case first described, have had no glandular trouble.

FIG. 17.

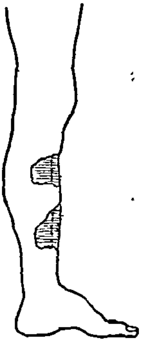

Diagram to indicate the depth of cavities in the tibia which were lined with Thiersch's grafts The straight and broken lines show the depth a year after operation.

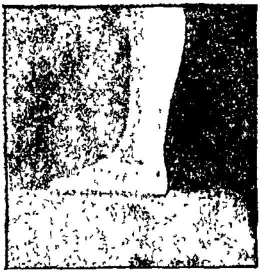
I believe it may be laid down as a law that *skin grafts have in some way a property of inhibiting the recurrence of specific ulcerations of the bones and muscles, as well as of the skin, and that this applies not only to tubercle but to epithelioma and to leprosy.* Of course, the local disease should be carefully removed first; but, locally at least, success may be expected even if the general system still remains infected. Dr. Robert J. Colenso, Dr. Robert Moir, and I treated by excision and skin-grafting an ulcer as large as the palm of the hand on the outer side of the knee of a male, with various other troubles due to leprosy contracted in the East. The result was a speedy healing, which has not broken down to this day (seven years after the operation). At the same time that I was operating in this way on the larger bones of the limbs and, as I shall show presently, on the joints also, Mr. C. A. Ballance was working independently in a similar manner on the temporal bone for the cure of middle-ear disease.

It then seemed to me that a similar method might be employed to prevent the formation of those chronic sinuses which often follow operations on diseased joints, which are so difficult to cure, and inflict so much suffering, inconvenience, and even danger on the patient. On Sept. 13th, 1900, I resected a suppurating tuberculous hip in a girl, seven years of age, at the West London Hospital. A sinus remained and in a short time not only this sinus but an area around it of the size of the palm of the hand became infiltrated with tubercle. The infiltration involved skin, subcutaneous fat, and intermuscular spaces, if not muscles. Accordingly, on Oct. 23rd I operated again, took pains to remove the disease and made a large wound, partly superficial, [illegible] bone left by the resecti[illegible]d especially the deep, [illegible]o the bone, with Thiersch's grafts which overlapped the bone. The deep part of the wound healed at once, even in a few days. The superficial part, where some of the grafts had slipped and not taken perfectly, had to be regrafted in parts. The patient was shown at the Medical Society of London on Feb. 10th, 1902.[2] I see her occasionally and in the four years she has had no recurrence of tubercle, either locally or elsewhere. I have repeated this operation on various patients, one of them a child with disease of both hips, always with ultimate success and generally with immediate success.

FIG. 18.



The leg of a young girl on whom I operated several years ago for caries of the os calcis with the help of Mr. Sidney L. Tench of Brixton and Mr. A. Tanner Cooper. The greater part of the os calcis was scraped and gouged out and the cavity lined with Thiersch's grafts which adhered at once. The large cavity resulting rapidly filled up, leaving merely the small dry depression shown in the illustration. The functional result was perfect.

Failure can easily be traced to one or other of the following causes: (1) neglecting to line the cavity in the soft tissues completely, that is, leaving a granulating and discharging surface; (2) neglecting to dress the wound at the proper time, or dressing roughly and disturbing the grafts; and (3) leaving a sequestrum or much diseased bone at the bottom of the grafted wound. These mistakes can be rectified by another operation, but it is, of course, better to avoid them.

The mode of treatment described affords an escape from the dilemma in which the drainage tube is apt to place us, the dilemma in which, if the tube is removed, a sinus refuses to heal from the bottom, while, if the tube is left, it necessarily keeps up a discharging sinus, liable to be reinfected with tubercle if not already infected. What is exceedingly striking in watching the after-course of a case of this kind is the way in which the grafted deep wound diminishes in size, not only in width but also in depth. After a few months a wound which when first grafted and for some days after reached into the hip-joint may only admit the point of a probe for about half an inch. The little sinus is quite dry and still obviously lined with Thiersch's grafts.

---

[2] Transactions of the Medical Society of London, vol. xxv., p. 335.

It is obvious that one lecture on plastic surgery of an hour's duration cannot be made exhaustive, even if one speaks only of the plastic surgery of the skin. Before concluding with a few remarks on technique I should like to refer to

TRANSPLANTING AND GRAFTING MUCOUS MEMBRANE.

Twenty years ago I inherited from my senior at the West London Hospital, that distinguished specialist in urinary surgery the late Mr. Teevan, a case of urethral stricture which was in several ways remarkable. He had had median perineal cystotomy performed several times, once to remove a foreign body, the broken off end of a catheter. The patient himself once seen could never be forgotten; his hair was of a bright orange colour with a tinge of crimson, due to his work in a colour factory. Having for the second or third time to rescue him from retention by a perineal division of a mass of cicatrix containing no traceable urethra I on the last occasion took a rectangular transplant of about one and a half inches by two inches of mucous membrane from the rectum, close to where it passes into skin. With the finest catgut I sewed this, raw surface outwards, over a No. 12 rubber catheter. I then passed the catheter through the perineal wound, half of it into the bladder and half of it through the penile urethra. After a week the catheter was removed. A careful watch was kept but no trace of the graft was ever seen again and the patient never required operation again. Some years afterwards a message came that he had been taken dangerously ill. He died almost immediately. My house surgeon, Mr. H. Scott Elliott, made a post-mortem examination under great difficulties. It was the depth of a hard winter. The body lay frozen hard throughout in a cottage. He brought home the specimen, but when examined the urethral part stopped short just behind the seat of the stricture!

I have had the opportunity of repeating this operation in a manner varied so as to enable me to see and to demonstrate the adhesion of the graft of rectal mucous membrane to the site of a resected mass of urethral granulations and cicatricial tissue. In this case I kept the perineal wound open by gauze packing until the grafts had visibly adhered.

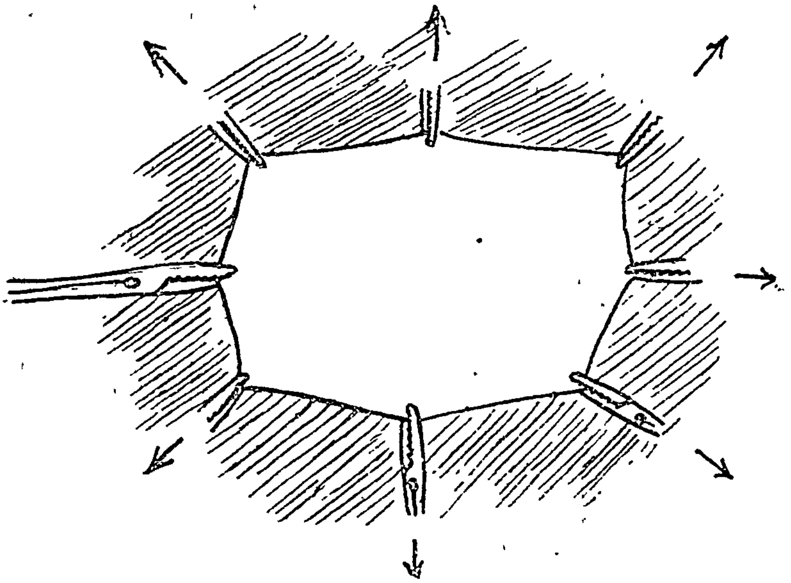
THE QUESTION OF ANTISEPTIC *v.* ASEPTIC METHODS IN PLASTIC SURGERY.

I may claim to have been one of the first to point out the desirability of keeping chemical antiseptic lotions away from grafts and using warm water instead.[3] Warm solution of common salt ("neutral saline") is an improvement on plain water. But frequently now the importance of this detail of practice is greatly exaggerated. Neither Thiersch's grafts nor flaps are seriously injured, much less killed, by contact for a short time with the lotions ordinarily used in antiseptic surgery, such, for example, as 1 in 2000 perchloride of mercury. I cut my grafts with a blade which has been boiled but with its edge protected by lint or cotton-wool. All the gauze dressings (often the swabs as well) have been wrung out of 1 in 2000 perchloride lotion. For certain reasons, more especially because it confuses nurses to change the mode of dressing with the class of operation, I find it more convenient to use this technique, although I acknowledge that salt solution is preferable in the abstract, and, indeed, I use it when any "floating" or douching is required. The knife is not blunted and the grafts are not killed.

The great enemy to successful plastic surgery is not antisepsis but sepsis. A graft bathed in pus will not adhere and live. This must be carefully remembered in the after-treatment. When one feels assured that the wound is aseptic the first dressing may be postponed for a week and the graft should be found alive and firmly fixed. But if there is danger of suppuration the dressing should be daily and a free passage for the escape of pus must be provided. This daily dressing must be done with great delicacy.

The surface to be grafted may [illegible] thinly coated with fresh, bright, and [illegible] As a rule it is best to scrape away th[illegible] urface should be prepared first and bleeding from it staunched by pressure while the grafts are being cut. But grafts have themselves a hæmostatic action. When blood is effused beneath a graft it should be pressed out with a swab and with some flat, smooth, metallic instrument placed between the swab and the graft, otherwise the swab will bring the graft away. A single layer of gauze serves as a protective. More gauze is placed on the top of it and removed independently at the next dressing. Cotton-wool should be used extravagantly to prevent rubbing and, if necessary, pads to prevent pressure. When pedicled flaps are transplanted they should be fixed (1) by sutures of the edges; (2) by supplementary and very stout sutures near but not in the base of the flaps (thick silver may be used for these); (3) by strapping; and (4) by plaster-of-Paris. Plaster-of-Paris not only tends to give a better final result but greatly prevents pain, though it sometimes gets in the way of dressing. At the separating operation a trustworthy assistant should hold the parts together—e.g., the limb to the trunk—until not so much as a hair's breadth of the pedicle remains undivided. A premature movement at this moment may do irretrievable damage. Before forming the flap a pattern of its size and shape may be cut in green protective or in boiled rubber sheeting. The patient's own blood serves for a red ink to mark out the flap. After a pedicled flap is cut free it generally requires careful readjustment and the insertion of fresh sutures.

FIG. 19



Forceps arranged round a free skin flap to take the "curl" out of it and facilitate removal of fat.

With regard to Thiersch's grafts, a concave-edged amputating knife does well for cutting them. A broad metal spatula is generally convenient for transferring them. An excellent substitute is a tablespoon. The graft should be placed in the concavity of the spoon. A much larger graft can be spread out on it than on a spatula. For lining a narrow cavity a teaspoon or eggspoon may be useful. In lining a deep cavity with grafts the point end of the knife itself may have to be used to carry the grafts in. Do the Thiersch's grafting thoroughly. Do not leave small uncovered angles and intervals.

Now with regard to *transplants of the whole thickness of the skin* transferred without any pedicle. After cutting such a graft out arrange half a dozen catch forceps around its edges. (Fig. 19.) Place it, raw surface upwards, on a sterilised towel and a convex surface, usually a part of the patient—e.g., his thighs or chest. Have the flap well stretched in every direction by pulling at the forceps Shave off all the fat Stretch the flap again (to take the elasticity and tendency to curl up out of it) Swing it into place Secure it with a few sutures But cut away all the forceps so as to leave no bruised skin behind The most rigid asepsis is desirable to insure success in this operation and the more vascular the part grafted the better of course

---

[3] Notes on Plastic Surgery, Annals of Surgery, 1887, vol. vi., p. 97.

TRANSPLANTATION BY EXCHANGE

When a large hairy mole has to be removed from the face it can be exchanged with a piece of skin of the same size and shape taken from the arm Stout sutures should anchor the mole to the arm Only very delicate sutures will then be needed to adjust the arm skin to the face [4]

I have directed attention almost entirely to the transplantation and grafting of skin and mucous membrane and of structures attached to them It is of course well known that every tissue of the body is transferable and that there is a plastic surgery of muscle tendon bone nerve, blood vessel, omentum intestine stomach liver, kidney and other deep parts which has already a large literature and concerning which much more remains to be written

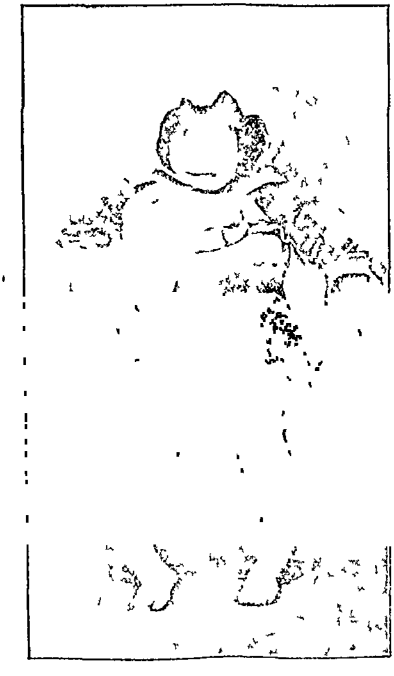
THE TREATMENT OF SEVERE CURVATURES IN THE TIBIÆ BY MEANS OF MANUAL OSTEOCLASIS

By T H OPENSHAW, C M G, M S Durh, F R C S Eng,
SURGEON TO THE LONDON HOSPITAL SENIOR SURGEON TO POPLAR ACCIDENT HOSPITAL AND SURGEON TO THE NATIONAL ORTHOPÆDIC HOSPITAL

HAVING during the past two years thoroughly tested this method of treatment I venture to bring it to the notice of the profession as a rapid permanent and complete cure of pronounced rickety curvatures in the tibiæ Of some 30 or more cases which I have treated by this method the following which I had photographed and skiagraphed both before and after treatment is a typical example

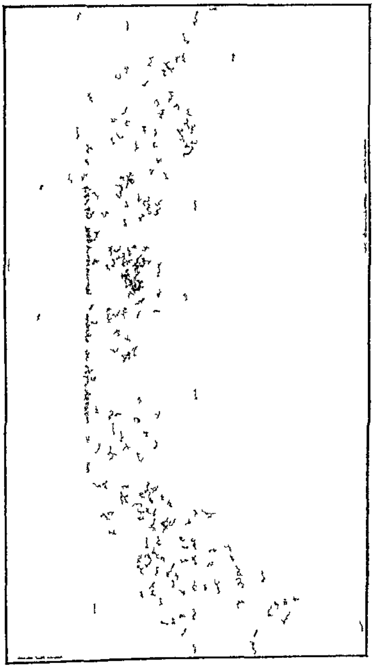
FIG 1



The patient aged four years Oct 7th 1904

A girl aged four years was brought to me at the London Hospital on Sept 9th 1904 with well marked curved tibiæ enlarged epiphyses rickety rosary, and other signs of recent rickets She had been breast fed for one year and only walked at the age of three years Fig 1 (reproduced from a photograph taken on Oct 7th) shows both tibiæ so extravagantly curved that a line continuing the anterior border of the upper two thirds of each tibia falls outside the corresponding foot Fig 2 (reproduced from a skiagraph of the leg bones taken on Oct 7th) shows the tibia so curved that the inferior surface of its lower extremity is directed inwards On Oct 20th manual osteoclasis of the left leg was performed two lateral splints were applied and the child was sent home She was brought for inspection the next day The circulation of the foot being good and no pain being complained of the splints were left undisturbed and a skiagraph of the leg (Fig 4) was taken The child was seen a week later on the 28th and the splints were re adjusted On Nov 11th the splints were removed and the child s legs were photographed in the standing position as seen in Fig 3 [illegible] left [illegible] straight the right present
before
[illegible] lly anæsthetised the leg is encased in cotton wool and bandaged The child is then turned over so that the leg which is to be broken lies on its outer side A wedge shaped block measuring some seven inches by three inches at the base and six inches high is used The upper edge of this block is about one inch wide and four inches long and is covered with thick indiarubber This block is put underneath the leg transversely at the

FIG 2

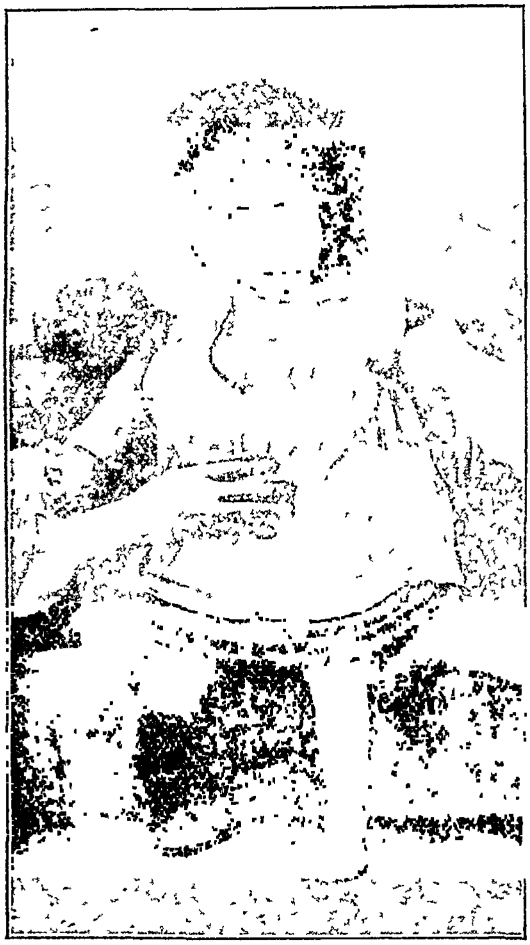


Oct 7th 1904 Reproduction of skiagraph of tibia and fibula (left) centre of the curve. The operator with one hand grasps firmly the foot and ankle and lower portion of the tibia and with the other hand the upper part of the tibia, the hands of the operator being some two to three inches apart. With the block resting quite firmly upon a firm table, and the child's leg on the rubber-covered upper edge of the block, with a steady and increasing pressure exerted through the hands of the operator, the bones of the leg are snapped across and the leg can then immediately and easily be made to assume a straight position. In a few instances the fibula can be heard to crack first but in the majority of cases the fibula is simply bent and the tibia alone is broken. In the case of some 40 legs which I have operated upon in this manner no bruising of tissue, laceration of skin, or other untoward result has occurred. The limb has been put up in two lateral well-padded wooden splints, bandaged, and the child sent home immediately on recovering from the anæsthetic.

---

[4] The Lancet Nov 22nd 1902 and Feb 19th 1887

FIG. 3

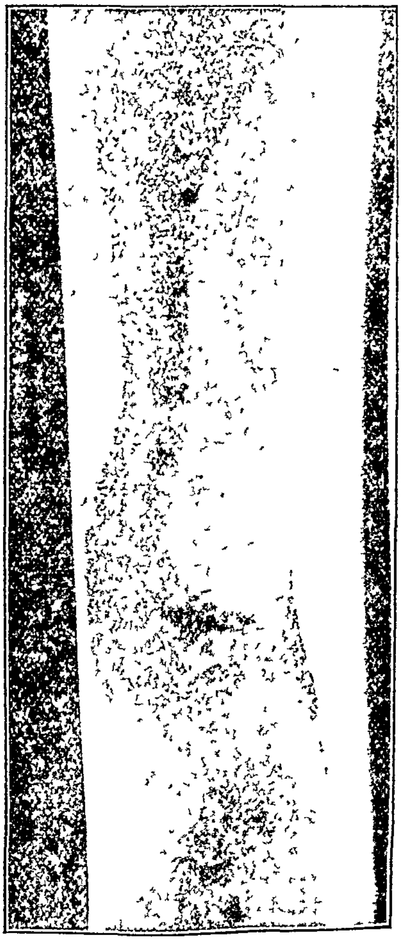


The patient Nov 11th, 1904.

The line of fracture in nearly every case is transverse, in a few it is oblique, and in a few irregular in outline. The fracture in the tibia is situated at the exact spot where it is necessary that the bone should be broken in order that the leg can be made to assume a straight position. The act of stretching the bone into a straight position puts tension upon the bone at the exact spot where it is necessary that it should be fractured. The fracture gapes and the fractured surfaces are separated to an extent just sufficient to permit the bone to become straight. This wedge-shaped separation of the fractured surfaces actually increases the length of the bone and corrects the shortening due to the curvature. The bone is lengthened proportionately to the length of the base of this wedge-shaped cleft The more the bone is curved the thicker is the wedge-shaped cleft and the greater the consequent lengthening. The periosteum on the convex side of the bone is unbroken and it is doubtful whether the periosteum on the concave side of the bone is more than lacerated and stretched.

The repair of this fracture is exceedingly rapid. I have x ray photographs showing complete obliteration of the line of fracture, in one case in six weeks after the manual osteoclasis was performed; whereas in an ordinary fracture of an adult tibia it is often possible by the x rays to make out the line of fracture some 12 months after the date of fracture. The advantage of this method of treating pronounced curvatures in the tibia as compared with the prolonged application of straight wooden splints to the inner side of the legs, or the use of complicated and expensive surgical appliances, must be obvious. It is no uncommon occurrence for splints to be worn for six or 12 months and in some cases for an apparatus to be worn for years, whereas by manual osteoclasis the patient's legs are straightened at once and the patient is made to walk about quite well with straight legs in from three to four weeks.

FIG. 4.



Reproduction of skiagraph taken on Oct. 21st, 1904, the day after manual osteoclasis.

Compared with cuneiform osteotomy, in my opinion, manual osteoclasis is far superior. In the first place, the bone is broken exactly at the spot and along the plane which is absolutely the proper one in order to allow the bone to become straight. It is impossible precisely to ascertain where this plane is situated until the bone has been broken. It is only by *straightening* the bone and allowing it to break that the proper line of fracture can be determined. Every operator knows how difficult it is to remove by cuneiform osteotomy exactly the proper-sized wedge and to remove it from exactly the correct plane in the bone. Secondly, the bone is lengthened instead of being shortened by the excision of a wedge-shaped portion. Thirdly, instead of an open wound with much damaged bone and periosteum a simple intraperiosteal greenstick fracture is produced which is firmly healed and permits the child to walk in three weeks Fourthly, the operation can be performed and the child treated as an out patient

It may be asked Is it always necessary that the bone should be broken? In my opinion it is imperative that the bone should be broken before the leg will remain straight For over a year I had under observation one child whose right leg I endeavoured to straighten by manipulation without breaking the bone but after a year s splinting and *repeated manipulations the right leg was still considerably* curved and had to be broken and straightened It is therefore in my opinion always essential that the tibia should be broken by manipulation The leg cannot otherwise be straightened On three occasions I have used this method of straightening a leg which had become deformed as the result of a fall some years after cuneiform osteotomy The eldest child so straightened was aged 12 years It is obvious that there is an age limit beyond which it is impossible to fracture the leg by manual manipulation, but in my opinion the leg of any child under ten years of age may be so broken where necessary

THE CAUSE OF PAIN IN CASES OF GASTRIC ULCER AND ITS BEARING UPON THE OPERATION OF GASTRO-JEJUNOSTOMY

BY C W MANSELL MOULLIN, F R C S ENG

SENIOR SURGEON AND LECTURER ON SURGERY AT THE LONDON HOSPITAL

THE walls of the stomach have no sensory nerves, that is to say no nerves capable of exciting that part of the nervous system which is concerned with the sensation of pain This has been proved by the method of operating under local anæsthesia They may be cut or crushed or burnt without exciting the slightest feeling And it is well known that a gastric ulcer may develop without causing pain or any other symptom until the barrier gives way and the contents of the stomach escape into the peritoneal cavity On the other hand it is no less certain that dyspepsia and gastric ulcer are usually attended by severe suffering and that not only is there pain but often great tenderness as well both deep and superficial There must be a reason for this difference and it seems to me that the reason is of some clinical significance In gastric surgery what is wanted more than anything else is greater accuracy of diagnosis and everything that can assist in diagnosis is of value

The characteristic pain of gastric ulcer comes on shortly after the food has entered the stomach grows worse and worse as digestion goes on and then gradually becomes less severe as the stomach empties itself Vomiting often relieves it at once Exceptionally it begins later and in a few rare instances it is stated that it is relieved by taking food It is clear that pain of this character is not due to contact of food with the mucous surface for it has been shown on many occasions that stimuli of this kind do not cause any sensation at all and that it is not due directly to increased acidity, for it has been proved that acids much

ame thing is true of

hat is formed in the

stomach can cause pain by contact with its walls The only way in which the act of digestion can cause pain is by the movement of the stomach affecting the sensory nerves distributed around it, and there is abundant evidence to show that this is the chief if not the sole agent Sensory nerves derived from the intercostals are distributed in abundance in the parietal peritoneum or rather in the subserous cellular tissue that underlies it The least drag upon this is instantly resented If the patient is under an anæsthetic the *heart and the respiration show* the effect at once In one instance under my care in which the walls of the stomach were peculiarly hard and rigid (leather bottle stomach) I had for this reason alone to abandon the operation I had proposed and content myself simply with an exploratory laparotomy Respiration stopped at once when the least traction was made upon the stomach If the patient is not under general anæsthesia there is an immediate complaint of pain The painless ulcer that forms almost without a symptom and suddenly ruptures into the general peritoneal cavity is nearly always situated on the anterior surface far away from the parietal peritoneum and the sensory nerves The ulcer that causes the most suffering is either on the lesser curvature or at the pylorus unless it has already contracted adhesions to the parietal peritoneum elsewhere, so that it can drag upon it directly and the pain increases as *the movements of the stomach become more energetic* during digestion and ceases when they do Whether there are other accessory causes or not there can be no question that dragging upon the parietal peritoneum as the stomach moves during the process of digestion is the chief source of the pain in cases of dyspepsia and gastric ulcer

The reason for the intensity of the pain in so many cases of gastric ulcer is made clear in the same way Inflammation, starting from the lymphatics that drain the region of the ulcer spreads to the parietal peritoneum and makes it infinitely more sensitive Just as when the appendix is inflamed the parietal peritoneum which is continuous with its mesentery and in communication with its lymphatics becomes so sensitive that the faintest pressure upon the abdominal wall causes acute pain so it is with the stomach The lymphatics which drain the greater part of its wall converge towards the pylorus and the lesser curvature Whenever there is an inflamed area on the mucous surface or a sore that is irritated by contact

with the acid g

peritoneum in

inflammation i

with which th

enlarged glands are found in operations upon this region it is certainly more general than is usually imagined, but it is quite sufficient to render the attachments of the stomach more sensitive and to make the least pull upon them more painful than it was before As the cause of the pain in gastric ulcer is the movement of the stomach it naturally follows that it is felt most severely when the pyloric end is at work The cardiac end of the stomach is not in such close relation with the parietal peritoneum and in comparison is almost a passive receptacle The pyloric end is much more muscular and energetic In some instances the contraction of the pylorus itself is the immediate agent Jedlicka [1] for example describes spasmodic contraction of the pylorus as present in the majority of the cases of gastric ulcer associated with hyper acidity that were operated upon in Maydl s clinic In others it is the contraction of that ill defined but strong band of muscular fibres which surrounds the prepyloric region of the stomach and separates the antrum pylori from the rest Jedlicka in some of his cases describes this band as so much hypertrophied that when divided its cut surface was considerably greater than that of the pylorus In several instances I have found the same and in one case under my care section of these fibres (simple gastrotomy) effected a cure which seems as if it would be permanent The patient a man 39 years of age had suffered from pain and vomiting after food for three years and had had four attacks of hæmatemesis the two latest of which were serious When the stomach was opened neither ulcer nor scar was found All that was done was to divide this portion of the wall of the stomach

freely for the purpo

incision was sewn up

vomiting ceased Now

reports himself as still anæmic but except for that as well as he ever has been in his life In most of my cases however the contraction has not been confined to one or other of these parts but has involved the whole of this region It is very difficult to say what may be the normal size and thickness of the pyloric part of the stomach under varying conditions but I am convinced that in a large proportion of the cases in which I have operated for gastric ulcer it has been much thicker than it ought to have been especially in cases in which there was no marked degree of stenosis beyond

What is true of the pain in cases of gastric ulcer is also true of tenderness on deep pressure (The cutaneous hyperæsthesia so often present in this disorder is merely the expression of the irritability of the nerve centres kept up by stimuli reaching them from the visceral nerves) Tenderness on deep pressure is a measure of the sensitiveness of

---

[1] *Zur Operativen Behandlung des Chronischen Magengeschwürs.*

the parietal peritoneum. It means that this is in a state of active hyperæmia, or even of slight inflammation, kept up by irritation conveyed to it from the affected area on the wall of the stomach. Naturally, in the majority of instances the tenderness is greatest in the epigastrium, either in the middle line or slightly towards the right, for this corresponds approximately with the lesser curvature. When it is definitely localised elsewhere and persistent it usually indicates adhesion to the abdominal wall and if it is in the front the tenderness is often associated with contraction of the corresponding segment of the rectus.

This is not merely an academic consideration. It has a very important bearing upon the ultimate success of the operation for gastro-jejunostomy. The object of this operation, when it is performed for chronic gastric ulcer, is to drain the stomach and place it at rest. If this can be accomplished the vomiting and pain cease. If the pain continues it means that there is still dragging upon the sensory nerves under the parietal peritoneum around and that the operation has failed in one important particular. To accomplish this in all cases is no easy matter. If the ulcer is comparatively small, so that it can be excised and merely a thin linear cicatrix left without any puckered bands or adhesions, success is fairly certain. But in the majority of cases, by the time a surgeon is allowed to operate course after course of medical treatment has been tried and has failed and the wall of the stomach has become so far involved that excision of the ulcer means a fairly large gastrectomy. In such cases there is usually no option if gastro-jejunostomy is contemplated. The opening in the stomach must be made where it can be. But when there is a choice the opening should either be made quite at the cardiac end, so that the pyloric portion has no work to do; or if it is made near the pylorus there must be a very free division of the circular muscular fibres, as in the case of simple gastrotomy I have mentioned already. It does not matter so far as the stomach is concerned (the relation of the jejunal loop to the colon is a different question) whether the opening is made upon the anterior or the posterior surface; the weight of the bowel very soon drags it down into the most dependent position. But it is of the greatest importance for ultimate success either that the stomach should be prevented from doing any energetic work or, if this cannot be managed, that it should be prevented from dragging upon the parietal peritoneum by dividing either the fibres that enable it to do so or the peritoneal adhesions.

I have recently been engaged in tracing out the after-history of patients upon whom I have operated for various disorders in connexion with the stomach from two to ten years ago and I have been very much struck with the conspicuous absence of pain in some of the worst cases in which, owing to the presence of adhesions, I had been compelled to make the gastric opening quite at the cardiac end, a situation usually regarded as inadvisable. The reason, I think, is obvious. The pyloric portion ceases to contract or do any work if the opening is sufficiently free and the stomach no longer drags upon the sensory nerves in the parietal peritoneum.

Wimpole-street, W.

A CASE OF

RECURRENT OR SUCCESSIVE OVARIAN PAPILLOMA WITH SEQUENT VENTRAL HERNIA,

FOLLOWED BY CERVICAL EPITHELIOMA; TWO ABDOMINAL CŒLIOTOMIES; OPERATION FOR VENTRAL HERNIA; VAGINAL HYSTERECTOMY; RECOVERY.

BY E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON TO ANCOATS HOSPITAL, MANCHESTER.

IT is not often that any one surgeon is able to follow a case of this kind in its entirety, as patients so frequently change their attendants if one operation is followed by the necessity for another. It is therefore fortunate that in this instance it has been possible to record an unbroken series of events.

The patient was a widow, her husband having been dead 14 years before the first operation. She was a florid, stout woman and had had three children but no miscarriages. Menstruation had always been regular until August, 1898. She had always had pain for one or two days before each period, this passing off when the flow was established. In July, 1898, she consulted Mr. G. Knapton of this city for certain symptoms, when he discovered a tumour in the abdomen which appeared to be ovarian. In the middle of August of the same year whilst standing at the top of a flight of stairs she became giddy and fell to the bottom. Up to this time she had not herself noticed much increase in the size of the abdomen but now it began to increase rapidly and Mr. Knapton found that the defined swelling noted before had disappeared, whilst in its place the abdomen contained a much larger amount of free fluid. Various other changes were also apparent. Whereas previously the menses had recurred once every month, they now were seen every fortnight, whilst constant aching pain in the hips and sacral region was observed.

In November, 1898, the abdomen being greatly distended, she was tapped by Mr. Knapton who removed in this way three and a half gallons of clear amber viscid fluid. Before this there had been frequent desire to urinate, especially at night, associated with some difficulty. After the tapping this symptom disappeared. On Nov. 29th, 1898, I was requested to see her with Mr. Knapton in consequence of the rapid recurrence of distension with fluid. The circumference at the level of the umbilicus was 45½ inches. The vertical measurement from the pubes to the umbilicus was eight inches and from the umbilicus to the xiphoid cartilage 18 inches. The abdomen was somewhat pendulous. Percussion showed free fluid which moved somewhat slowly on change of position. The pulse was 108 and the respirations were 24. The last period finished on Nov. 11th, having lasted four days.

On Nov. 30th, the patient being in the dorsal position, a median incision was made between the umbilicus and the pubes, passing through the left rectus muscle, the fibres of which were bluntly separated by the handle of the knife. On opening the peritoneum there was an immediate gush of viscid—almost mucilaginous—amber fluid; loops of small intestine and thickened, lumpy omentum protruded. After a large quantity—several quarts—of fluid had escaped, the hand was introduced and passed into the pelvis. The fundus uteri was recognised and partially covering this and extending to the left side was a soft, pulpy mass which when brought into the wound resembled the interior of inflamed small intestine. It was red and velvety, of about the size of a small child's head, and was attached to the left broad ligament by a narrow pedicle. By the side of it lay a normal Fallopian tube with open fimbriæ. The pedicle was tied and divided, the peritoneum being sewn over the stump. No other growth was found and the left ovary and tube were healthy. On removal the under surface of the pulpy mass was smooth and looked like the wall of a cyst. It appeared to us as if a cyst had previously existed, had been burst by the fall, and become turned inside out. As large quantities of thick pulpy fluid still poured out two glass drainage-tubes were passed into Douglas's pouch and the abdomen was irrigated. The abdominal wound was closed down to, and around, these. As the patient recovered from the anæsthetic she began to retch and fresh quantities of the same pulpy fluid poured out, soaking the dressings, the patient, and the table. At 10 P.M. reaction had been good but a large amount of fluid had flowed through the tubes, requiring frequent changes of dressings and causing great difficulty in keeping the patient and the bed dry. This continued for 24 hours, after which the amount of fluid lost very rapidly decreased. One tube was removed on Dec. 1st, the next on the 2nd, and a small gauze drain left after the second tube was taken away on the 4th. The mucoid, viscid character of the discharge altered to reddish serum on the 2nd, three days after the operation. A catheter was not required, urine being passed normally on the 1st. Flatus was passed on the 2nd and the bowels acted well after a turpentine enema on the 3rd. The temperature was never above the normal. On the 27th she left the surgical home apparently perfectly well.

In August, 1899, the patient again noticed some increase in the size of her abdomen which became somewhat rapidly larger. In September she felt pain in the right inguinal and iliac regions and this became more intense in October, necessitating her confinement to bed. For a fortnight before observation this pain had been severe, preventing sleep, and for the last week had been accompanied by numbness in the right thigh. I saw her with Mr. Knapton, who had been in attendance, on Oct. 31st, 1899. The abdomen was greatly enlarged, the circumference at the umbilicus being 53 inches. There was free fluid in the abdomen. A large bilobed mass, dull on percussion, was felt in the hypogastrium extending from the pubes to some two or three inches above the umbilicus on either side. Pressure over this elicited some tenderness, most marked on the left side. There had been since the last operation some vaginal discharge which lately had smelt slightly. There was no pain on micturition or defecation but there had been some difficulty in the performance of the former act. She believed that she had lost weight. She could not lie on either side and was somewhat breathless. The heart and lung sounds were normal. There was no enlargement of the liver. Bimanual examination of the vagina showed that the uterus was normal in size and perfectly mobile, its movements not being communicated to the mass above. The os was split on both sides to the vaginal vaults but the surfaces were smooth and not friable. The examination [illegible] the [illegible] of [illegible] ned nearly in the line of the previous scar. On opening the peritoneum there was a gush of large quantities of similar yellow glutinous fluid as before. A mass similar to that previously removed was found springing from the edge of the right broad ligament. Its pedicle occupied the site of the right Fallopian tube which was not found. By its side, and external to it, was a firm body of the size and shape of an ovary, in which was imbedded a small cyst. Behind the uterus and adherent to it was another semi-gelatinous mass of the size of a small walnut. The peritoneum was injected and so was one coil of small intestine, the peritoneal coat of which presented a finely villous appearance. Both masses were removed along with the ovary; the abdomen was freely irrigated with saline solution until the latter returned clear and the abdominal wound was then entirely closed without drainage. Recovery was uneventful.

In January, 1902, the patient returned for the third time. There was a small ventral hernia at the site of the last operation but this did not give her much trouble. The symptoms of which she chiefly complained were a foul vaginal discharge, mixed with blood and associated with loss of flesh. On examination per vaginam the anterior lip of the os presented a crateriform ulcer with friable walls. On Jan. 26th the sac of the ventral hernia was dissected out. The opening through which bowel had escaped was double, each aperture being of the size of a shilling, and the two were separated by a narrow band of fascia. Both sacs had burrowed to some distance into the subcutaneous fat. After being freed they were twisted, after Ball's method, and ligatured, the excess being cut off and the stump reduced into the abdomen. One side of the fascia was then brought over that on the opposite side and united by mattress sutures. As [illegible] returned to [illegible] 2nd. [illegible] l and there had been no sickness. Vaginal hysterectomy was now done and the uterus was removed. As there was some troublesome hæmorrhage three or four clamps were left on the broad ligaments and the pelvic peritoneum was not united. The vagina was filled with gauze. This operation was followed by some vomiting with abdominal pain. Later there was much flatulence, with borborygmi. The catheter was used until after removal of the clamps which took place 48 hours later. After this urine was passed naturally. All sutures came away by the tenth day. Healing was complete [illegible] March 20th [illegible] he reported [illegible] operation [illegible] y growths. [illegible] ctive tissue centres, covered by well-defined columnar epithelium. There was a clear boundary line between the two which was perfectly continuous. The growths were evidently simple papillomata. Sections through the edge of the uterine ulcer showed cell nests.

Opinions differ somewhat with regard to these [illegible] Thus Giles and Sutton[1] say that there is reason t[illegible] that they arise in the paroophoron, that they always burrow between the layers of the mesosalpinx. They speak of them as always cysts in the beginning which may burst by overgrowth, the dendritic masses within then protruding and infecting the peritoneum; whilst Williams, in 1892, collected 26 instances of what he designates "surface papillomata." These growths, he says, are generally bilateral and invade the pelvic peritoneum, producing, as a result, hydro-peritoneum in most of the cases; and Senn[2] declares that papillary tumours on the surface of the ovary have been observed by Gusserow, Klebs, Birch Hirschfeld, and Winckel. Similarly the question of their innocency or malignancy appears hardly to have been decisively settled. Semb[3] declares that they are most benign neoplasms, do not cause cachexia, never give metastasis, are not destructive, and do not return. Pozzi[4] says they are ordinarily benign but may sometimes become malignant in the extreme. Alban Doran[5] says that the implantation of papillomatous growth on the peritoneum may prove clinically malignant within a few months or it may completely wither after removal of the tumour. Tauffar[6] insists that some papillomatous growths of the ovaries are essentially innocent, whilst others are distinctly malignant. He[7] makes ingenious comparison between them and the condylomata seen about the vulva in cases of gonorrhœa. In this case they were certainly bilateral but did not both appear at the same time. At the date of the first operation the right ovary, tube, and broad ligament were examined and found to be absolutely free from growth and although they were attacked later there was an interval of 13 months between the dates at which the patient's attention was drawn to the results of their respective invasions. It will have been noted that at the second operation a secondary mass was removed from the posterior uterine wall. When the uterus itself was taken away a little more than two years after no trace of the occurrence of such growth at any time could be found, the peritoneum, so far as could be seen, was healthy, and no fresh accumulation of fluid had taken place.

The patient has been, and remains, perfectly well (February, 1905).

Manchester.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ACUTE INTUSSUSCEPTION OF THE SIGMOID COLON DUE TO A SUBSEROUS POLYPOID LIPOMA; LAPAROTOMY; EXCISION OF POLYPUS; RECOVERY.

BY JOHN HOWSON RAY, M.B. VICT., F.R.C.S. ENG.

THE patient was a woman, aged 30 years, who was admitted to the Salford Royal Hospital on Dec. 1st, 1904, suffering from acute intussusception of the colon with complete intestinal obstruction and the protrusion of a subserous polypoid lipoma at the anus. She was seen by Dr. J. Stavely Dick two days previously and gave a history of abdominal pain in the left lumbar and iliac regions for the past six months; this pain was noticed chiefly at, and after, defecation. On Nov. 29th, 1904, she had very severe pain after defecation and was somewhat collapsed. Complete intestinal obstruction occurred on this day and vomiting was frequent and excessive. An enema given on Dec. 1st was followed by a violent expulsive effort during which a polypus as large as a medium sized orange protruded through the anus. This was taken to be the apex of the intussusception, an opinion verified by the subsequent laparotomy.

On admission to the hospital an operation was performed forthwith and an incision about four inches long slightly *to the left of the* middle line opened the peritoneal cavity and allowed the whole length of the intussusception to be made out. This was about 12 inches long; the neck was over the left sacro-iliac synchondrosis and the pelvic cavity [illegible] blood-stained fluid. By the aid of an assist[illegible] sception was raised to the [illegible] n this point reduction was fairly easy. The last part to unfold was at the junction of the middle and outer thirds of the omega loop, and this was brought out of the laparotomy wound and found to contain a tumour that completely blocked the lumen of this part of the colon. The colon having been incised the tumour was exposed and found to be the same mass that had protruded through the anus. The tumour was removed and it was necessary to cut through the wall of the bowel completely to effect removal, thus opening into the mesocolic angle. The wounds in the bowel were sutured with celloidin thread and the abdominal wall was closed in four layers, leaving a small drainage-tube at the lower angle of the wound so as to reach the bottom of the pelvic cavity. The after-treatment was simple and the subsequent progress of the case was uneventful. The tumour proved to be a circumscribed subserous lipoma, apparently growing from the mesocolic angle and producing an inverted diverticulum into the colon. The tumour measured two and three-quarter inches by two and a quarter inches by one inch in the three chief diameters and was ovoid in shape, weighing about two ounces five and a half drachms. The mucous membrane over the tumour was intensely congested and showed marked evidence of circulatory obstruction.

---

[illegible] 148

The patient was shown at the meeting of the Manchester Medical Society on Feb. 1st, when attention was drawn to the statistics of intussusception with special reference to cases of intestinal polypi and diverticula.

Manchester.

FRACTURE OF THE ANTERIOR FOSSA OF THE SKULL INVOLVING THE OPTIC AND SIXTH NERVES.

BY LAURENCE C. PANTING, M.D., B.CH. OXON.,
HONORARY MEDICAL OFFICER TO THE ROYAL CORNWALL INFIRMARY, TRURO.

THE following case seems to be worth recording on account of the somewhat unusual features which it presents, more especially as a similar case has been recently published in THE LANCET.[1]

A boy, aged eight years, was admitted into the Royal Cornwall Infirmary under my care with a history of having been run over by a cart, laden with stones, four hours previously. There had been no bleeding from the ears but there had been bleeding from the nose which had ceased before the arrival of the patient at the hospital. A lacerated wound in the scalp reached from a little below the parietal eminence to the coronal suture with a fracture of the skull extending its whole length, a second fracture almost vertically downwards meeting it about the middle. The angular piece of bone lying posterior to the vertical fracture was depressed. There was no subconjunctival hæmorrhage but there were ecchymosis in the right lower eyelid and surgical emphysema of the cheek due (?) to fracture in the antrum of Highmore. There were also bruising of the chest with surgical emphysema and acute tenderness over the sixth and seventh ribs. Although it could not be definitely made out there was almost certainly a fracture of the rib, as the absence of breath sounds and of voice sounds and the hyper-resonance of the percussion note showed that air was present in the pleural cavity also. The pupils reacted to light and were equal and moderately dilated. The boy was said to have been absolutely unconscious for about a quarter of an hour after the accident; he had regained partial consciousness when admitted into the hospital though he could not answer questions. The respirations were 48 and were shallow but regular; the pulse was 160 and regular and the temperature was 100° F. The urine contained a considerable quantity of sugar, due obviously to the cerebral lesion, but otherwise it was normal.

About two hours after admission an operation was performed for the elevation of the depressed fragment of the skull. The wound was somewhat enlarged and a small hole was trephined in the normal portion of the skull in the usual way and the depressed portion was elevated. The dura mater was found to be pulsating normally and was quite uninjured. The wound was then packed with gauze and the patient returned to bed. On the following day the boy was much better, the respirations had fallen to 34, the pulse to 120, and the temperature to normal; the urine was free from sugar and entirely normal. It was now noticed for the first time that though the position of the eyes at rest was normal, yet the right eye could not be moved outwards beyond the vertical meridian and the direct reflex to light was absent or present only to a very slight extent; the consensual reflex, however, remained normal. Vision with the right eye was very much impaired over the whole field of vision and the patient could only count fingers with difficulty. The fundus showed considerable changes, the papilla being swollen and blurred, the arteries diminished in size, and the veins swollen, while there were numerous bright hæmorrhages in the macular region. The boy made an uninterrupted recovery, the wound being healed in ten days and the lung regaining its activity in a little over a fortnight. The hæmorrhages in the fundus became darker and decreased until only a few of those close to the macula were visible, while the papilla became well defined and white and was clearly in a state of atrophy. This was the condition when the boy left the hospital at the end of three weeks entirely recovered excepting as regards the eye.

In this case it seems clear that the fracture reached forwards into the orbit and that the optic and sixth nerves were directly injured by it—in fact, an x ray photograph taken about a fortnight after the accident demonstrated the fracture reaching to the outer edge of the orbit. Since the continuity of both nerves was affected it seems probable that a like cause affected both and if this be so it can only have been direct injury by a portion of bone and not due to hæmorrhage into the sheath, since of course the sixth nerve is not like the optic provided with a sheath. The whole permanent injury, then, to the eye may probably be assumed to be due to the lesion of the nerves and this is supported by the fact that the consensual reflex was unaffected. The loss of the direct reflex must then be due entirely to the injury to the optic nerve and it is interesting to note that the reflex suffered considerably more than the conduction of light.

Truro.

ROYAL BERKSHIRE HOSPITAL, READING.

A CASE OF PERITONITIS DUE TO THE PNEUMOCOCCUS.

(Under the care of Dr. FRANCIS H. HAWKINS.)

A YOUTH, aged 16 years, was admitted into the Royal Berkshire Hospital under the care of Dr. F. H. Hawkins on April 14th, 1904, complaining of abdominal pain, vomiting, and diarrhœa. On April 9th the lad was quite well; on the 10th at night he was suddenly seized with severe abdominal pain; on the following morning he commenced to vomit and this vomiting continued until the day of admission. The bowels were at first constipated but for two days previously to admission they were moved three and four times during the day.

On admission the patient was noted to be lying on his back with his legs slightly drawn up. He was well developed, with dark hair, flushed face, eyes staring, and mouth firmly closed. The alæ nasi moved rapidly in respiration which was entirely nasal. The tongue was coated but moist. The abdomen was distended and moved but slightly in respiration; when the patient was asked to open his mouth and to breathe, however, the upper part of the abdomen moved freely, but oral breathing caused much abdominal pain which was general. Palpation, even of the slightest, caused pain in all regions. There were no dulness and no localising symptoms of appendicitis and rectal examination gave no indication of it. The lower border of the liver dulness was level with the costal margin. The respirations were 40, the pulse was 112, and the temperature was 101° F. Examination of the heart and the lungs gave no evidence of disease.

For two hours after admission the patient continued to vomit frequently, this being of an *olive-green colour.* Dr. Hawkins then asked his surgical colleague, Mr. J. A. P. Price, to see the patient with a view of operating. This was determined upon and when the abdomen was opened purulent fluid and flakes of lymph exuded The appendix was not diseased

Necropsy —(For the notes of this Dr Hawkins is indebted to Mr J R Thomas who was then house physician) "Abdomen large quantity of purulent fluid, whole bowel much congested, veins of mesentery engorged Bowels covered with lymph Appendix *normal* Spleen slightly enlarged, congested, other abdominal organs passively congested Lungs congested Heart normal' Thinking that the case might be one of pneumococcic peritonitis some of the pus was sent to the Clinical Research Association from which the following report was received "Media were inoculated with this specimen and from subcultures bacilli coli communis and a diplococcus indistinguishable from the pneumococcus were obtained

Remarks by Dr HAWKINS —From the above report I feel justified *in recording this case as one of pneumococcic* peritonitis But few cases have been recorded in British literature Sir Dyce Duckworth and Dr Frederick Taylor have both recorded cases in the Transactions of the Clinical Society, while Dr J H Bryant in a paper read at the meeting of the British Medical Association in 1901 records three cases In foreign literature however, this subject has received much more attention From a study of cases it appears that pneumococcic peritonitis occurs more in children than in adults more in girls than in boys and amongst adults more in men than in women When met with as acute primary peritonitis especially in cases sent into hospital with well [illegible] cult to distinguish [illegible] is so frequently [illegible] member that in pneumococcic peritonitis the onset is very sudden especially so in children, they are usually apparently quite well one day and the next acute abdominal pain arises followed by vomiting in nearly all cases and by diarrhœa in most Herpes may be present and the temperature in some instances *assumes the pneumonic character* In the adult, while the onset is equally acute, the pain may be violent colicky without vomiting or diarrhœa The attack may pass from the acute into a chronic stage with relatively few peritoneal symptoms This form of peritonitis may be local or general The prognosis of these cases is so far as the published cases in English literature are concerned unfavourable Thus out of six cases recorded only two recovered—one, a female aged 27 years, and the other, a girl, eight years of age Dr von Bonn, however, expresses *the opinion that the prognosis is good*

EGYPTIAN GOVERNMENT HOSPITAL, ALEXANDRIA

A CASE OF CONTUSION OF THE ABDOMEN, RUPTURE OF THE LARGE INTESTINE OPERATION, RECOVERY

(Under the care of Mr A WEBB JONES)

THE *patient a little Egyptian girl, aged 11 years*, was admitted to hospital about 4 30 P M on Dec 9th having [illegible] the seat of a large swing near [illegible] admission she complained of [illegible] mediately above the pubes and [illegible] en of urine obtained showed nothing abnormal The pulse was rapid but of good volume and strength She was treated with hot fomentations and rest in bed When first seen by Mr Webb Jones at 10 30 A M on the next day he found the child very restless and vomiting copiously a watery and bilious material The expression was anxious On examination the skin showed a transverse linear bruise of the right thigh immediately below the anterior superior iliac spine The upper half of the abdomen moved with respiration but below the umbilicus there was little or no movement Over the motionless area the abdominal wall was very tender and rigid, whilst the note was slightly impaired. The pulse was 140 but of fair volume and strength On re examination *at 2 30 P M the condition of* the abdomen was unchanged but the facial expression had greatly altered for the worse A diagnosis of ruptured intestine was made and the patient was at once sent to the operating theatre

On opening the abdomen (slightly to the right of the median line) a quantity of thin yellow, slightly feculent smelling fluid escaped and with it some flakes of lymph On withdrawing the first loop of intestine which presented a perforation was discovered of about the size of the tip of the little finger The bowel for a distance of about eight inches in either direction was intensely congested and covered in places with patches of adherent lymph Beyond these limits, however the gut presented a normal appearance Makins s clamps were applied above and below the perforation and the rent *was closed by a simple catgut suture invaginated* by a continuous Lembert s suture of silk In the course of the manipulations a small quantity of semi solid fæcal material was extruded from the rent The portion of gut (sigmoid flexure) affected was then gently sponged with hot sterile water and carefully examined At the same time, with the edges of the wound held widely apart so as to give free exit to the fluid the nozzle of an irrigator was introduced into the pouch of Douglas In this way, the mesentery of the sigmoid flexure forming *a sort of natural barrier the soiled section of the peritoneum* was thoroughly cleansed without attacking the general peritoneal cavity as a whole No attempt was made to remove any residual water and the wound was closed in layers, leaving a small gauze drain and rubber tube at the lower extremity Feeding was commenced in 24 hours with spoonfuls of lime water and milk in gradually increasing quantities The tube was removed on the second day and replaced by a very fine gauze wick The bowels were opened naturally on the fourth day and from that time recovery was *uninterrupted, the upper portion of the wound healing by* first intention

Remarks by Mr WEBB JONES —The diagnosis presented but little difficulty The general symptoms—pulse, vomiting, and facial aspect—or more especially their steady increase in severity in spite of rest and warmth made it certain that some serious internal injury was present At the same time the local condition of pain, tenderness, and rigidity in the lower half of the abdomen with an absence of urinary changes pointed to a rupture of *the intestine as the most probable lesion With regard to* treatment it would seem that where the intensity of the inflammation is limited a limited irrigation (as in the [illegible] than an irrigation of the [illegible] has published a case in [illegible] rent the patient died on the twelfth day from a second perforation The latter rupture had apparently resulted from the giving way of a second spot the vitality of which had been irrevocably damaged by the original accident His case emphasises the *importance of carefully* scrutinising the coil of bowel involved and if necessary of invaginating any suspicious spots with a Lembert suture A point of interest in the present case is the time (unavoidable) that elapsed before operative measures were employed This must have been at least 22 hours

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Subsequent Course and Later History of Cases operated on for Appendicitis

A MEETING of this society was held on Feb 28th, SIR RICHARD DOUGLAS POWELL Bart the President, being in the chair

SIR FREDERICK TREVES opened a discussion on the Subsequent Course and Later History of Cases operated on for Appendicitis He divided the matter for discussion under two heads—the first including the various degrees of imperfect relief or of imperfect recovery after operation and the second the complications which arose in connexion with the operation but which were not directly due to the primary disease For the materials on which his paper was based he was indebted partly to his own case books and partly to a large number of statistics which had been obtained for him by Mr Hugh Lett Mr Lett had written something like 800 letters to patients who had been operated on at the London Hospital for appendicitis with a view to obtaining information as to their subsequent history and had constructed statistical tables of 1000 cases of operation for

---

[1] Annals of Surgery, 1903

appendicitis at the London Hospital between July 1st, 1900, and August 15th, 1904. Imperfect results following removal of the appendix during the quiescent period were first considered and belonging to this class he had found 45 instances in his own books and 11 in the records of the hospital. The recurrence of attacks similar to those which had occurred before operation was due in some instances to the fact that there had been failure to remove the diseased appendix and in others to the presence of an appendix stump, a condition which emphasised the necessity of removing the appendix flush with the cæcum. In a much larger class the persistent symptoms had been caused by the presence of chronic inflammation of the right ovary and an example of such a condition in a woman, 30 years of age, was cited. Sir Frederick Treves thought that in order to avoid this possibility the right ovary should be systematically examined in all cases and that for the purpose a free opening by cutting the abdominal muscles was preferable to the more conservative method of splitting their fibres. In a certain number of cases a pre-existent colitis recurred after operation for appendicitis and gave rise to the statement of the patient that no relief had been obtained. Such cases usually recovered after several months of treatment. There were other cases in which constant pain in the right iliac fossa followed the operation and some of these were probably neuralgic in character and others were distinctly neurotic. The term neurosis was often a cloak for ignorance but it appeared to be appropriate to a patient who had resisted all ordinary methods of treatment and had eventually found relief in some form of "nature cure." Gall-stones, colic, moveable kidney, and renal calculi had been responsible for the return of symptoms simulating previous attacks of appendicitis in other instances. Finally there occurred tender painful lumps in the right iliac fossa, which in one case had been inflammatory, in three cases had been due to impacted fæces, and in another were the result of the presence of tuberculous glands. In 100 imperfect results following the evacuation of perityphlitic abscesses 40 were due to persisting sinuses, 24 to recurring abscesses, 16 to recurrent attacks of appendicitis, 12 to fæcal fistulæ, and eight to inflammatory deposits in the right iliac fossa. The majority of persistent sinuses were caused by the presence of a diseased appendix or a concretion. The recurrent abscesses, in the absence of a similar exciting cause, could be looked upon as independent of the appendicitis and common to all forms of local suppuration. The inflammatory masses were often diagnosed as pelvic sarcomata owing to their situation and extreme density but tended to resolve without special treatment. With regard to the presence of fæcal fistulæ four points should be remembered—viz.: (1) as long as the fistula persisted a second attack of appendicitis was extremely unlikely; (2) a fistula which was not due to actual cutting or tearing the bowel tended to heal spontaneously; (3) a fæcal fistula occurring some days after operation was more favourable than one which appeared at the time of operation; and (4) a diseased appendix or concretion was responsible for the persistent fistula in certain cases. An important question in the treatment of cases of perityphlitic abscess was whether, in the event of the appendix having not been removed at the time the abscess was evacuated, a second operation for appendicectomy should be performed in the subsequent quiescent period. With a most liberal estimate only 17 per cent. of cases showed any recurrence of symptoms after the abscess had been drained without removal of the appendix, and in 83 per cent. therefore such a second operation was unnecessary. Taking this fact and the well-known difficulty of the operation into consideration, the conclusion to be drawn was that a second operation should not be performed unless there was evidence of recurrent mischief. The complications associated with the operation for appendicitis were not fully considered and reference only was made to the fact that in 11 out of 12 cases of femoral thrombosis it was the left vein which had been involved, a circumstance which was not easily explained.

Sir WILLIAM BROADBENT considered that the discussion was one in which the physician could hardly take a part as it was unusual for him to be acquainted with the after-history of patients who had been handed over to surgical treatment. He was thankful that when imperfect results followed operative measures the patient almost invariably returned to the surgeon.

Mr. CHARTERS J. SYMONDS stated that in a series of 72 private cases he had met with one case of left femoral thrombosis, one fatal case of cardiac embolism, one case of non-fatal pulmonary infarction, and one pelvic abscess. 71 of these cases were perfectly relieved, although one was suffering from pain of renal origin. Out of 50 hospital cases there were no instances of venous thrombosis but two had recurrence of pain in the right iliac region. In one of these the pain was relieved by suturing the kidney and in the other the kidney was probably also at fault. Three cases had come under observation for recurrence of symptoms after operation by other surgeons. The right kidney was the seat of disease in two patients and in the third the symptoms were probably neurotic. Out of 37 cases in which the operation had been performed during the acute stage the appendix had not been removed in 14, two of which had had recurrence of suppuration. Mr. Symonds agreed with Sir Frederick Treves that thrombosis of the femoral vein was most common on the left side and he considered that the infrequency of its occurrence in his own series might be partly explained by the fact that he encouraged movement of the legs and the early attainment of the sitting posture after operation. In the absence of evidence of septic absorption it was sufficient to lay open a perityphlitic abscess and to drain it but when symptoms of septicæmia were present it was desirable to remove the diseased appendix.

Sir LAUDER BRUNTON thought that the majority of cases operated on for appendicitis remained perfectly well but a few returned to the physician with symptoms of chronic colitis which had existed previously. The pain in some of these cases was possibly due to adhesions involving nerves as it was not infrequently referred not only to the iliac region but also to the thigh. He had seen the symptoms of hepatic colic and those of appendicitis associated and in another case he had suspected the coexistence of pancreatic calculi and perityphlitis.

Mr. A. PEARCE GOULD based his observations on 300 cases of operation for appendicitis in private and hospital practice. He agreed that it was often difficult and sometimes impossible to remove the appendix but was fully aware of the disastrous results which sometimes supervened when the removal was imperfect. In only 10 per cent. of cases in which an abscess had been drained without removal of the appendix had there been any recurrence of symptoms; the justification for a secondary appendicectomy, therefore, was not evident without some special indication. Many complications had been observed, including femoral and internal saphenous thrombosis, cerebral softening, acute intestinal obstruction, ovarian suppuration, gangrene of the cæcum, and two cases of parotid bubo. Out of 214 cases of removal of the appendix without suppuration there had been only three deaths, one due to cardiac failure, one to septicæmia, and one to septic peritonitis. Out of 92 cases of perityphlitic abscess and general peritonitis 25 had died. There was ground to hope that with improved diagnosis and a clear recognition of the fact that operation should not be postponed until suppuration had taken place the mortality in cases of appendicitis would be very considerably reduced.

The meeting, which was very largely attended, was adjourned until Tuesday, March 7th, at 5 P.M.

MEDICAL SOCIETY OF LONDON.

Analysis of 300 Consecutive Gynæcological Laparotomies.—Some Remarks on Cæsarean Section.

A MEETING of this society was held on Feb. 27th, Mr. JOHN LANGTON, the President, being in the chair.

Dr. A. H. N. LEWERS read a paper based on an analysis of 300 Consecutive Gynæcological Laparotomies. Dr. Lewers gave in statistical form a very brief description of about 60 cases belonging to this series and these served to illustrate the great variety of conditions which he had found and the many difficulties that he had met with in dealing with different pelvic diseases. In summarising his results he divided his cases into nine different groups in the following manner: 1. Ovariotomy. 100 cases with no mortality. In 29 cases the ovaries on both sides had been removed and in 18 cases he had met with twisted pedicles. 2. Abdominal hysterectomy for fibroids. 73 cases with four deaths. Two cases had died from intestinal obstruction, one from shock, and one from peritonitis. 3. Removal of inflamed uterine appendages. 47 cases, four of which died. In each of the fatal cases the condition found was that of pyosalpinx. 4. Abdominal section for ectopic gestation, 33 cases and one death 5 Abdominal hysterectomy for conditions other than fibroids 17 cases with six fatalities Among these were instances of complication with such serious conditions as chronic Bright s disease, chronic bronchitis pulmonary embolism &c 6 Exploratory laparotomy 14 cases, of which five died In this series there were seven instances of malignant disease two of which proved fatal one case of intestinal obstruction, and one case of appendicitis 7 Cæsarean section Eight cases with one death, the latter supervening in a patient who had been in labour for four days before the operation was undertaken In six of this series section was performed on account of contracted pelvis and in the other two on account of tumours obstructing the pelvic outlet 8 Myomectomy Three cases with no deaths 9 Hysteropexy Five successful cases In the whole series there were 21 deaths, giving a mortality of 7 per cent

Dr W J GOW read a paper dealing with Cæsarean Section He reminded his audience that until recent years this operation had been one of almost academic interest and nearly invariably fatal Although it was now performed with much more success it did not yet occupy the important position which it should do and which he anticipated it certainly would do in the future His experience was based on 26 cases in which he had had no maternal death and in which all the children had been born alive although three had died in the early days of infancy In 25 of the cases the operation had been undertaken on account of contracted pelvis and in one on account of a fibroid obstructing labour The most advantageous time for Cæsarean section was at full term, either just before or during the first stage of labour and especially before the membranes had ruptured His first case was that of a rachitic dwarf and he was called upon to operate after labour had been going on for 12 hours The uterus was in a state of tonic contraction and had almost to be split in two a leg having escaped into the vagina and presented at the vulva There was very little hæmorrhage and silk ligatures were used in suturing the uterine wall The indications for performing Cæsarean section were (1) pelvic contraction or tumour obstructing labour, and (2) a child at or near full term and in a vigorous condition The latter was necessary because for some unknown reason infants delivered by this method were subjected to very considerable shock In the majority of instances the operation was simple and required very few instruments only one nurse and one assistant The abdominal incision need never be more than four inches in length and it was well to remember the extreme thinness of the abdominal wall in many women at the end of pregnancy The presence of the placenta on the anterior wall of the uterus did not in Dr Gow s experience add to the difficulties It should be rapidly cleared away from its attachments and not incised The child should be extracted if possible, by the feet and after the cord was tied, placed in a warm bath until he was disposed to breathe Artificial means of inciting respiration were to be avoided The uterus should be closed and returned into the abdomen as rapidly as possible in order to secure good contraction In ordinary circumstances the escape of liquor amnii into the peritoneal cavity was attended with no bad consequences but in one case in which the fluid had become contaminated by an ante partum vaginal discharge it had infected the peritoneum and given rise to several localised abscesses These had been opened and drained with success Dr Gow had not found that in performing a second section which he had done in three cases there had been any serious inconvenience due to the presence of adhesions He did not intend to perform symphysiotomy in any circumstances and he considered that the removal of the body of the uterus after Cæsarean section was not only superfluous but a step in the wrong direction

---

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases

A MEETING of this society was held on Feb 24th, Dr FREDERICK TAYLOR the *President* being in the chair

Dr J H BRYANT showed a case of Anæmia Splenica with marked pigmentation and clubbing of the fingers A man aged 48 years temperate who had never been abroad had in July, 1876 a severe fall and was struck on the left side of his abdomen In 1900 he suffered acute abdominal pain and was told that he had an enlarged spleen In January 1904 a severe attack of abdominal pain was accompanied by hæmatemesis He had a yellowish brown complexion, his fingers were markedly clubbed, and the spleen was enlarged and extended two inches below the umbilicus, there were numerous patches of dark brown pigmentation in the skin over the dorsum of the feet and the front of the legs, the urine was normal, the red blood corpuscles numbered 4 350 000 per cubic millimetre, there was 70 per cent of hæmoglobin, the *colour index was 0 8 and the white blood corpuscles* numbered 4375 per cubic millimetre —The PRESIDENT remarked on the rarity and obscurity of the case and mentioned another which resembled it in some respects but which had in addition a much enlarged liver —Mr W J HARRIS asked whether Dr Bryant considered that cases of splenic anæmia without pigmentation and clubbed fingers should be placed in a different category to the one exhibited —Dr A G PHEAR asked whether there had been at any time more evidence of anæmia than at the present and expressed doubts as to the propriety of using the name splenic anæmia in the absence of such evidence —Mr W G SPENCER referred to the presence of a traumatic history in the case and suggested it might be a case of splenomegaly similar to those occurring abroad in which excision of the spleen had relieved the symptoms —Dr F PARKES WEBER thought the pigmentation on the legs was hæmorrhagic in origin and that this suggested some primary disease of small blood vessels Perhaps some partial obstruction to the splenic vein might account for the enlargement of the spleen —Dr BRYANT in replying admitted the difficulty in naming the condition but thought that the association of splenomegaly with pigmentation and clubbed fingers justified the use of the term anæmia splenica

Mr EDRED M CORNER showed a case of Dislocation of the Atlas from the Axis with Fracture of the Anterior Arch of the Atlas A man, aged 21 years fell off a horse upon his forehead He 'saw stars but was able to mount the horse and to ride home A fortnight later the patient s neck was found to be rigid and he carried his head a little flexed and turned to the right He had a difficulty in opening his mouth, also in articulation and in mastication but not in swallowing The left transverse process could be felt between the mastoid process and the angle of the jaw, as to the process on the right side the examining finger found in its place a depression, whilst at the back of the pharynx on the right side there was a prominence A skiagraph showed the dislocation of the atlas from the axis on the right side and also a fracture of the anterior arch of the atlas The condition of the odontoid process was doubtful

Dr PURVES STEWART showed a case of Narcolepsy and Hysterical Blindness A man, aged 22 years, previously healthy had an attack of influenza six weeks ago A fortnight ago he complained of pain in the left side of the chest but there were no abnormal physical signs and he had insomnia for four or five nights He was then given 15 grains of sulphonal and slept for 19 hours continuously Since then he had had attacks of sudden sleep occurring at meals during games &c lasting several hours at a time Four days before admission he developed convulsive phenomena (opisthotonos &c) just before waking Three days

himself practically blind

from darkness and the

e kept the eyes directed

optic discs pupils and

cranial nerves were normal There was no headache or vomiting The urine was normal —Dr ALEXANDER MORISON thought that some such term as hypnolepsy would be more appropriate than narcolepsy and cited two cases of the latter condition in which the sudden attacks of falling asleep had been associated with marked cyanosis and other grave symptoms —Dr STEWART in reply stated that Charcot had used the name narcolepsy for cases similar to the one which he had shown

Mr A H TUBBY showed a case three years after Muscle grafting for Paralysis of the Left Upper Extremity In June 1901 the boy then aged ten years had infantile spastic paralysis of the left upper extremity The forearm and the hand were in the position of excessive pronation with flexion at the elbow and the wrist The fingers were strongly flexed The pronator radii teres was detached then passed behind the radius, and re attached so as to act as a supinator The palmaris longus and other flexor tendons at the wrist were divided The patient had regained extension at the elbow, supination of the forearm, and flexion and extension of the fingers, especially when the humerus was fixed.—Dr. E. FARQUHAR BUZZARD maintained that there was no evidence that the grafting of the pronator radii teres had been of any service; the forearm could only be brought to a position midway between pronation and supination and that movement was performed by the biceps, which could be felt to contract. He thought that the tenotomy would account for any other improvement which might have resulted from the operation.—Mr. HARRIS believed that the massage with which the patient had been treated since the operation might be responsible for any amelioration in the condition of the arm.—Mr. TUBBY, in reply, said that it was impossible to judge of the improvement without having seen the patient three years ago.

Mr. WILLIAM TURNER showed a case of Primary Sore on the Eyelid of a child, aged three years. The patient had been quite well until early in January, when, without obvious cause, a pimple formed on the margin of the right lower eyelid towards the outer side and had since steadily enlarged. An enlargement of the glands below the jaw on the right side was first noticed on Feb. 11th and there had since been a steady increase in size. The child had seemed ill since Feb. 18th. She had been sleeping with her mother. The mother, aged 29 years, had had several living children, two born alive who died after a few weeks, and one miscarriage. She was under treatment in August, 1904, for secondary lesions, mucous patches in the throat with enlarged glands, and an eruption on the hand.—Mr. CAMPBELL WILLIAMS expressed his opinion that acquired syphilis in young children was generally productive of severe constitutional symptoms and that it was important to get the patient under the influence of mercury. He advised the use of mercurial ointment on a binder.

Dr. J. G. SLADE exhibited a case of Lymphatic Leukæmia with microscopic specimens of the blood showing an enormously increased number of white blood corpuscles. The patient, a house painter, aged 49 years, had been in hospital under the care of Dr. W. H. Allchin. He had always been a teetotaler, was without venereal history, and was a moderate smoker. He began to complain in the autumn of 1902 of weakness and pains all over, and lumps in the neck were first noticed by his wife. In May, 1903, a medical man found lumps in the neck, axillæ, and groins larger then than they were at the present time. He improved under treatment but before admission lost flesh, was short-winded, and his face became yellowish. He had had no bleeding or diarrhœa or œdema of the ankles. He was found to have enlarged glands, supraclavicular, axillary, and inguinal; they were soft, discrete, moveable, and not tender. The liver extended two inches below the costal margin, the spleen was enlarged, extending two inches below the umbilicus, and the notch could be felt. His urine had a trace of albumin. Examination of the blood on Feb. 21st gave the following results: red corpuscles, 2,430,000; hæmoglobin, 24 per cent.; and white corpuscles, 1,300,000. The proportions of the leucocytes were: small, 96 per cent.; large, 3 per cent., and polymorphic, 1 per cent.; of the polymorphic five corpuscles were finely granular to one coarsely granular. Blood platelets were scanty.—Dr. PHEAR pointed out that although the polymorphic cells formed only 1 per cent. of the total white corpuscles there were 13,000 to the cubic millimetre, which was two or three times as many as the normal. He asked whether the large white cells belonged to the class of large lymphocytes or whether they were large hyaline cells of the ordinary type.—Dr. WEBER drew attention to the remarkably low hæmoglobin value considering the number of red corpuscles.—The PRESIDENT thought it would be interesting to learn when the changes in the blood developed and mentioned a case in which enlargement of lymphatic glands had preceded the leukæmic by nine months.

Mr. W. H. BATTLE showed a case of Disease of both Knee-joints. A man, aged 37 years, in 1902 was attacked by pain in the calves, the ankles, and the feet and in spite of treatment with salicylates and iodides developed effusion in the wrists, the elbows, and the knee-joints. At the end of 1903 the effusion in the knees had become more marked and the right knee was aspirated. It was now less swollen but the effusion in the left knee had increased.—Mr. CAMPBELL WILLIAMS asked what amount of iodide had been given and mentioned a case of a child in which he had mistaken a syphilitic for a tuberculous arthritis.

Mr. DOUGLAS DREW showed a girl, aged seven years, with complete restoration of function after Arthrectomy of the Knee-joint. Arthrectomy was performed in September, 1904, for tuberculous synovitis which had started after a fall two years before. The whole of the synovial membrane was studded with small tubercles. The sutures were removed a week after the operation and five days later a daily movement of the joint was commenced. A month afterwards some adhesions which limited movement were broken down under an anæsthetic. All swelling subsided and the child had been running about for some months with full movement.—Mr. T. H. KELLOCK thought that the result was so good that it threw some doubt on the original diagnosis. He considered that the tibiæ in both legs were suspicious of congenital syphilis.

Mr. DOUGLAS DREW also showed a case of Excision of the Navicular for Tuberculous Disease.

Mr. J. HUTCHINSON, jun., showed a case of Ossifying Sarcoma of the Left Fibula of two years' duration. The patient, a man, aged 40 years, had observed the tumour during the last two years. It overlapped the tibia and extended from a hand's breadth below the knee to the lower third of the leg. The radiograph proved that it grew from the fibula alone and that there was a large amount of bone towards its centre. It interfered little with the muscles of the limb but had caused a certain amount of pain. Pulsation in both anterior and posterior tibial arteries did not seem to be altered at the ankle. The patient had sustained no injury to the part and no other cause could be assigned for the development of the tumour.—Mr. G. EASTES pointed out the help which had been obtained from the radiograph in showing the origin of the growth from the fibula.—Mr. KELLOCK thought that the proper treatment was amputation at, or above, the knee.—Mr. DOUGLAS DREW believed that even amputation held out very little chance of ultimate recovery.—Mr. W. G. SPENCER agreed in the unfavourable prognosis of these cases.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on Feb. 17th, Dr. H. C. EARL, the President, being in the chair.

Dr. PEACOCKE showed a Liver which was a well-marked example of atrophic or multilobular non-alcoholic cirrhosis. It was obtained from a married woman, aged 30 years, who had been a teetotaler all her life. There was no syphilitic history and no apparent cause for the condition could be discovered. The duration of her illness was five months, ascites being first discovered three months before death. She had never had any gastric symptoms.—The PRESIDENT said that the connexion between alcoholic excess and cirrhosis of the liver had been assumed and partly proved but he thought that too much importance was placed on the alcoholic excess. In quite half of the cases which he had seen there was certainly none. It was hard to say whether there was syphilis or not but at any rate it was impossible to get a history of it. He had seen cases of typical cirrhosis in very young people, for example, in a child aged seven years and in a child aged 11 years. It was obvious that there was some other factor besides alcoholic excess; there were persons who drank all the alcohol they could get without having cirrhosis.—Professor O'SULLIVAN said that his own experience coincided with that of the President. Post-mortem examinations were made on numbers of drunkards in Dublin and fatty infiltration of the liver was usually found while cirrhosis of the liver was the exception; he was inclined to think that it might be due to the particular kind of liquor consumed. In experimental cirrhosis the disposition of the animal appeared to exercise a certain amount of influence on the result—that is, some animals of the same species would develop cirrhosis and others would not, as if there was a tendency in some individuals to the formation of increased connective tissue.—Colonel MCNEECE, R.A.M.C., said that during the last 15 years he had made many post-mortem examinations but had never seen a case of cirrhosis of the liver. The cases which did occur at Netley were in men who had served 15 years in India. Formerly each man was supplied with a dram of rum in the morning (and many men besides bought more liquor) but that had been done away with for the last 12 years or so and now nothing was seen of the hobnail liver in the army; he thought that it may have been due to a sort of crude alcohol manufactured in India from beetroot. Investigations of cirrhosis occurring in strictly temperate persons had been made in Canada.

Dr. Peacocke exhibited specimens from a man, aged 48 years, who had died from infective endocarditis, the duration of his illness being about six months. Infarcts were present in the lungs, the spleen, and the kidneys. In the brain there were three distinct hæmorrhagic infarcts, one in the inferior frontal convolution, another in the region of the temporo-sphenoidal convolutions, and another in the occipital lobe, all on the right side. For two months before his death the patient had suffered from aphasia. Vegetations were present on the tricuspid, mitral, and aortic valves and on the endocardial surface of the left ventricle and auricle. No aortic murmur was audible during life. No micro-organisms were found in the blood.

Dr. R. Travers Smith exhibited a specimen showing Perforation and Aneurysm of an Aortic Valve.

Society for the Study of Disease in Children.—A meeting of this society was held on Feb. 17th, Dr. Edmund Hobhouse being in the chair.—Mr. N. Bishop Harman showed a case of Unilateral Paralysis of the Third and Fourth Cranial Nerves of Congenital Origin.—Dr. Porter Parkinson agreed that it might be due to an anterior poliomyelitis.—Mr. Sydney Stephenson pointed out that in some cases there was a marked history of heredity.—Dr. Hobhouse showed a child, aged five years, with Hemiplegic Spasticity and Incoördination on the Right Side. Weakness of the right arm was followed a year later by incoördinate movements of the leg. Six months before any nervous symptoms appeared the child had convulsions. There was neither optic neuritis nor mental impairment. The condition had remained [illegible] eight months. There was [illegible] e right side and it was almos [illegible] jerk.—Dr. F. Parkes Weber showed a girl, aged 12 years, with Chronic Joint Disease, Splenomegaly, and Enlarged Axillary Glands. There had been a definite general reaction to tuberculin and he regarded this as a valuable indication for treatment.—Dr. F. J. Poynton showed a boy, aged eight years, with Chronic Arthritis which had begun without apparent cause three years before. The affection was most marked in the hands and the feet. The course was characterised by relapses and fever with a good deal of local pain. The [illegible] —Dr. Edmund Cautley showed a boy, aged nine years, with early Osteomyelitis or Epiphysitis of the Upper End of the Femur. He was admitted to hospital on Dec. 16th, 1904, as a case of rheumatic fever. The symptoms were pyrexia, [illegible] y frequent pulse, and pain and [illegible] the left thigh. An exploratory [illegible] egative in result. On Jan. 27th a skiagram showed definite changes in the neck and the upper part of the shaft and in both trochanters. On Feb. 8th pus appeared under the scar of the exploratory incision and on reopening the wound a probe passed down to bare bone. Dr. Cautley regarded the case as one of mild osteomyelitis or starting as an epiphysitis of the great trochanter.—Mr. Douglas Drew advised further exploration.—Mr. Arthur Edmunds showed a boy, aged seven years, with Syphilitic Arthritis of the Right Knee, forming a painless swelling, of two years' duration, which had markedly decreased under antisyphilitic treatment.—Dr. G. A. Sutherland showed a boy, aged 12 y[illegible] Knees of one month's [illegible] its contained free flui[illegible] lisease. He stated that in his experience drugs had proved of little use and that the affection ran a prolonged course, ending in spontaneous recovery.—Mr. Douglas Drew showed a case of Excision of Both Hip-joints for Tuberculous Disease and one of Acquired Club-foot with marked hereditary tendency.—Dr. G. E. C. Pritchard showed a child, aged two years, with Spastic Diplegia and Optic Atrophy. The head was microcephalic. Labour was difficult and prolonged. Spastic rigidity was almost universal and almost constant choreiform movements were present in the hands and the arms. Frequent mild fits occurred. The first fit was said to have been on the third day of life. There were no signs of intelligence. He regarded the condition as one of microcephalic congenital idiocy due to arrested or perverted development of the nerve elements.—Dr. Hobhouse showed a specimen of Congenital Absence of the Gall Bladder and Bile Ducts from a female, aged eight months, jaundiced since birth. The urine contained no bile salts or pigment. The fæces were white. The liver weighed eight ounces and the child nine pounds at death. There was marked interlobular cirrhosis.—Dr. Hobhouse also read a paper on a case of Interstitial Nephritis, with Extensive Renal Retinitis in a girl, aged six years. The eye symptoms appeared two months before death and were very intense. The urine was rather copious, contained a few hyaline casts, and blood for a time. There was no evidence of congenital syphilis but the child had had scarlet fever at the age of three years. The kidneys were exhibited.

Glasgow Medico-Chirurgical Society.—At a meeting of this society held on Feb. 17th Dr. David Newman delivered a presidential address on the subject "Cystoscopy, with Special Reference to the Use of the Cystoscope in the Diagnosis of Renal Disease" and demonstrated a large number of cases by means of an opaque projector in order to illustrate that in surgical diseases of the kidney the symptoms simply pointed to the direction in which information might be obtained, nothing more. For example, pain and hæmaturia might originate as a consequence of the disease of any portion of the urinary tract and while in many instances the character of the bleeding and the situation of the pain correctly indicated the nature and the site of the lesion, in others they seriously misled unless resort was had to physical proofs to guide and to correct the conclusions deduced from subjective symptoms. Cystoscopy—including the appearances of the bladder, of the orifices of the ureters, and the nature of the fluid which escaped from them—cleared up the differential diagnosis of bladder and renal disease, and at the same time enabled the surgeon to answer the questions: (1) Are both kidneys functionally active? (2) Are one or both involved in disease? (3) If one alone, which is it? The facts revealed by the cystoscope combined with the information obtained from bacteriological research, chemical examinations, radioscopy, and segregation of the urine, added to the ordinary clinical inquiry, enabled the surgeon to advise operation or to refuse it, knowing that he had employed all the methods of diagnosis at hand. Dr. Newman pointed out the advantages of Schlagintweit's catheter-cystoscope for diagnostic purposes and of the Casper-Hirschmann instrument (by which two observers could view the bladder at one time) for demonstrating lesions in the bladder. By means of the opaque projector and a translucent screen he demonstrated a systematic examination of the normal bladder and afterwards showed three dozen most realistic views showing: 1. Lesions of the bladder such as active hyperæmia, chronic inflammatory changes, sacculation, tuberculous disease in various stages, and simple and malignant tumours. 2. Changes in the bladder and orifices of the ureters in descending ureteritis, ascending ureteritis, periureteritis, and chronic nephritis in various forms. Also the various changes in tuberculous nephritis, renal calculus, and tumour of the kidney. 3. Jets of urine, blood, and pus being ejected from the ureters. Blood and pus clots were also shown slowly passing down the ureter and dropping into the bladder. The following conclusions were drawn: 1. When one ureteral orifice is altered while the other is normal the renal lesion is on the side of the morbid ureter. 2. When the urinary jets are more frequent on one side than on the other: (a) greater functional activity is indicated by the jets being uniform in size and regular in rhythm; (b) undue irritation of the kidney is to be inferred when the jets, while more frequent than normal, are irregular in rhythm, unequal, and small in size; and (c) stricture, stone, or chronic ureteritis should be suspected when the shoots are distorted in form or irregular in amount. 3. When the urine does not escape in distinct jets: (a) dilatation of the ureter without paralysis of the sphincter is indicated when the urine dribbles into the bladder at intervals; and (b) destruction of the sphincter action is shown by the urine flowing into the bladder almost [illegible] elbow, supination of the forearm, and flexion and extension of the fingers, especially when the humerus was fixed.—Dr. E. **FARQUHAR BUZZARD** maintained that there was no evidence that the grafting of the pronator radii teres had been of any service; the forearm could only be brought to a position midway between pronation and supination and that movement was performed by the biceps, which could be felt to contract. He thought that the tenotomy would account for any other improvement which might have resulted from the operation.—Mr. **HARRIS** believed that the massage with which the patient had been treated since the operation might be responsible for any amelioration in the condition of the arm.—Mr. **TUBBY**, in reply, said that it was impossible to judge of the improvement without having seen the patient three years ago.

Mr. **WILLIAM TURNER** showed a case of Primary Sore on the Eyelid of a child, aged three years. The patient had been quite well until early in January, when, without obvious cause, a pimple formed on the margin of the right lower eyelid towards the outer side and had since steadily enlarged. An enlargement of the glands below the jaw on the right side was first noticed on Feb. 11th and there had since been a steady increase in size. The child had seemed ill since Feb. 18th. She had been sleeping with her mother. The mother, aged 29 years, had had several living children, two born alive who died after a few weeks, and one miscarriage. She was under treatment in August, 1904, for secondary lesions, mucous patches in the throat with enlarged glands, and an eruption on the hand.—Mr. **CAMPBELL WILLIAMS** expressed his opinion that acquired syphilis in young children was generally productive of severe constitutional symptoms and that it was important to get the patient under the influence of mercury. He advised the use of mercurial ointment on a binder.

Dr. J. G. **SLADE** exhibited a case of Lymphatic Leukæmia with microscopic specimens of the blood showing an enormously increased number of white blood corpuscles. The patient, a house painter, aged 49 years, had been in hospital under the care of Dr. W. H. Allchin. He had always been a teetotaler, was without venereal history, and was a moderate smoker. He began to complain in the autumn of 1902 of weakness and pains all over, and lumps in the neck were first noticed by his wife. In May, 1903, a medical man found lumps in the neck, axillæ, and groins larger then than they were at the present time. He improved under treatment but before admission lost flesh, was short-winded, and his face became yellowish. He had had no bleeding or diarrhœa or œdema of the ankles. He was found to have enlarged glands, supraclavicular, axillary, and inguinal; they were soft, discrete, moveable, and not tender. The liver extended two inches below the costal margin, the spleen was enlarged, extending two inches below the umbilicus, and the notch could be felt. His urine had a trace of albumin. Examination of the blood on Feb. 21st gave the following results: red corpuscles, 2,430,000; hæmoglobin, 24 per cent.; and white corpuscles, 1,300,000. The proportions of the leucocytes were: small, 96 per cent.; large, 3 per cent., and polymorphic, 1 per cent.; of the polymorphic five corpuscles were finely granular to one coarsely granular. Blood platelets were scanty.—Dr. **PHEAR** pointed out that although the polymorphic cells formed only 1 per cent. of the total white corpuscles there were 13,000 to the cubic millimetre, which was two or three times as many as the normal. He asked whether the large white cells belonged to the class of large lymphocytes or whether they were large hyaline cells of the ordinary type.—Dr. **WEBER** drew attention to the remarkably low hæmoglobin value considering the number of red corpuscles.—The **PRESIDENT** thought it would be interesting to learn when the changes in the blood developed and mentioned a case in which enlargement of lymphatic glands had preceded the leukæmic by nine months.

Mr. W. H. **BATTLE** showed a case of Disease of both Knee-joints. A man, aged 37 years, in 1902 was attacked by pain in the calves, the ankles, and the feet and in spite of treatment with salicylates and iodides developed effusion in the wrists, the elbows, and the knee-joints. At the end of 1903 the effusion in the knees had become more marked and the right knee was aspirated. It was now less swollen but the effusion in the left knee had increased.—Mr. **CAMPBELL WILLIAMS** asked what amount of iodide had been given and mentioned a case of a child in which he had mistaken a syphilitic for a tuberculous arthritis.

Mr. **DOUGLAS DREW** showed a girl, aged seven years, with complete restoration of function after Arthrectomy of the Knee-joint. Arthrectomy was performed in September, 1904, for tuberculous synovitis which had started after a fall two years before. The whole of the synovial membrane was studded with small tubercles. The sutures were removed a week after the operation and five days later a daily movement of the joint was commenced. A month afterwards some adhesions which limited movement were broken down under an anæsthetic. All swelling subsided and the child had been running about for some months with full movement.—Mr. T. H. **KELLOCK** thought that the result was so good that it threw some doubt on the original diagnosis. He considered that the tibiæ in both legs were suspicious of congenital syphilis.

Mr. **DOUGLAS DREW** also showed a case of Excision of the Navicular for Tuberculous Disease.

Mr. J. **HUTCHINSON**, jun., showed a case of Ossifying Sarcoma of the Left Fibula of two years' duration. The patient, a man, aged 40 years, had observed the tumour during the last two years. It overlapped the tibia and extended from a hand's breadth below the knee to the lower third of the leg. The radiograph proved that it grew from the fibula alone and that there was a large amount of bone towards its centre. It interfered little with the muscles of the limb but had caused a certain amount of pain. Pulsation in both anterior and posterior tibial arteries did not seem to be altered at the ankle. The patient had sustained no injury to the part and no other cause could be assigned for the development of the tumour.—Mr. G. **EASTES** pointed out the help which had been obtained from the radiograph in showing the origin of the growth from the fibula.—Mr. **KELLOCK** thought that the proper treatment was amputation at, or above, the knee.—Mr. **DOUGLAS DREW** believed that even amputation held out very little chance of ultimate recovery.—Mr. W. G. **SPENCER** agreed in the unfavourable prognosis of these cases.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on Feb. 17th, Dr. H. C. **EARL**, the President, being in the chair.

Dr. **PEACOCKE** showed a Liver which was a well-marked example of atrophic or multilobular non-alcoholic cirrhosis. It was obtained from a married woman, aged 30 years, who had been a teetotaler all her life. There was no syphilitic history and no apparent cause for the condition could be discovered. The duration of her illness was five months, ascites being first discovered three months before death. She had never had any gastric symptoms.—The **PRESIDENT** said that the connexion between alcoholic excess and cirrhosis of the liver had been assumed and partly proved but he thought that too much importance was placed on the alcoholic excess. In quite half of the cases which he had seen there was certainly none. It was hard to say whether there was syphilis or not but at any rate it was impossible to get a history of it. He had seen cases of typical cirrhosis in very young people, for example, in a child aged seven years and in a child aged 11 years. It was obvious that there was some other factor besides alcoholic excess; there were persons who drank all the alcohol they could get without having cirrhosis.—Professor **O'SULLIVAN** said that his own experience coincided with that of the President. Post-mortem examinations were made on numbers of drunkards in Dublin and fatty infiltration of the liver was usually found while cirrhosis of the liver was the exception; he was inclined to think that it might be due to the particular kind of liquor consumed. In experimental cirrhosis the disposition of the animal appeared to exercise a certain amount of influence on the result—that is, some animals of the same species would develop cirrhosis and others would not, as if there was a tendency in some individuals to the formation of increased connective tissue.—Colonel **MCNEECE**, R.A.M.C., said that during the last 15 years he had made many post-mortem examinations but had never seen a case of cirrhosis of the liver. The cases which did occur at Netley were in men who had served 15 years in India. Formerly each man was supplied with a dram of rum in the morning (and many men besides bought more liquor) but that had been done away with for the last 12 in which medicines can be used. This lack of order must seriously militate against the use of these volumes by students and it is not compensated for by the index with which each volume is supplied. The most consistent section in the first volume is that which deals with the organic carbon compounds but this is disfigured by numerous misprints of common medical and chemical terms, and yet this section shows clearly that the authors have kept themselves well informed concerning recent advances in "Western Materia Medica." The first volume concludes with a classification of medicines according to their effects on the human system, with nearly 180 pages of "Therapeutics," this term being employed for long lists of drugs after the names of different diseases. Apparently the intention has been to limit these lists to the substances mentioned in this volume but the authors have allowed some drugs of vegetable origin to creep in as well as some curious names, such as "Panchnimb-churan" (p. 458), which does not occur in the index of either volume.

The plan of the second volume is much more satisfactory. There are only three sections dealing respectively with organic drugs derived from the vegetable kingdom, arranged according to their natural orders, with their classification according to their physiological effects on the human system, and, lastly, with their therapeutics, as in the first volume. The general principle adopted in this volume is to give a description of the *habitat*, characters, and properties common to the members of the natural order before dealing with the individual plant; after giving the *habitat* and the parts used, the plant is identified under the vernacular terms employed in different countries or different districts, then the characters are described, the constituents and preparations are named, and the actions and the uses are given from the therapeutic side. Questions of physiological actions or modern researches are rarely mentioned or only in such brief terms as to convey but little information.

It is possible that these volumes may be consulted with advantage by "western" practitioners when engaged in the East and anxious to know something of the local remedies but the work must be used with great discretion The following passage will show how far the thought of the East is from that of the West. "As a stimulant it is given in low fevers, epilepsy, and as a deobstruent and depurative in parotitis, dropsy, and other glandular diseases. It is an ingredient of various approdisiac *(sic)* confections. As a poultice it is applied to paralysed limbs and rheumatic swellings." A few lines lower we are told that this same drug acts by setting up emesis, that it is a diuretic, an astringent, an anthelmintic, that it is burnt as an incense, and that it is regarded as an insectifuge and insecticide for fleas, and so on. It is right, we think, to withhold the name of such a marvellous drug but the above is all culled from p. 628.

A *Text-book of Quantitative Chemical Analysis.* By J. C. OLSEN, A.M., Ph.D., Professor of Analytical Chemistry in the Polytechnic Institute of Brooklyn; formerly Fellow of the Johns Hopkins University. New York: D. Van Nostrand Co. 1904. Pp. 513. Price $4.

COMPLAINT is often made, with some justification we are bound to own, that too many text-books on the elements of chemistry and on simple qualitative analysis are published which cannot lay claim to any novelty in regard to the treatment or discussion of the subject. However true that may be of qualitative analysis the same can hardly be said of books on quantitative analysis. They are, in fact, comparatively few in number. The classic work is, of course, that by Professor Fresenius, to which we may add Sir William Crookes's "Select Methods in Chemical Analysis." Methods of analysis, however, are constantly being improved and modified with the view of yielding more accurate results. In particular considerable advance has been made with electrolytic methods of analysis and a section of the work before us by a well-known American analytical chemist gives interesting details of the application of electrolysis to the analytical determination of metals. In America analytical chemistry is making decided progress and, as a rule, the American chemist is characterised by his devotion to those details which are essential to really accurate results.

Dr. Olsen's book is divided into nine sections, in which the determination of metals, acids, the analysis of alloys, of minerals, electrolytic methods, volumetric analysis, oxidation, reduction and precipitation methods, and technical applications all receive adequate treatment. The author's familiarity with manipulative details is evidenced in his excellent instruction to the student on the precautions to be observed in order to attain accurate results and to facilitate their completion. We observe that the text is throughout well in accordance with modern developments of the subject which reflects great credit on the author in view of the large amount of periodical literature appearing in civilised countries recording from time to time the latest methods of analysis adopted by chemists in all parts of the world. The literature of quantitative analysis is, in fact, scattered and the book which, like the one before us, aims at successfully presenting an intelligible synopsis of these advances is obviously helpful. Moreover, there can be little doubt that the value of quantitative chemical analysis as regards its application to the arts and industries is rapidly growing in appreciation. Since many of our industrial operations are at some stage or other based on chemistry it is obvious that a high standard can be obtained only by adopting a system of scientific control over the industrial processes concerned. Dr. Olsen has produced a very useful and up-to-date guide on the subject.

A *Text-book of Physiological Chemistry.* By OLOF HAMMARSTEN of Upsala. Translated by JOHN A. MANDEL, D.Sc., Professor of Physiological Chemistry in New York University. Fourth edition. New York: John Wiley and Sons. 1905. Pp. 703. Price 17s. net.

IN this edition, which is translated from the fifth German edition, some of the older or at present untenable statements have been eliminated and certain chemical methods—not important for the physician or the student—have been less fully treated in order to give space for an account of the recent great advances in this subject and not to cause a too great increase in the size of the book.

The introduction is one of the best chapters in the book and will well repay perusal, for it deals with the fundamental questions of animal oxidations. Even on such a fundamental question as oxidation processes in the body, the very complexity and diversity of the views are set forth, including those of Pflüger, as dependent upon the special constitution of the living protoplasmic substance, the "biogen" theory of Verworn and the "active proteids" of Loewy. The theory of *catalases* which are supposed to liberate molecular oxygen and the still more modern and questionable view of oxidases are also considered. Even in ordinary combustion—e g., that of wood or oil—the substances themselves do not combine with oxygen. It is only after the action of heat has decomposed these bodies to a certain degree that the oxidation of the products of such decomposition takes place and is accompanied by the phenomena of light. The animal body may also have a source of energy in the cleavage processes which are not dependent on the presence of free oxygen, as, for example, in living muscle. The chapter closes with a general description of the intracellular and extracellular enzymes and their actions.

In the chapter on the "Protein Substances" the recent advances in our knowledge of the hydrolytic cleavage products of peptic and tryptic digestion are fully set forth The older view, that in peptic digestion only proteoses and peptones and no simpler cleavage products were formed, is now known not to be true. So also the "antipeptone" of Kühne is now known to undergo further cleavage. A full account is given of the hydrolytic cleavage products, such as alanin, aspartic acid, glutamic acid, and so forth, and the hexon bases, arginin, lysin, histidin, and so on.

Chapters III. and IV. deal with the carbohydrates and the fats. Chapter V. treats of the animal cell, and here we have a particularly full account of nuclein bodies and that important group of derived substances called the purin bodies. Naturally from one who has contributed so largely to the study of blood as Hammarsten we have a specially thorough and critical account of this fluid. On p. 159 the translator has introduced a word unfamiliar to English ears, "The teleostei are the first ...... to show an independence of the osmotic pressure of the inner *milieus* and the surrounding medium." Attention is prominently called to the fact that chlorophyll and blood pigments are closely related and are constructed from the same mother substance as one of "the greatest biological importance." There is a good summary of the very varied views held regarding coagulation of the blood. Then follow chyle, lymph, transudates and exudates, and then the liver. Chapter IX. deals with digestion. Some text-books hardly recognise the importance of saliva as an active medium by which a constant stream conveying the dissolved bodies passes into the blood from the intestinal canal during digestion. The recent observations of Pawlow are fully set forth and so are the actions of entero-kinase and the remarkable ferment erepsin discovered by Cohnhein in the mucous membrane of the small intestine, a ferment which Vernon has recently shown to be present in almost all the organs of the body. It does not act on fibrin, though it acts on the products of proteid digestion—proteoses and peptone —and on casein. The antipepsin, which prevents self-digestion of the mucous membrane and which is present in intestinal worms, is also mentioned. In addition we now know there is a gastric lipase or fat-splitting ferment which can act only on fat in a state of fine emulsion, as in the yelk of an egg, cream, or milk. Thus the fats of these foods may undergo partial digestion by the gastric juice. From the intestinal mucous membrane an antitrypsin can be obtained. The whole question of ferment—i.e., enzyme action—is assuming a new phase. By feeding an animal with a special food ferments are produced which are not present when that food is withheld, or in Brocard's dictum, "*C'est l'aliment qui fait le ferment.*" The remaining chapters deal with the connective tissues, muscles (including their metabolism), nerves, organs of generation, milk, urine, and skin. The last two chapters are on respiration and metabolism. The last gives a broad all-round view of the subject, a kind of *résumé* of the chemical processes occurring in the organism under different conditions.

Altogether this is one of the most compact, comprehensive, suggestive, and readable of the works on physiological chemistry which is somewhat liable to prove a toilsome study if the work be too largely chemical and too little physiological. There are no figures in the text. There is an uncoloured plate of spectra at the end and there is also an excellent index.

The Study of Chemical Composition. By IDA FREUND, Staff Lecturer and Associate of Newnham College, Cambridge. Cambridge: University Press. 1904. Pp. 650. Price 18*s.*

THIS is an admirable essay on the subject of chemical composition approached from the point of view of historical development. It is well to pause now and again in order to review the situation so far as it has advanced. There is a tendency amongst many workers in the field of science to become so absorbed in modern developments or their own particular branch of research that the complete history or the harmonious whole is left out of consideration. To such Miss Freund's essay may be strongly commended. Others, though not engaged actively in chemistry but who care to interest themselves in the position of chemical science and as to how that position has been built up, will read the book with profit. The study of Miss Freund's presentation of historical developments on the subject cannot, of course, pretend to take the place of extensive reading of original memoirs but it will admirably serve the purpose of those who have not time to spend in the laborious work of referring to scattered literature on the points dealt with. In fact, one of the most valuable features of her essay is that it contains the pith and substance of those original contributions which have given progress to chemical science. In the introduction the author generalises on the scope and the methods of the natural sciences and the study of facts by observation and experiment (with historical instances). The steps from observation to the detection of uniformities, to the consequent discovery of laws and the application of discovered law to the explanation of further facts (the deduction method) are next discussed in clear terms and the qualifications of a good working hypothesis are considered in natural sequence. After this interesting, though somewhat short, introduction Miss Freund proceeds to discuss the theories of combustion and this subject, of course, is perhaps one of the most important in connexion with the history of chemical science. Indeed, combustion may be said to be the foundation of chemistry. The discovery of oxygen, of nitrogen, and of air was the outcome of the correct observations made in regard to the nature of combustion. The author thus develops her subject through 19 chapters, each and all of which afford interesting reading. To many readers the nineteenth and last chapter, on the ultimate constitution of matter and the genesis of the elements, will appeal strongly as an attractive review of recent developments. The story of the genesis of the elements so vividly told by Sir William Crookes, of the fruitful researches amongst the stellar world by Sir Norman Lockyer, of the relations between electricity and matter by Professor J. J. Thompson as well as Sir William Crookes, and of the discovery of radio-activity as an atomic property by Madame Curie affords attractive and pleasant reading as bearing upon our knowledge of the constitution of matter. Miss Freund concludes her essay appropriately enough by referring to an impression prevailing amongst the general public that the recognition of the divisibility of the atom has dealt a deathblow to that atomic theory which was founded by Dalton just 100 years ago. This misconception (if it exists) had its origin likely enough in that subtle phrase which Mr. Balfour employed in his presidential address before the British Association for the Advancement of Science at Cambridge when he said that matter is not merely explained but explained away by assuming that the atom is now no more than the relatively vast theatre of operations in which minute monads perform their orderly evolutions while the monads themselves are not regarded as units of matter but as units of electricity. "Nothing," writes Miss Freund, "has had to be given up, nothing to be modified, but there has been deepening of the foundation, extension of scope, correlation with other sciences." Miss Freund has provided excellent intellectual pabulum in this admirable essay which we are sure will be read with pleasure and profit by all those eager to get a clearer glimpse into the nature of things.

LIBRARY TABLE.

The Essentials of Chemical Physiology, for the Use of Students. By W. D. HALLIBURTON, M.D. Lond., F.R.S. Fifth edition. London: Longmans, Green, and Co. 1904. Pp. 224.

Price 6s —This book runs so rapidly into further editions (which is evidence of its popularity and success) as to leave little that is fresh to say from the point of view of the reviewer In the present edition some important changes have been made in the arrangement of the exercises To begin with there is a new first lesson introduced on the detection of the elements contained in substances of physiological interest This naturally connects the work of the student passing from the study of pure chemistry with that of chemical physiology The fats again are now made the subject of a separate lesson Some new exercises have been inserted and a few of the advanced lessons have been rewritten This is the case with those relating to milk pancreatic digestion, muscle, and Kjeldahl's method of estimating nitrogen This method, however, must be modified in the case of certain nitrogen containing substances—for example, nitrites or even uric acid, require the addition of a reducing substance such as sodium thiosulphate coupled with phenol to prevent loss of nitrogen The book fully maintains its educational character

X Rays their Employment in Cancer and other Diseases By RICHARD J COWEN, L R C S Irel , L R C P Irel , &c London Henry J Glaisher 1904 Crown 8vo Pp 129 Price 2s 6d net This small book contains nothing startlingly new or original While ostensibly written to assist general practitioners who may wish to use the therapeutic properties of the x rays in treating their patients, it is difficult to imagine a work of 129 small pages doing more than merely touching the fringe of the subject and being used as the sole guide by anyone seriously contemplating the pursuit of x ray work The first chapter on the Focus Tube is really a short treatise on the x rays and their effects, while the second on the Coil, is conspicuous by the very few references to the subject of its title On p 41 the x rays are described as longitudinal rays which is not in accordance with the views of our most eminent physicists In the description of the technique the method of recording the volts and amperes in the primary circuit of the coil is still adhered to However useful this may be to an individual using the same equipment it is of little use to those who may wish to copy the procedure unless their apparatus happens to be an exact counterpart—a very unlikely contingency A record of the length of the alternate spark gap when working with a tube of well known make and pattern is much preferable In the case of a book published towards the latter end of 1904 we naturally expect at least some reference to the use of a milliamperemeter in circuit with the tube We notice what is said regarding the treatment of nævi and port wine marks and the removal of superfluous hairs by means of the x rays The opinion of x ray workers of large experience is not entirely in favour of this method, the results not justifying the risks necessarily incurred There are errors in spelling and at least one of the blocks has been misnamed The book adds nothing new to our knowledge of x ray therapeutics although it may be useful to those who would like to acquire a smattering of the subject

Premature Burial and How it may be Prevented By WILLIAM TEBB F R G S , and Colonel EDWARD PERRY VOLLUM M D , late Medical Inspector, U S Army Second edition, by WALTER R HADWEN, M D St And London Swan Sonnenschein and Co Limited 1905 Pp 454 Price 6s —The joint authors of this work attempt to show that the danger of being buried alive is very real and suggest that the duty of taking effective precautions against it is one that naturally falls to the legislature In the preface to the second edition Dr Hadwen writes that "the careful study of the subject which the work has entailed and the perusal of the evidence collected from various parts of the world, which has accumulated considerably since the first edition was published in 1896, have convinced me of the real need in this country of drastic and far reaching reforms in connexion with our burial system" The most important conclusion is that no evidence of death is really satisfactory except that which is supplied by putrefaction, usually evidenced by the change of the colour of the abdomen, and that to insure this safeguard waiting mortuaries should be erected by every sanitary authority in the kingdom at the public expense Such mortuaries would however be quite unnecessary if direct medical testimony were required

JOURNALS AND MAGAZINES

The Phonographic Record of Clinical Teaching and Medical Science —The January number of this journal, which is now published quarterly instead of monthly, contains two excellent articles The one by Mr C W Cathcart, deals with the subject of Recent Methods of Diagnosing the Relative Conditions of the Two Kidneys in Surgery and is well worth study by those who wish to be *au courant* with the latest surgical methods of diagnosis The article by Sir William R Gowers is in his well known exhaustive style and deals with Syphilitic Disease of the Brain The number also contains the annual report of the honorary secretary of the Society of Medical Phonographers

Reports and Analytical Records

FROM

THE LANCET LABORATORY

SODIUM PERBORATE (WELLCOME BRAND)

(MESSRS BURROUGHS WELLCOME AND CO SNOW HILL BUILDINGS, LONDON E C)

SODIUM perborate is an interesting example of a compound which yields two well known antiseptic substances on dissolving in water It is a well defined salt which in water gives off nascent oxygen the solution containing practically borax and peroxide of hydrogen On adding permanganate of potassium to the solution a brisk disengagement of oxygen takes place Similarly, on adding chromic acid and ether a dense blue colouration is produced which dissolves readily in the ether The blue compound is perchromic acid Sodium perborate may be employed both as an internal and an external antiseptic The solution is non acid and free from irritating properties The salt may be employed as a dusting powder to suppurating surfaces the available oxygen being particularly helpful in such a case the gas being brought into close and continued contact with the seat of suppuration The salt is stable Sodium perborate is obviously both a disinfectant and a deodorant

RECORD OLD SCOTCH WHISKY

(MESSRS S FAWKES AND SONS 8 AND 9 KENDRICK STREET, STROUD)

The analysis of this whisky gave the following results extractives 0 01 per cent , mineral matter, *nil*, alcohol by weight 39 30 per cent by volume 46 59 per cent , equal to proof spirit 81 64 per cent The secondary products amounted to the following, given in grammes per 100 litres of absolute alcohol present acidity reckoned as acetic acid 26 00 , aldehyde 5 40 , furfural, 1 60 , ethers reckoned as ethyl acetate 40 00 , higher alcohols, 65 00 , and total secondary products 138 00 These results indicate that this is not an all malt spirit and that it contains not less and probably more than 50 per cent of neutral spirit, whether it be called patent, grain, or anything else The

he character of the

gards malt The

blend

CHOCOVUM

(DR BRY, PARIS AND 64 NEW OXFORD-STREET LONDON W C)

As its name implies this is a preparation of chocolate containing egg substance Some proof of the presence of egg in the chocolate is afforded in the fact that the fat extracted was found to contain phosphorus. The total amount of fat was 40·85 per cent., part of which is, of course, derived from the cocoa. The proteid amounted to 8·26 per cent. and the mineral matter to 1·80 per cent. Chocovum is clearly a preparation possessing peculiar nutritive qualities. It is further palatable and doubtless contains nuclein and lecithin which are admitted to be valuable in promoting nutrition.

CALOX.

(Messrs. McKesson and Robbins, New York; London Agents, S. Maw, Son and Sons, 7–12, Aldersgate-street, London, E.C.)

A novel and important feature of this dentifrice is that on application to the teeth or in contact with water it yields nascent oxygen. It is, therefore, not only antiseptic but deodorant—two desirable properties of a tooth wash. In addition it contains a well-known aromatic antiseptic which makes it agreeable to use. Calox is a dry powder containing a definite proportion of calcium dioxide, which in contact with acids gives an equivalent of hydrogen dioxide. Its oxidising and deodorising power was obvious in our experiments.

DIABETIC SPICE BUNS.

(Messrs. Callard and Co., 74, Regent street, London, W.)

The statement that these buns are free from starch and sugar is according to our analysis correct. Carbohydrates are in fact displaced by proteid and fat. The proteid behaves in the same way as that present in milk. The fat amounted to 27·30 per cent. and the proteid to much the same figure. The buns are palatable and though free from sugar have a slightly sweet taste.

GILMOUR'S OATMEAL STOUT (QUAKER BRAND).

(Messrs. Ellis and Co., Hill-street, Richmond, Surrey.)

It might be expected that the use of a proportion of Scotch oats in the brewing of malt liquor would add to its nourishing properties, since the oat contains considerably more proteid than does barley and moreover an abundance of phosphates. Our analysis of this stout proved such to be the case, for phosphates were present in distinct amount and the extractives contained 12 per cent. of proteid. The stout has an agreeably "smooth" and "soft" flavour and is free from an undesirable excess of carbonic acid gas. Further, it was in ripe and sound condition, being comparatively non-acid. The total extractives amounted to 5·20 per cent.; the mineral matter, 0·15 per cent.; while the alcohol by weight amounted to 5·87 per cent., by volume 7·32 per cent., and proof spirit 12·84 per cent. The stout is of good quality and well brewed, containing an excellent proportion of the soluble nourishing constituents of malt and oats.

SULTANA BREAD.

(Messrs. Pelling Stanley and Co., Limited, 28, Mathew-street, Liverpool.)

The specimen loaf submitted to us proved to be simply bread containing sultana raisins. Each two-pound loaf contains about half a pound of sultanas. The idea is of some dietetic interest, since raisins are nutritive, while they tend, like most fruits, to promote intestinal action and to correct proneness to constipation. We should imagine that the school-boy would view this preparation with some interest and indeed it forms, especially when buttered, a wholesome departure from the daily slice of bread.

BITTER BEER.

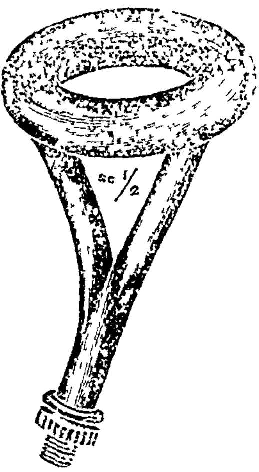
(Joseph Dunn, 21, Greenhead-street, Calton, Glasgow.)

According to our analysis this beverage contains not more than 2 per cent. of proof spirit, so that it is safe to describe it as non-intoxicating. The extractives amounted to 1·90 per cent. and the mineral to 0·14 per cent. The extractives consist chiefly of sugar, since this substance amounted to 1·25 per cent. The beer is evidently a brewed liquor and contains the extractive principles of hops. The beer is bright and effervescent and the flavour for this class of beverage is not unsatisfactory.

New Inventions.

A SPRING STEM PESSARY.

We have received from Messrs. Maw, Son, and Sons a new form of spring stem pessary. The general appearance of the appliance may be seen from the illustration. Both ring and stem are made of watch spring covered with indiarubber. We consider that this form shows many advantages over the rigid form of stem pessary and it should prove decidedly useful in cases of prolapse. The resiliency is a great advantage, but it would be an improvement if the screw portion which fixes into a tape bandage were made shorter so as not to project beyond the vulva to any extent.



A PORTABLE LAMP FOR USE IN LARYNGOLOGY.

The accompanying illustration shows a portable lamp that I have adapted for use in examination of the ear and upper respiratory passages. It consists of a cycle acetylene lamp with a flat flame burner. The reflector is blackened inside to prevent unequal lighting of the field by reflected rays. In front of the lamp I have had a lens placed with a diameter of two and a quarter inches at a distance of three inches from the flame. This lens is fitted into one end of a tube which screws at its other end into a plate attached to the front of the lamp window from which the glass has been removed. By means of the screw thread on the tube the distance between the lens and the flame can be adjusted so as to give a beam of light with rays as nearly parallel as possible. The lamp bracket is attached to the top of an aluminium camera stand by a detachable metal plate and the lamp can be turned to one or other side. In the illustration the telescopic legs of the stand are shown closed up; they can, however, be drawn out so as to give various heights up to 45 inches from the ground. The lamp and stand together weigh 2 pounds 4½ ounces and they are easily carried in a bag as they take up comparatively little space. The light is very bright, the field illuminated from a head-mirror is clear and free from shadows, and I have found the arrangement most satisfactory. If preferred, the lamp can be attached by a moveable arm to a vertical rod which clamps on to the edge of a table. It is sufficient to put a small amount of calcium carbide in the chamber at the base of the lamp *before going out* and then fill the water reservoir when the light is required. There is no unpleasant smell from the lamp if the flame is not blown out or the carbide chamber opened while in the house. After use it ought to be cleaned out regularly. It may be obtained from Messrs. Philip Harris and Co., Birmingham.

THE LANCET.

LONDON: SATURDAY, MARCH 4, 1905.

Overwork.

THE death of an unfortunate baker's journeyman, concerning whom it was testified by a medical witness at the inquest that having heard the non-medical evidence and the history of the case he was satisfied that the deceased had died from heart failure accelerated by overwork and long hours, is an event not unworthy of notice by the hardest worked of all professions In the case in question, on which we do not desire to lay any particular stress, it was shown that the man was accustomed to work in a bakehouse, probably not better than other bakehouses in respect of cubic space and air-supply, for 15 hours a day during the earlier part of the week and for 23 hours on Saturdays and that he had for some time been complaining of "shortness of breath," but he does not appear to have been subjected to any medical examination. On the day of his death, a Friday, he commenced work at 9 P.M. and would have gone on until the evening of Saturday. About 11 P.M. he ate some fried fish and returned to work but soon after doing so he fell forward and expired. There was no post-mortem examination and nothing to show what was the actual cause of death, which may, of course, have been of a kind with which the hours of work had nothing to do except perhaps by way of predisposition. Pathologically the verdict was entirely unsatisfactory but it was perhaps sufficient for the protection of society. It is at least certain that the deceased was not the victim of foul play and that his death could not be traced to any legal offence. The ready assumption by the medical witness that death had been due to, or accelerated by, overwork and the equally ready acceptance of this assumption by the coroner and the jury not unnaturally lead us to look a little more closely at the meaning of the word and to inquire whether what it denotes must indeed be recognised as a possible or perhaps a frequent cause of premature mortality. A general practitioner in full employment is probably the hardest worked of civilised men, both physically and intellectually, and his life is not a long one According to the elaborate tables published by Dr. J. F. W. TATHAM in 1897 the comparative mortality figure for medical men was 966, as against 821 for lawyers, 533 for the clergy, and 953 for occupied males in the aggregate; and previous inquiries made by Dr W. OGLE showed that, notwithstanding the generally high mortality of the profession, there were three numerically important headings, pulmonary tuberculosis, other diseases of the respiratory organs, and accident, under which this mortality was lower than that of the male population generally. On the other hand, the medical mortality from diseases of the liver, from diseases of the circulatory and urinary systems, and from suicide was greatly in excess of the average, whilst that from diabetes and from gout was more than three times as heavy as among the male population in the aggregate. Statistics of this kind are to some extent vitiated, of course, by the circumstance that they deal with the profession as a whole and furnish no means of discrimination between its successful and its unsuccessful members. The former, presumably, will furnish the examples of overwork and the suicides will be mainly recruited from the latter.

Ingenious attempts have been made by MASCHEK and other writers to classify work under the three headings of effort, velocity, and duration, and to arrive at formulæ which should show the proper relations of these three elements to each other. Such attempts have not been conspicuously successful but they at least serve to call attention to the distinctness of the elements in question and to the necessity of taking each of them into consideration when endeavouring to estimate the output of an individual. They remind us that the spurt of a tired man may be more injurious to him, may, in common parlance, "take more out of him" than sustained efforts more deliberately accomplished; and it must be remembered that the exceptional work of medical men is quite commonly of this character. A country practitioner who has come to the close of a busy day is suddenly called upon to make a hasty journey and on arriving at his destination to confront some emergency, surgical or obstetric, with which it will require all his energies to cope. It is a not uncommon experience in such cases that even when released he may not be able to obtain the repose which he greatly needs, either because of the pressure of new duties or because his mind cannot relinquish the memories of what has just been done. It is not everyone who can say, like the late Sir WILLIAM JENNER, "I don't think that anxiety about a patient ever kept me awake for five minutes in my life. I go to a bedside. I do my best. What more can I do? Why should I not sleep?" It is quite possible to find in these words an explanation of the fact that a life unusually filled with arduous work and with the most onerous responsibilities was nevertheless prolonged to the age of 83 years. Herein, it may be, should be sought the lesson which the contrast between longevity on the one hand and undue mortality on the other is best calculated to teach to those who will read the events aright. MASCHEK succeeded in establishing at least one formula which appears to show that the time occupied in strenuous effort should not greatly exceed one-third of the 24 hours, and the experience not only of Sir WILLIAM JENNER'S success but of the contrasts furnished to it by innumerable failures may be said to show with at least equal distinctness how much depends upon the complete relinquishment of effort, whether physical or intellectual, when the time for cessation from it has arrived.

We know too little about the physiology of sleep to dogmatise concerning the reasons which render it a necessity, but we know from experience that, save in the cases of very exceptional persons, the hours devoted to it cannot be curtailed without serious injury—injury which often falls upon the work and which never fails to fall upon the worker. The first Lord TRURO was one of the exceptional persons referred to and after sitting up over briefs and papers until three in the morning he would awake refreshed at six and would be ready for the labours of another day. This life he led for many years but when he was Lord Chancellor his successive private secretaries rapidly gave way under the stress of his requirements and he himself, although he reached the age of 73 years, was incapacitated from exertion for some time before his death and spent his two last years in great suffering. Sir ANDREW CLARK was fond of telling his patients that "nature never forgets and seldom forgives" and the lesson which the words convey is a true and wholesome one. If we disregard exceptional cases we shall find it generally true that it is more easy to exceed the powers of the system than to husband them, and true also that to husband them is the way of wisdom. Of the three elements of work mentioned above that of duration is usually most under our command and those who would retain health and attain longevity should see to it both that their efforts are not too prolonged and that they are followed by corresponding periods of rest. Lord PALMERSTON, during his last premiership, made it an absolute rule after returning late from the House that he should never be disturbed on any pretext until he had been eight hours in bed ; to the observance of this rule he was probably much indebted for the health and vigour which enabled him to spend most of the eightieth anniversary of his birth on horseback, inspecting fortifications in the neighbourhood of Portsmouth. If we turn to the element of velocity in work we shall find abundant reasons for the belief that its predominance implies an amount of strain greatly in excess of the actual accomplishment and calls for a corresponding equivalent of repose. The wise man, who realises that he must spend his life in living, will be all the more solicitous so to manage his expenditure that it may not be wasteful and he will be careful to guide his activities to this end. He will realise that his day's work, whatever its amount, will be rendered almost indefinitely more easy of accomplishment by method and arrangement and by steady refusal to break through these except for very cogent reasons. He will realise that exceptional duration and exceptional speed of work should be avoided whenever possible and that, when they cannot be avoided, they should be followed by correspondingly exceptional periods of repose. He will realise, lastly, what is perhaps the most important thing of all—namely, that men are not so much killed by work as by worry. He will render himself master of the course of his own thoughts and will dismiss from them for the time all anxieties as to which he has once arrived at a conclusion. Having decided to pursue a course of treatment he will wait until he next sees the patient before beginning to consider the character of its operation. He will not hunt his hares over again but will say with Sir WILLIAM JENNER, I have done my best, why should I not sleep soundly and so assist nature in preparing me for the cares and responsibilities of another day.

◆

Arsenic in Textile Fabrics and Wall Papers.

THE Bureau of Chemistry at Washington has in recent years carried out a large amount of useful analytical work in matters affecting the public health of the United States of America. In Bulletin 86, 1904—one of the numerous reports from this department which suggest that similar official work should be done in this country—Mr. J. K. HAYWOOD and Mr. H. J. WARNER give an account of an examination of various wall papers and fabrics which was undertaken in order to ascertain whether they contained arsenic. This is a subject which was not fully investigated by the recent Royal Commission on Arsenical Poisoning, the reference of which was limited to foods and drinks. Incidentally, however, the minutes of evidence of that Commission gave some useful information on the subject as regards this country. The Commission ascertained that although Scheele's green and other salts of arsenic are still used in certain articles of domestic use, such as candles and tapers, their employment to colour wall papers has been discontinued. Arsenic, however, may be present in a variety of the "aniline" pigments; in a few instances (magenta dyes) arsenic may have been employed in the manufacture of the colour but in most cases the arsenic has been derived from the use of unpurified oil of vitriol in the manufacture of the dye. The Commission's inquiries also brought out clearly the extreme susceptibility of some individuals to quantities of arsenic much smaller than those which are ordinarily given medicinally and the importance of the individual factor cannot be lost sight of when dealing with the present question. The harmful effect of arsenic when present in articles of apparel, such as coloured stockings, is probably restricted to the production of local affections of the skin of one or another kind. With carpets, rugs, and furs, which do not come into contact with the skin, the risk lies in opportunities of inhaling or swallowing arsenical dust and this may be considered of importance only when the material is highly arsenical—for example, furs such as those in which Mr. HAYWOOD and Mr. WARNER found 17 grains of arsenic in the square yard. With wall papers, however, the case is different. It has been clearly shown by GOSIO and others that when ordinary moulds—mucor mucedo, penicillium glaucum, and especially penicillium brevicaule—are added to organic substances containing arsenic, arseniuretted hydrogen and other highly poisonous volatile compounds are evolved. A very delicate test for arsenic is based on this property of moulds. The moulds in question have been shown to be frequently present on papered walls and there is evidence that in these circumstances they cause the evolution of volatile compounds of arsenic, if arsenic is present in the paper. Mr. HAYWOOD and Mr. WARNER quote certain recent cases of arsenical poisoning attributed to wall papers. It is noteworthy that several of the patients did not suffer conspicuously from catarrh, sore throat, or diarrhœa; their principal symptoms were obstinate neuralgia, dyspepsia, and general lassitude. Obviously the association of symptoms of this kind with arsenic might easily be overlooked and caution is therefore necessary in assuming that the small number of cases reported of late years signifies that arsenical poisoning by wall paper has almost become a thing of the past. The important indications which may be obtained by examining the urine of the patient in doubtful cases, or the hair, as suggested by the Royal Commission, should not be forgotten.

Certain countries, notably Germany and Sweden, prohibit the manufacture or importation of textile goods which contains more than a minute and prescribed proportion of arsenic. In America the matter is left to the different State legislatures and Massachusetts alone has a law on the subject. In this State, by an Act of 1900, textile fabrics in general must not contain more than one-tenth, and what are termed "dress goods" more than one-hundredth, of a grain of arsenic per square yard. These limiting quantities have been taken by Mr. HAYWOOD and Mr. WARNER as a basis of comparison when testing large numbers of different articles obtained from different sources in the United States. As a whole their results were satisfactory when judged by these standards. Many samples of furs, carpets, drapery, and "dress goods" contained no arsenic which was detectable by the delicate methods employed. The arsenic in some "dress goods," however, far exceeded the one-hundredth of a grain limit—e.g., a coloured print which yielded 0·24 grain of arsenic per square yard, and a number of black stockings, articles which seem specially liable to contain arsenic. As many as 537 wall papers of different colours and origins were tested. The results show that there is no commercial reason why arsenic should be present in plain, glazed, or coloured wall paper. The majority of samples were free from arsenic or contained merely a trace which could not be estimated quantitatively. One firm supplied a series of wall papers of many different colours in none of which was even a trace detected. Only a few wall papers transgressed the somewhat lenient Massachusetts limit of one-tenth of a grain per square yard. Two of these were of English manufacture. Several others, however, were very little below the one-tenth of a grain limit. The colours of the arsenical samples were various—reds, blacks, and greens were most often concerned. It is common in this country to see the legend "arsenic free" stamped at the back of a wall paper. But in view of the analyses of Mr. HAYWOOD and Mr. WARNER and of other evidence it seems desirable to receive these statements with some reserve. It is easy to declare that a paper is "arsenic free" if the sole test employed has consisted in applying a crude form of Reinsch test to a square inch of it. We should like to be certain that it is realised by the wall paper manufacturer that if he insists upon "arsenic free" colours the colour manufacturer can supply them and that when the term "arsenic free" is applied to wall papers it should signify that if tested by a delicate method such as the Marsh-Berzelius test the arsenic, if present at all, will be found in amounts which for practical purposes may reasonably be disregarded. In our present knowledge such a limiting quantity might perhaps be fixed as one-fiftieth of a grain per square yard and the results to which we have referred show that already the attainment of this limit is a matter which does not present any practical difficulty to certain manufacturers.

Shifting Dulness in the Thorax and the Abdomen.

IT is well that from time to time we should re-examine the evidence on which our opinions are based so that we may be able to give the reasons for the faith that is in us. There is need for this reconsideration of our conclusions in all branches of study and learning but especially is it wise in matters relating to the science of medicine. When a monograph is written on a small section of a subject it is perhaps possible for the author to be certain that he has included in it no statement the truth of which he has not personally proved. When, however, a general treatise on medicine or surgery is written it is obviously necessary for the writer to depend largely on the statements of his predecessors. He gives the views which are current at the time when he writes, except as to a few points where he may have made some original investigations. In this way statements are copied from text-book to text-book, each writer giving it on the authority of those who have written before him, and thus fallacies have been accepted as facts merely because they date from a hoary antiquity. It is therefore very necessary to test our facts from time to time. Many of the mistaken ideas which exist depend on false *a priori* reasoning untested by experiment. A good example of this was the old statement that heavy bodies fall more rapidly than light bodies and no one ventured to question the unimpeachable syllogism on which the statement was based until GALILEI showed by experiment that weight had nothing to do with the rate of falling. Mr. RICKMAN J. GODLEE recently delivered a lecture before the Hunterian Society and in this he drew attention to some erroneous teaching as to the physical signs of the chest and the abdomen. He showed that great variations, unmentioned in the text-books, occur in the position of viscera, as revealed by percussion, according to the attitude adopted by the patient. In order to investigate the resonance on percussion of patients from below when they are in a recumbent position Mr. GODLEE has had made a high table with a net top, so that he can stand underneath and examine the under surface of the body in any desired degree of recumbency. By means of this aid to examination and by other methods he has been enabled to demonstrate several important facts in connexion with the shifting of dull areas.

In any investigations such as those undertaken by Mr. GODLEE it is important to bear in mind that, as Dr. J. MITCHELL BRUCE has pointed out, the skin shifts to a great extent when the attitude is changed and thus a mark on the surface placed to indicate the level of dulness in a standing patient will apparently show a shifting of the dulness if he assumes the recumbent posture. Mr. GODLEE'S lecture dealt mainly with the question of shifting dulness and his conclusions differ greatly from the dicta of most of the text-books. It is generally taught that a dulness due to a pleuritic effusion or to an empyema shifts with position under the influence of gravity. Mr. GODLEE maintains that the dulness resulting from an empyema with no free gas does not shift at all and that the dulness of a pleuritic effusion shifts very little, if at all. If a pyo-pneumothorax be present of course the case is far otherwise and the fluid moves freely. If there is dulness in the back which shifts on placing the patient on his face or upon the opposite side Mr. GODLEE holds that the cause of the dulness is subdiaphragmatic. In support of this contention he cited several striking cases. It is often stated in works on physiology that the lowest part of the pleura, the so-called "pleural sinus," is never occupied by the lung, even at the acme of inspiration. This appears to be a fallacy, for in very thin persons the lung can be seen to descend to the very bottom of the pleural sinus and the pulmonary resonance on deep inspiration may in many cases obliterate entirely the liver dulness in the back. Dr. S. Ringer has pointed out that if a patient who has a dull area in the chest or the abdomen is anæsthetised the extent of dulness diminishes and this may be very striking in a case of appendicitis. The diminution of dulness is probably due to the firmly contracted muscles pushing away the coils of intestine but when anæsthesia has relaxed the muscles the intestine slips in between the inflamed area and the abdominal wall and the dulness disappears. A similar phenomenon is noticeable in thoracic dulness but an explanation is more difficult. This variation of dulness under the influence of anæsthesia has an important practical application, for it points to the absence of any extensive inflammatory adhesions, so that in the case of an appendicitis the surgeon should take care to open the abdomen, not directly over the abscess but at a short distance outwards, so as to minimise the risk of involving the general peritoneal cavity.

Mr. Godlee shows that in a healthy young man in a standing position there is usually very little resonance to be obtained on percussion of the abdomen. It is difficult to percuss out the edge of the liver but some resonance is generally present over the stomach and the cæcum. In the prone position there is still more dulness. The explanation is that in such patients the small intestine contains little gas. In cases of intestinal obstruction with much distension it is impossible to decide with certainty that there is free fluid in the peritoneal cavity, for dulness may be present in the flanks when the patient is lying on his back and yet the upper flank may become resonant when he is turned on his side, although no free fluid be present. There is no doubt about the fact but the explanation is doubtful. Further, Mr. Godlee shows that a shifting dulness is the normal condition of both bases behind and is no proof of the existence of fluid in the pleural cavity. There is much more of importance in this lecture than we have been able to mention or to quote but we have said enough to show how valuable and suggestive the lecture was. We are too ready to accept as certain and finally determined all that we are taught or find in our text-books and a little healthy scepticism is of value if it leads to our re-proving the fundamental data on which our diagnostic art is based. From the wealth of his clinical experience Mr. Godlee has been able to cull many illustrations of the practical value of the facts which he stated and to the lecture itself we refer our readers.[1]

Annotations.

"Ne quid nimis."

A PROPOSED UNION OF THE MEDICAL SOCIETIES OF LONDON.

At the annual general meeting of the Royal Medical and Chirurgical Society held on Wednesday, March 1st, the President, Sir R. Douglas Powell, in his address to the society, spoke of the benefits that would be derived by the profession from a union of the medical societies of London into one Royal Society of Medicine. it must have been derived from the surroundings. 9. However largely affected with the bacillus typhosus, the oysters at no time present to the eye any sign of such infection; they remain in all parts normal in aspect. This is the case not only with the infected oysters kept in sea water but also with the infected oysters kept in the "dry" state. There was only one exception—viz., an oyster derived from a polluted locality, which oyster had been eleven days out of the water. 10. During the time of these experiments (part of September, October, and part of November) the oysters lived quite well in *sterile* sea water frequently changed. There was no alteration noticeable in the aspect of the shell-fish; they remained plump and juicy and capable of promptly and tightly closing the shell. 11. Cockles readily embody the bacillus typhosus present in sea water. While the number of these latter appears at first to diminish in the body of the cockles it soon increases to a considerable degree, for five days after the cockles had been removed from the infected water and kept in clean sand the number of bacillus typhosus exceeded three times the number initially present. Their subsequent diminution proceeded only slowly since even ten days after their removal from the infected water the cockle examined still contained in its body 69,000 bacilli. 12. Mussels also readily embody the bacillus typhosus; in fact, the analysis seems to show that mussels do so to an extent greater than was found to occur in oysters or cockles. As regards the fate of the bacillus typhosus in the mussels these appear to stand between oysters and cockles, since in mussels the bacillus undergoes gradual diminution; this diminution, however, is incomparably slower than in oysters but takes place somewhat more quickly than in cockles.

A LIBEL UPON HOSPITALS.

IN certain numbers of a periodical called the *Wide World Magazine* there once appeared a series of articles by an enterprising person calling himself de Rougemont which dealt, under the guise of truth, with imaginary adventures in Australia and the neighbouring seas. The firm of Messrs. George Newnes, Limited, which firm, we believe, published the adventures of de Rougemont, has brought out a magazine called the *Grand Magazine* in which it seems possible that an admirer of de Rougemont conceals his identity under the title of "A Medical Practitioner." The enterprising gentleman styling himself de Rougemont took in the *Wide World Magazine* and the British Association in his character of a traveller, and in a similar way, surely, "A Medical Practitioner" in an article called "Hospitals: their Use and Abuse," which appears at p. 182 of the *Grand Magazine* for March, has taken in Messrs. George Newnes, Limited. An editorial note prefixed to the article commences as follows: "The writer of the following article, who is well acquainted with the facts and vouches for the accuracy of his statements, points to certain defects in the management of our great hospitals." Let us now give some extracts illustrative of what "A Medical Practitioner" calls "easily verifiable facts":—

> It may be said with perfect truth that the girls and young women who attend the public hospitals gain the possible healing of their bodies [illegible] naked, merely for purposes of demonstration I have myself seen this done some hundreds of times.
>
> Eighteen months ago I was the unwilling witness of an even greater atrocity. A woman was dying of malignant disease of the stomach and the physician under whose *care* she was was delivering a clinical lecture, taking the unhappy woman as his text. In the course of his remarks he mentioned various ways of ascertaining the extent of the stomach, amongst them the method of inflating it with gas and then by percussion mapping out its boundaries. A student inquired precisely how it was done and the physician said he would show him. The patient was thereupon given a solution of bicarbonate of soda and this do [illegible] ic acid. The effect on tl [illegible] understand, for the sto [illegible]. which would have been [illegible] uch more so when eaten out with cancer? She was hours recovering from the effect of this entirely unnecessary experiment, and she died the next day

These atrocities, according to "A Medical Practitioner," are committed more or less "in every hospital recognised as a place of instruction for students," and the editor believes that the person who could write such things is "well acquainted with the facts"! Of course, this statement is a stupid lie, and the firm of Messrs. George Newnes, Limited, ought to be ashamed of giving it currency and of publishing a shameful libel upon hospital practice.

PYROMANIA, A PSYCHOSIS OF PUBERTY.

IN the *Archives de Neurologie* for December, 1904, Dr. Raoul Leroy, assistant physician at the Evreux Asylum, refers to the medico-legally important subject of pyromania in young persons of both sexes, a form of mental disorder which leads to acts of incendiarism. "Whenever repeated fires occur," he says, "in a village or in the country suspicion generally falls on persons of incomplete mental or physical development—weak-minded youths or girls—among the inhabitants and it generally proves to be well-founded." The mental state of such incendiaries, says Dr. Leroy, is peculiar and characteristic. They are weak-minded and are often members of families in which epilepsy, insanity, or alcoholism occurs. Reference is made to the fact that among the peasant population of Normandy, where alcoholism prevails to a high degree, juvenile crimes of the nature of incendiarism are common. These feeble-minded delinquents are prone to set fire to buildings or other objects in revenge against their owners or in some cases merely to amuse themselves with the spectacle. A few cases, says Dr. Leroy, suffer from the influence of an obsession which irresistibly impels them to such acts, such cases forming a special form of insanity to which the term "pyromania" is applied. True cases of pyromania manifest themselves for the first time at the period of puberty. The following typical case is given in illustration of this affection. The patient or culprit in this case was a girl, aged 15 years, a domestic servant, who on three separate occasions had set fire to the house of her master. She was the child of respectable parents and at first no suspicion was entertained of her but on being questioned before the police at the third outbreak of fire she showed much agitation and finally confessed her guilt. "When she had stated the facts fully and was asked if she realised the wickedness of her crime," she replied, "Something supernatural urged me to set the place on fire." Although she was reasoned with and her wrong-doing demonstrated in the clearest manner "she remained unshakable and invariably repeated the same words in justification." She had no reason to hate her master, there was no motive whatever of vengeance that impelled her, only a presumably morbid impulse. The medico-legal inquiry revealed the fact that a highly neurotic hereditary taint existed in the family; the grandfather was a man of excessively violent disposition, a first cousin was liable to periodic attacks of insanity during which he wandered about, the grandmother committed suicide at the age of 62 years, and the patient's mother was a very nervous, emotional, weak-willed woman afflicted with coxalgia. The patient herself was a [illegible] but little intelligence and never could read and write correctly. Her character was excitable, violent, and impulsive, with a total lack of good judgment. At the age of 13 years she developed nocturnal somnambulism, walking all over the house in her sleep and having no recollection of it in the morning. The menstrual periods, which set in at the age of 15 years, were attended with headache, insomnia, and great nervous prostration. On one such occasion she had a hallucination that her bed was surrounded by flames and this was the starting point of her obsessions. Almost daily after this she felt the sudden morbid impulse to set something on fire. It grew stronger though she struggled against it, suffering great mental and physical distress in the process. The morbid obsession occupied her mind to the exclusion of all other ideas and caused such distress and agony that she could resist no longer. Taking a lighted taper she set fire to a packet of waste paper. This was followed by instant relief of distress and an agreeable feeling of satisfaction. These obsessions occurred from time to time and on three such occasions she set fire to outbuildings and parts of her master's house. The medical evidence taken before the magistrate in the trial of this patient showing the occurrence of insane impulses the patient was removed to the asylum. Dr. Leroy concludes that the morbid heredity on both paternal and maternal sides resulted in a brain liable to disorder and readily provoked to morbid impulse (in this case pyromania) on the occurrence of the stresses of puberty, a critical time in mental development.

LEPROSY AND THE LAW IN NEW SOUTH WALES.

THE statistics of the New South Wales leper lazaret at Little Bay, near Sydney, show that there were ten admissions and three deaths during 1903 and that 17 patients remained under treatment at the end of the year. In accordance with his usual custom, Dr. J. Ashburton Thompson, president of the Board of Health, gives copious clinical and etiological notes on the recent cases, one of which, moreover, presents some remarkable features in its social and legal aspects. The patient in question was a man retired from business and in easy circumstances. He was born in New South Wales in 1846 and had travelled all over that State but had never been outside it. When leprosy was diagnosed he made an application to the Board of Health for permission to be segregated in a house of his own under a section of the Public Health Act of 1902 which provides "that such person be ...... detained in such lazaret until released by order of the Board or be isolated in such place and in such manner as the Board directs." For this purpose he proposed to live in a house which stood detached in its own allotment in a suburb of Sydney on a broad road, 150 yards distant from any other house on the same side of the way. This was approved by the Board and the rules by which he was to guide himself while living there were laid down. The Board had used every possible precaution to avoid publicity in this as in every other case but the facts were divulged and the neighbouring property owners protested on the ground that the value of their property would be depreciated by the patient residing there. The house where he was living near by was boycotted and tradesmen refused to supply commodities, so that even food had to be bought at a distance and carried home by the purchasers. The patient was therefore ultimately compelled to take refuge in the public lazaret. The complainants, however, were not content with this result of their efforts but they attempted to obtain such an alteration of the law that it would be made illegal for the future to segregate any leper elsewhere than in the public lazaret. A Bill of which its proposer said: "The Bill provides that in the future the Board must send lepers to a reserve proclaimed by the Government for that purpose,' was read the first time in the Legislative Assembly on July 15th, 1903, and a second time on the 20th of the same month. Dr. Thompson had in the meantime written to the State Treasurer pointing out that the proposed legislation was not justifiable on medical grounds and would occasionally have the effect of producing unnecessary hardship. Having passed in the lower House the Bill reached the Legislative Council on August 20th, was opposed by Sir Normand MacLaurin, and was thrown out. The leprosy returns seem to show that the patient was still in the lazaret on Dec. 31st, 1903.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

THE fifth lecture of the series[1] was delivered by Professor W. F. R. Weldon on Jan. 24th at University College, London, and dealt with the subject of the determinants of heredity. Many writers hold that some form of *material "determinants" passes in the germ* cells from parent to offspring, each group of determinants giving rise to the formation of one specific tissue or part of an organ. The idea of specific determinants was propounded by Mendel and Weismann. Roux and de Vries taught that the karyokinetic phenomena of cell division indicated a qualitative as well as a quantitative division of the nucleus and this idea has been further developed by Weismann. The number of chromosomes in the nuclei prior to cell division varies according to the species of animal and the tissue in which they occur. Hertwig has found in many invertebrates somatic chromosomes in the following numbers—viz., 18, 27, 28, 29, and 36. The worm *ascaris megalocephala* has two and four chromosomes respectively in its two subspecies. Human somatic cells contain 16 (Bardeleben) or 32 chromosomes, while in the sea-urchin the number is 36. There is no correlation, says Professor Weldon, between complexity of cell structure or function on the one hand and the number of chromosomes on the other. In the process of division each rod of chromosomes splits exactly into halves which separate and pass towards the centrospheres at the opposite poles of the dividing cell, so that each daughter cell receives an equal number of halves. The chromatin rods of a germ cell prior to maturation are fewer than the number contained in the somatic cells. Thus the germinal chromosomes in echinus are 18 while the somatic are 36 in number. This, Professor Weldon says, is a general rule. The longitudinal splitting of the beaded rods of chromosomes into slender rods of half beads is the normal process and this has been interpreted by Roux and Weismann as indicating a division which is both quantitative and qualitative of each chromosome. Weismann states that this cleavage process is continuously associated with a differentiation of the dividing parts, certain nuclear determinants being "sorted out" at each stage of division, so that cell differentiation takes place in various lines, leading to the formation of various tissues (nervous, muscular, glandular, sustentacular). In the process of conjugation of sperm and germ cells the centrosome or "archoplasmic substance" which forms the spindle fibres and takes an active part in the mechanics of the process of division is contributed by the spermatozoon. The centrosome is thus a motor mechanism which divides itself into two centrospheres, each centrosphere consisting of a central active corpuscle of protoplasm emitting contractile threads which attach themselves to the split-up segments of chromatin in the equatorial region of the germ cell body. By the contraction of these fibrils the chromatin segments are drawn away from the equatorial region towards the centrosphere at each pole of the cell, after which a septum is developed which completes the division of the cell body into the first pair of blastomeres. This process of cell division is repeated with almost mechanical regularity until the limit of numerical development is reached for the particular group of cells (tissue or part of organ) in question. Such a process as the "sorting of determinants"—that is, of elementary invisible microscopic constituents of the chromosomes postulated by Weismann—is, Professor Weldon thinks, quite irreconcileable with the facts of the equipotential nature of blastomeres in the early stages of cell division and with the facts of regeneration of lost parts, subjects which have been expounded in previous lectures. In normal cell division the chromosomes divide evenly, both in the qualitative and the quantitative sense, so that each of a pair of daughter cells receives at each division equal quantities of paternal and maternal chromatin from the parent cell. The changes which subsequently occur in the different cell lineages derived from the fertilised germ cells are largely due to other factors—viz., the relative positions assumed with regard to each other and to the cell mass by individual cells, and the differences of the incidental stimuli of the environment on differently placed cells (gravity, light and shade, pressure, relative food-supply). Boveri, who has given minute attention to the subject, concludes that it is the protoplasmic differentiation primarily produced by such incidental and environmental factors which determines in turn whether the chromosomes within the cells are to persist along one definite cell lineage as primitive chromosomes or are to undergo secondary differentiation in the variously differentiating somatic or tissue cells. Hence for normal development and perfect embryogenesis a very constant and 'correct" environment is necessary.

[1] Abstracts of the first, second, third, and fourth lectures were published in THE LANCET of Jan. 7th (p. 42) and 21st (p. 181) and Feb. 4th (p. 307) and 25th (p. 512), 1905.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE quarterly meeting of the Medico-Psychological Association was held on Feb. 23rd at the North Riding Asylum, Clifton, near York, by the courtesy of Mr. J. Tregelles Hingston, the medical superintendent. The President, Dr. R. Percy Smith, occupied the chair. A motion was submitted, in which it was proposed by Dr. J. Carlyle Johnstone and seconded by Dr. E. B. Whitcombe "that the period of three years' training for nurses in an institution for the treatment of mental disorders, as prescribed by the regulations of the Medico-Psychological Association, must be served in one institution." A discussion arose upon the above motion, in the course of which different views were advanced. Dr. T. B. Hyslop and Dr. T. S. Clouston opposed the motion on the ground that it would be unfair to intelligent and aspiring nurses who were anxious to succeed and who after entering institutions where the education and training of nurses were inadequate found to their cost that this motion bound them to serve for three years in one institution so that time was lost until they had moved into an institution where adequate education and training could be secured. Moreover, the demand of such a long apprenticeship continuously at one institution was too exacting. Among others who took part in the discussion were Dr. G. M. Robertson, Dr. Ernest W. White, Dr. D. Yellowlees, Dr. T. Outterson Wood, and Dr. F. P. Hearder. An amendment was then proposed by Dr. Outterson Wood, duly seconded, and on a show of hands carried by 21 votes to 10 to the effect that the period of training for nurses should be two years and that it should not be served at more than two institutions. (The object of limiting the number of institutions to two was to discourage the few nurses who were mere "rolling stones.") This was adopted as a substantive motion and carried. Dr. Hyslop read a paper entitled "The Problem of the Insane in its Relationship to Overcrowding and Poverty." He argued that it was the duty of the association to constitute itself, owing to its special knowledge, its status, and its facilities for obtaining correct information, into a committee of inquiry into the subject of pauperism and overcrowding in their relations to insanity and mental degeneration. Collateral matters would legitimately come within the scope of the inquiry, such as the question of alien immigration, tramps and vagrants, and slum life, as also the action of alcohol and diet. An animated and lengthy discussion followed in which the President, Dr. Charles Mercier, Dr. Robert Jones, Dr. Clouston, Dr. T. Seymour Tuke, Dr. Outterson Wood, and others took part. No motion was, however, proposed at the termination of the discussion and the rest of the programme was adjourned to the next meeting owing to the lateness of the hour.

PARATYPHOID FEVER.

THE discussion which took place at the Royal Academy of Medicine in Ireland on Jan. 20th last[1] draws attention to a condition, at present known as "paratyphoid fever," which is not fully recognised. Many cases of continued fever are met with which clinically closely resemble typhoid fever but the blood does not give the Widal reaction and in most of the cases which have proved fatal the lymphatic structure of the intestine has not been involved. Certain observers maintain that instances of true typhoid fever occur without special changes in the intestine but other authorities contend that such cases are really caused by the "paratyphoid" infection. The disease and its relation to typhoid fever have called forth a considerable number of interesting and important contributions. The malady is caused by a micro-organism which appears to occupy a position intermediate between the colon and the typhoid bacilli and presents some of the characteristics of each. Two species of the "paratyphoid bacillus" have been separated, the *alpha* and the *beta*. There seems to be no clinical difference between the action of these two organisms. The symptoms of the paratyphoid infection are in many cases very similar to those which are met with in typhoid fever. The course, however, in the former is usually milder than in the latter and may even be afebrile; moreover fever, when present, may end by crisis. Diarrhœa is common in the paratyphoid infection. The duration of paratyphoid fever varies from 12 to 84 days. Epistaxis is a frequent symptom. Relapses, both first and second, have been recorded. Rose spots and a palpable enlargement of the spleen have been present in about one-half of the reported cases. The pulse is usually slow and irregular. Complications are common and certain of them which are very rare in typhoid fever have been repeatedly noted in paratyphoid fever. In the list are included pleurisy, endocarditis, meningitis, peritonitis, cholecystitis and cholelithiasis, orchitis, phlebitis, osteomyelitis, and others. An absolute diagnosis can be made only when the paratyphoid bacillus is obtained from the blood, the urine, the fæces, or some local lesion. In the light of present knowledge it may be stated that the diagnosis is justified if the paratyphoid bacilli are agglutinated by the blood serum of the patient in a high state of dilution and if typhoid bacilli are not agglutinated by it. The prognosis in paratyphoid fever is favourable. The term "paratyphoid fever" is to be regretted. Unless some definite connexion exists between this infection and that of typhoid fever some other name should be given to the disease. The symptoms of the two affections are certainly similar but the bacterial origin is different, and we should prefer to base the nosology of a fever more on its pathology and bacteriology than on the clinical picture.

LABOUR AND THE FERTILITY OF THE SOIL.

THE King out of his well-known kindness of heart has again given evidence of his sympathy with the genuine unemployed. Encouragement from such an august source is calculated to quicken the efforts of those individuals and public bodies who have power to help those out of work and we may therefore hope for some possible solution of this melancholy problem. Every indication points to our looking to the land as a means of relieving the present stress. If men cannot build, bake, or brew, they can dig and delve. An idle man and untilled land mutually absorb one another. A little arrangement and no able-bodied man willing to work need lack employment. Indeed, out of evil sometimes cometh good and when once men are set to work to develop the land public attention will be drawn in a surprising manner to its fertility and the easy means of maintaining the same. If there is not room in this little island for our surplus workers there is abundant opportunity further afield and Canada is probably the best example that could be quoted. The farmers there are, we understand, ready to take any number of able-bodied men. Only one doubt disturbs us: how long are we to expect the present extraordinary fertility of the Canadian wheat lands to last? There are already ominous signs of shortness of crop and evidence that the essential elements in the soil are "approaching a period." Any sudden failure will mean ruin to farmers who cannot "move on," like the old pioneers, to "fresh woods and pastures new" and privations to the farm hands. We should like to see in the multiplicity of pamphlets issued some figures in regard to the analysis of the soil and some evidence that the wonderful experiments and inventions of he late Sir John Lawes have been appreciated and utilised. "Back to the land" may be wholesome advice but the land must be fertile and kept so by scientific reasoning and application.

THE DEMONSTRATION OF TYPHOID BACILLI IN THE BLOOD OF CASES OF ENTERIC FEVER.

IT has long been known that the bacillus typhosus may be found in almost any part of the body, and may set up morbid changes there and also that cases presenting the clinical features of typhoid fever may occur without the characteristic lesions in the intestine. The occurrence of a typhoid septicæmia has therefore been inferred and proved by the discovery of the bacillus in the blood of the patients. Within recent years a large number of investigations have been made by different observers using different methods to determine the frequency of the occurrence of the bacilli in the blood, the general result of which seems to be that they occur in almost every case and that typhoid fever even in mild cases is a true typhoid septicæmia. The question is carefully discussed by Dr. Jean Perquis of the Faculty of Medicine of Paris in an exhaustive monograph[1] embodying his own researches and including a critical investigation of the value of "hæmoculture" as an aid to diagnosis compared with that of the Widal serum reaction. The first observer to find the bacilli at all frequently was Castellani[2] who obtained them in 12 cases out of 14. The method which he adopted was to use a large quantity of the nutrient medium in order to lessen the bactericidal power of the serum of the patient. He used five or six flasks containing 300 cubic centimetres of ordinary peptone bouillon made slightly alkaline, adding to them quantities of blood varying from five to 50 drops, then putting them in the incubator at 37° C. Positive results were obtained in from 12 to 36 hours. Dr. Perquis has modified this method as follows: the arm of the patient is prepared as if for venesection, especial care being taken to insure the disinfection of the skin, and the spot at which the syringe is to be inserted is touched with a fine cautery point to insure destruction of all organisms within the skin. The blood when withdrawn is put into sterile tubes and defibrinated, after which about from 15 to 25 drops are inoculated into two flasks, each containing from 80 to 120 cubic centimetres of peptone bouillon; these are placed in the incubator at 37° C. and examined every 12 hours. He claims that this method is cheaper and more trustworthy than that of Castellani, the defibrination being especially important. The method was applied in 40 cases of typhoid fever, of which details are given, some being very severe, others mild in type, while in three there was a relapse. Positive results were obtained in 38 cases, while two were negative; these were, however, of great interest, since in them the blood was not investigated until after the twentieth day and it was found in the other cases that the later in the course of the disease the blood was taken the slower the growth of the organism was, while in the cases with relapse the bacillus disappeared after the primary attack to reappear during the course of the relapse. So far no constant relation has been found between the occurrence of the organisms in the blood and the occurrence of the Widal agglutination reaction, although the increasing difficulty of growth of the organism from the blood in the later stages of the disease suggests the development of more and more bactericidal substances in the serum. The occurrence of the bacillus in the blood is an early incident in the disease. Dr. Perquis found it in one case as early as the second day of the fever, Busquet found it in the fourth, and Hewlett, Courmont, Widal, and Pinat on the fifth. The bacilli are generally supposed to disappear from the blood towards the end of the third week but they have been found by Courmont on the twenty-eighth day, by Rnata on the thirty-fourth, by Pinat on the thirty-sixth, and by Auerbach and Ungar on the forty-second; but all these cases were of severe or fatal character. Comparing the utility of this method with that of Widal Dr. Perquis admits that the latter is easier, more rapid, and more convenient for ordinary cases, but he points out that the method of hæmoculture affords valuable information in the very conditions where Widal's reaction fails—namely, in the early days of the disease and in those cases where there has been a previous typhoid infection. Widal's reaction, moreover, cannot be regarded as an absolute proof of the typhoid nature of any given case, whereas the demonstration of the organism in the blood is conclusive. The main disadvantage is the time necessary for the method, which, allowing for the time required for control cultures when a positive reaction is obtained, varies from 36 to 60 hours. Dr. Perquis's work forms a valuable contribution to the literature of typhoid fever since it confirms the view that the disease is in all cases a general infection, includes a simple and practical method of culture of the organism from the blood, and demonstrates that the organisms may be obtained from cases not giving Widal's reaction.

PUBLIC HEALTH IN BRITISH GUIANA.

MUCH information relative to the various departments of the public medical service of British Guiana will be found in the recently published report of Dr. J. E. Godfrey, the surgeon-general of the colony. The principal institutions for the reception of patients are the public hospital in Georgetown, with 700 beds; the public hospital in New Amsterdam, with 150 beds; the lunatic asylum; and the leper asylum. Besides the two hospitals above mentioned there are also smaller ones in Suddie, in Bantica, and in Morawhanna. During the year ended March 31st, 1904, there were treated in these five hospitals 17,617 in-patients with 1728 deaths, while the number of out-patients for the same period was 67,189. Among the in-patients some of the more prevalent diseases shown in the statistics were as follows: dysentery, 513 cases, with 137 deaths; malarial fever, 3029 cases, with 92 deaths; pulmonary tuberculosis, 576 cases, with 233 deaths; diarrhœa, 541 cases, with 102 deaths; Bright's disease, 667 cases, with 255 deaths; ankylostomiasis, 428 cases, with 48 deaths; and filariasis, 176 cases, with five deaths. In the lunatic asylum 184 patients were admitted during the year and there were 104 deaths, the daily average number under treatment being 773. In the leper asylum 107 patients were admitted 51 were discharged, and 76 died, the daily average number under treatment being 424. The birth-rate and the death-rate of the whole colony were respectively 29·3 and 28·9 per 1000, the deaths of infants under one year of age being at the rate of 205 per 1000 births. The death-rate for the city of Georgetown and its environs, exclusive of the country patients at the public hospital, was 44·1 per 1000, the deaths of infants under one year of age being at the rate of 334 per 1000 births. Small-pox of a mild type was prevalent throughout the colony; 1821 cases were reported and 1434 cases were treated at the isolation hospital; there were 14 deaths from the disease—i.e., a mortality of less than 1 per cent. A few of the small-pox patients were aboriginal Indians, one of whom gave her age as 112 years and several claimed to be well over 70 years. Dr. Godfrey gives a short account of endeavours which are being made, but with only limited success, to induce trained nurse-midwives to settle in the villages and rural districts.

CHYLOUS ABDOMINAL CYST.

In the *Boston Medical and Surgical Journal* of Feb. 9th Dr. M. H. Richardson has reported a case of the rare condition of chylous cyst of the abdomen. A boy, aged 11 years, was referred to him in October, 1904. A practitioner sent a letter with the opinion that there was fluid of some kind in the abdomen which was not free in the peritoneal cavity. In the summer of 1903 fulness in the abdomen, especially at the navel and on the right side, was first noticed. There were nervous symptoms and at times acute indigestion. In the first week of October, 1904, there were nausea, vomiting, and diarrhœa for a number of hours but there was no pain. On examination the boy was found to be thin and cachectic with a very prominent abdomen. The lower ribs were pushed outwards. The abdomen was much distended and full of fluid which appeared to be free. The temperature was 100° F. Dr. Richardson diagnosed tuberculous peritonitis and opened the abdomen by a small incision between the umbilicus and the pubes. On incising the peritoneum he came upon a white fragile cyst which filled the peritoneal cavity. It was covered with small blood-vessels, most of which ran transversely. The incision was enlarged sufficiently to admit the hand. The cyst was then seen to be retroperitoneal and to extend up under the liver and to the right. It seemed at first to be a hydronephrosis; close to its upper part the right kidney was felt. Dr. Richardson decided to attempt enucleation of the cyst after tying the vascular peritoneal covering in sections. The cyst was then easily separated but the thin wall was ruptured here and there allowing a milky fluid to escape. It was emptied through an incision and the contents amounted to a gallon. The sac was carefully separated from all attachments, the dissection being made with blunt curved scissors and gauze. The ascending colon, the hepatic flexure of the colon, and the vertical portion of the duodenum were successfully separated. Whether the cyst was a dilatation of the receptaculum chyli or of one of its tributaries could not be made out. The boy rapidly recovered. He gained flesh and strength and was restored to perfect health. Microscopic examination of the cyst wall showed that it was composed of fibrous tissue. The contents were a milky liquid of the specific gravity of 1020, containing abundant albumin. On testing with osmic acid a slight blackish discolouration was obtained. Microscopic examination showed fine granules and numerous large granular corpuscles. Dr. Richardson emphasies the fact that before the operation the diagnosis of tuberculous peritonitis seemed quite certain and that relief of the condition present was possible only by operation. In many other cases of apparently hopeless disease of the abdomen he has operated and found an easily remediable condition. The moral is that in such cases the surgeon should explore the abdomen unless incurable disease can be certainly diagnosed.

THE PUBLIC HEALTH BILL OF THE BRITISH MEDICAL ASSOCIATION.

We have received a copy of this short and simple Bill the main objects of which are to insure that none but those properly qualified shall be appointed as medical officers of health or sanitary inspectors and to give to all such officers and inspectors similar security in their tenure of office to that enjoyed by Poor-law medical officers and metropolitan medical officers of health. As the law stands no qualification is required for a sanitary inspector except in London; and as a general rule a medical officer of health or sanitary inspector is appointed from year to year only and thus has no true security of tenure. Poor-law medical officers and metropolitan officers of health are not appointed for limited periods only and are removeable only by, or with the consent of, the Local Government Board. "The duties of medical officers of health and inspectors," says the memorandum of the Bill, "are so important and responsible that they ought to be entrusted only to fully qualified persons whose position is satisfactorily secured." All our readers know our views upon this matter. No one with any knowledge of the local government of this country—apart from all medical bias—can doubt that the public health should now be placed in the care of a properly paid service the members of which should enjoy security of tenure and should only feel responsible to their authorities for any action that they may desire to take in the public interest.

AMAUROTIC FAMILY IDIOCY.

Since the description of amaurotic family idiocy by Sachs (1887) the occurrence of this disease has been noted by an increasing number of observers, but its pathology has only recently been studied. Dr. James McKee, professor of children's disease at the Philadelphia Polyclinic, has published in the *American Journal of the Medical Sciences* for January an interesting clinical and pathological study of a case. The patient was an infant, one year old, the child of healthy parents. There was no history of tuberculosis, syphilis, or insanity on the father's or mother's side. The child was considered a normal baby but he suffered much from constipation and took cold easily. At the age of one year he showed a square rachitic head, craniotabes, and a widely open fontanelle. He had a marked lumbo-dorsal curve and showed beaded ribs and both enlarged liver and spleen. The muscles of the neck were weak. The child was mentally backward and never learnt to speak. The rachitic symptoms improved slightly under treatment but during the early part of the second year blindness gradually set in. The child "took no notice of his surroundings and did not use his arms for grasping." Ophthalmoscopic examination showed the characteristic retinal lesion of amaurotic family idiocy—pale areas of atrophy in the macular region of the eye. The upper and the lower limbs grew spastic with the progress of the disease and "claw-hand" showed itself. The great toe extended and the other toes flexed as in Babinski's symptom. The tendon reflexes were exaggerated and ankle clonus prevailed. Both Babinski's reflex and excess of plantar reflex were recorded. The pupils were dilated, unequal in size, and did not respond to light. There were slow nystagmoid movements of the eyes. Consciousness was dulled and the child was exceedingly somnolescent. The respirations were 36 per minute, the pulse was 136, and the temperature (in the rectum) was 95·6° F. The child eventually died from adenopathy, pneumonia, and bronchitis at the age of two and a half years. Professor McKee records the curious fact that since Sachs's observations it has been noted that all recorded cases of this affection were members of the Jewish race, a remarkable instance of racial proclivity. The disease is essentially one of infancy and affects girls more than boys in the proportion of 2 to 1. Its onset is generally between the second and tenth months of infancy. "In amaurotic family idiocy," concludes Professor McKee, "the cerebral development, till then normal, ceases at a very early age. The cerebral cells degenerate and idiocy results." That the disease should be common in the progeny of a hard-working self-denying race, a race in which the neuropathic factor is prominent, is, says Professor McKee, intelligible. Microscopic examination showed increase in size and a globular condition of the retinal ganglion cells and an entire absence of Nissl's bodies. The optic nerve showed absence of myelin in many of its fibres and the neurolgia of the nerve was increased (simple degeneration). The pathology of amaurotic family idiocy, its clinical characters, and its special proclivity to affect the Jewish race, are now fairly well known; its etiology still awaits discovery.

STERILISED MILK DEPÔTS IN PARIS.

Dr. Richard Caton, on behalf of a special subcommittee of the Liverpool town council, which has devoted considerable attention to the question of providing sterilised milk, has recently issued a memorandum in which he gives an account of his visit to some of the principal institutions of Paris in which sterilised milk is prepared and distributed for the benefit of the children of the poor. The method, he points out, is much more widely diffused in France than in England, being in active operation in no less than 65 French towns (as well as in 36 in other parts of Europe). In no place was he able to find that the system was a success commercially. Though, however, the adoption of the method is a considerable cause of expenditure—in many places the milk being given gratuitously and in others sold at half price—the results in saving life are so important that in no place is there any intention of abandoning the method on the score of cost. The sterilised milk is distributed at hospitals or dispensaries and every child receiving it is seen and examined from time to time by the medical officers of the institutions. According to Dr. Caton's observations two different types of distribution exist in Paris. The so-called "Goutte de Lait" method is carried on at the Belleville Dispensary which is situated in the midst of the poorest population of Paris. The milk is derived from a farm (where a sterilising apparatus is kept) in Normandy. The milk is sterilised at 108° C. and under pressure. The milk keeps perfectly good for a week or more and so some economy of distribution is effected. The milk is sterilised as soon as it is obtained from the cow. Dr. Caton suggests that if it were possible to obtain the milk from a farm close to Liverpool and to have the sterilising done at the farm Liverpool might secure the same advantage that is enjoyed at the "Gouttes de Lait." This system of Dr. Variot has been in operation for ten years and he is thoroughly satisfied with it; he has never seen a case of infantile scurvy attributable to the milk and he states that in about 4 per cent. of the children sterilised milk does not agree, that in a few its use is followed by anæmia, and that in others it causes constipation. In the other form of distribution in Paris, carried out amongst other places at the great Charité Hospital, the cans of milk are purchased from the ordinary dealer and the sterilisation takes place at the depôt at 208° F. in the hospital from which the milk is distributed. Dr. Caton points out that the one respect in which both these methods of distributing sterilised milk is superior to ours is in the fact that every child is under medical supervision. It may often happen, he adds, that some other ailment in addition to dyspepsia is present and in that case the giving of sterilised milk may not meet the circumstances fully. Though there may be great difficulties in providing medical attendance at the milk-distributing depôts in this country the question arises, he thinks, whether in bad cases it would not be well as a principle of routine to advise the mother to seek medical advice for the child.

PAPAIN.

In a paper published in the *Annals of Botany* for January, under the heading of "The Proteases of Plants," Professor S. H. Vines records the results of some interesting experiments on the action of papain. Papain is the dry powder prepared from papaw, the "milk" obtained from carica papaya. It would appear that papaw has been somewhat difficult to obtain owing to the fact that the Americans took steps to secure for themselves all that could be found. It is now, however, "an open article" on the market in this country. The samples of commercial papain tested by Professor Vines were obtained respectively from Messrs. Christy, Finkler, and Merck. The action on fibrin of these different samples of papain was not uniform, Christy's proving to be the most active. All the samples of papain tested, however, proved capable of effecting complete proteolysis or, at any rate, peptolysis in various degrees. The action was more vigorous in the presence of hydrocyanic acid than in the presence of toluol and it was, on the whole, stronger in the alkaline than in the acid liquids though the difference was not great. With regard to autolysis, the results bring out again the specific differences in activity between the three samples of papain. The most striking tryptophane reaction was given by Finkler's papain, on account, probably, of its containing the largest amount of readily proteolysable proteid. With respect to the reaction of the liquid, Christy's and Merck's samples gave better results in acid than in alkaline liquids, whilst Finkler's was more active in an alkaline than in an acid medium. Experiments were made also in which the result could be compared between the fibrin-digesting and the peptolysing activity of the papain in each case. The results go to show that the various samples of papain experimented upon differ widely in their general proteolytic activity and in their relation to acid and alkali as well as to the various antiseptics employed. "One thing at any rate," concludes Professor Vines, "is made clear, that the last word as to the properties of papain will not have been pronounced until a series of careful observations shall have been made with perfectly fresh materials so as to avoid all those modifications that must necessarily accompany the preparation of the varieties of dried papain which have hitherto been used for investigation." The interesting conclusion is suggested that papain contains a fibrin-digesting but not peptolytic protease of the nature of pepsin as well as a peptolytic but not fibrin-digesting protease of the nature of an erepsin. If this be so it will be the first clear demonstration of the existence of a pepsin in the vegetable kingdom. The experiments, though they may not absolutely establish this conclusion, at least indicate a method by which a physiological analysis of possible mixtures of enzymes may be effected. Probably by the application of this method to the fresh juice of the papaw the question will be settled for that plant. In the meantime, Professor Vines is investigating other plants and has already obtained some confirmatory results in the case of the hyacinth bulb, of the pineapple, and of yeast. In the early "sixties" Mayne Reid wrote a book called "Bruin," in which he gave an account of a "barbecue" held in the Southern States. One of the features of this was an ox roasted whole upon a kind of gridiron made of papaw wood, the sap of which Mayne Reid said had for years been kownn as imparting a peculiar tenderness to meat with which it came in contact.

FATAL RESULT OF A FALL OUT OF BED.

IN the *Journal of the Royal Army Medical Corps* for December, 1904, Major H. S. Peeke has reported a striking illustration of the fact that a fatal injury of the head or neck may result from a very slight cause. A private was taken to a military hospital on a stretcher at 1 A.M., complaining of pain in the neck and inability to walk. He was sober. A comrade occupying the next bed stated that about midnight the patient, who had retired early, rose, sat up in bed, lost his balance, and fell over on to the floor on his head. This statement was corroborated by the patient. Examination showed tenderness and pain in the neck and complete motor and sensory paralysis of the lower limbs. The temperature was 99° F., the pulse was 65, and the respirations were hurried and diaphragmatic. He was placed on a water bed and the pain was relieved by hypodermic injections of morphine and cold applications to the neck. The dyspnœa increased and he became comatose and died on the following morning. At the necropsy the body was found to be heavy and muscular. An incision was made from the occiput to below the seventh cervical vertebra, exposing the spinous processes. On inserting the finger a spinous process was found detached. There was a fracture through the base of the fifth cervical spinous process. There were also extensive hæmorrhage and rupture of the dura mater and anterior spinous ligament. The cord was not pressed on by bone but pressure from the hæmorrhage and from inflammatory effusion evidently was the cause of death. As the bed was only 18 inches from the floor fracture of the spine had not been suspected. It was thought that the patient was suffering from concussion of the spine or from hæmorrhage causing pressure on it. Therefore no operation appeared to be indicated and a rapidly fatal injury was not anticipated. The paraplegia at first extended as high as the middle of the breast. From the situation of the injury paralysis of the upper limbs might have been expected but they lost scarcely any power until just before death.

CHLORÆTHOFORM.

THE name chloræthoform has been given to a new anæsthetic containing chloroform and a small proportion of ethyl chloride suggested[1] by John Wade, D.Sc., and Horace Finnemore, A.I.C., of the chemical and pharmaceutical departments at Guy's Hospital. It has long been noticed that chloroform prepared from acetone is inferior in anæsthetic properties to chloroform derived from alcohol; with the former the patient shows a tendency to cough and to hold the breath, while the prolongation of the time of induction increases the risk of administering an overdose. A series of careful fractional distillations gave the writers the clue to this difference, for whereas acetone chloroform begins to distil at 55° C., that from alcohol begins to distil at 54° C. The fraction distilling at from 54° to 55° C. was proved to be ethyl chloride, which is present to the extent of about 0·05 per cent. and is formed during the process of manufacture by the action of chlorinated lime on alcohol. It is not formed, however, in the preparation of chloroform from acetone. As ethyl chloride induces anæsthesia rapidly, thus removing the irregularity of breathing and diminishing the time of induction, the conclusion was drawn that the difference in anæsthetic effect between the two kinds of chloroform is due to ethyl chloride. A small quantity of ethyl chloride was therefore added to chloroform prepared from acetone and the mixture was proved clinically to be equal to chloroform derived from alcohol. In a later note[2] the writers remark that pure chloroform acts rapidly and in a trustworthy manner in perhaps four cases out of five but the risk of accident is always present. This risk, it is probable, is less with chloroform made from alcohol. The 0·05 per cent. of ethyl chloride present in alcohol-derived chloroform is not sufficient, however, to eliminate all uncertainty and the addition of a further quantity is recommended. Chloroform derived from acetone mixed with 0·25 per cent. of ethyl chloride is stated to act satisfactorily and to give as good or better results than does chloroform made from ethyl alcohol.

THE CORRECTION OF LOCAL BIRTH STATISTICS.

IT is one of the anomalies of our modern methods of local self-government that, after considerable circumlocution, public bodies have to obtain at a price from local registrars facts which have already been gleaned at the expense of the public. Thus, at present, the medical officer of health must pay considerable sums out of the local rates in order to discover and to classify the causes of death of citizens within his district. His is often the first medical eye to see the record of "uncertified deaths," and occasionally after much delay he discovers a case which should without doubt have been promptly reported to the coroner. With the information so acquired the medical officer of health is enabled to apportion to their appropriate localities the deaths occurring away from home; this correction is an item of no small moment if his local sanitary authority has within its jurisdiction several public institutions for the care of the sick and the dying. Lately it has been recognised that birth statistics are vitiated from a similar source, for many strangers are delivered in lying-in homes and infirmaries for the poor, thus unduly raising the local birth-rate. The recognition of this fact led to a desire that sub-registrars should for a small fee issue to the medical officer of health a return of the residence of all such mothers. For a time this inexpensive and unofficial system was practised, until the Registrar-General issued a circular to his registrars instructing them that in future if a return of all the births were desired they may exact for it the same remuneration as in the case of deaths. This instruction appears to have been the unforeseen outcome of a resolution of the public health committee of Southwark passed in October, 1904, and circulated among the other borough councils in London. It is evidently to the interest of sub-registrars to insist on a high fee for limited returns in the hope of securing a request for complete information, and already 14 metropolitan local sanitary authorities have deemed it wise to order a full weekly return. It is found in practice that maternity institutions are unwilling to afford the necessary information to the medical officer of health direct and thus it appears to be a wise innovation to receive official details of the current births. Beyond the mere correction of the statistics of birth which this periodical return will effect, provided, of course, that there is a general interchange of information, the adoption of such measures should facilitate and check the investigation of the local prevalence of puerperal fever and of infant mortality as well as afford evidence of the existence of secret lying-in homes with their associated illegitimate births; it should also aid the working of the recent Midwives Act.

THE INTERNATIONAL CONGRESS OF MEDICINE AT LISBON.

IN connexion with the Fifteenth International Congress of Medicine to be held at Lisbon in April next year Messrs. Thomas Cook and Son have chartered a first-class ocean passenger steamer to convey members of the Congress and their friends from London. The vessel will be moored near the quay and in view of the pressure on hotel accommodation usual on such occasions will be used as a floating hotel during the period of the Congress—April 19th to 26th—an arrangement which will doubtless be appreciated by delegates.

THE FUTURE OF THE LONDON MEDICAL SCHOOLS.

UPON the moving of the annual report at the Court of Governors of Middlesex Hospital last week Dr. J. Kingston Fowler, senior physician to the hospital and dean of the Faculty of Medicine in the University of London, made a most important speech. His words arose out of the existing position at Middlesex Hospital, as one of the smaller medical schools of the metropolis, but they have a significance for every London medical school and, indeed, for everyone concerned in the future developments of the medical profession. Referring to the admitted gross abuse that exists in the out-patient departments of the London hospitals—an abuse by no means confined to the metropolis—Dr. Fowler mentioned an extension of the provident dispensary system as being the solution of the present position. By utilising the out-patient departments of hospitals as consulting-rooms for the poor and making the provident dispensaries feed the out-patient departments only with suitable cases two things would be at once gained. The general practitioners would no longer feel that the gratuitous treatment of all and every case by the hospitals was subjecting them to unfair rivalry, while the out-patient departments would only receive in *bulk* the number of cases that they were able to treat and in *quality* the kind of cases that they ought to be asked to treat. From this subject Dr. Fowler passed to a consideration of the present critical position of many of the London medical schools. He took it for granted that his audience was acquainted with this position owing to the report of Sir Edward Fry's committee which had been so recently published.[1] That report must have convinced many who were still doubtful that it was not only absurdly uneconomical but practically impossible for the 12 separate medical schools of London each to support a teaching staff able to deal completely with all the ancillary subjects and possessing all the necessary laboratories and class-rooms implied. The University of London will, it is hoped, soon possess a central school of science where every medical student can pursue the studies antecedent to his purely professional curriculum, but money, much money, is still wanted before that time arrives. But in the meantime the situation at some of the hospitals is acute and the number of medical students in London, despite the unrivalled clinical material of the metropolis, is rapidly diminishing. Dr. Fowler, who is in accord with many of those best acquainted with educational matters, considers that during the interregnum University College, London, and King's College, London, being definitely separated from their hospitals should form centres for teaching the ancillary sciences. This is the view that is supported by an influential group of London teachers, and, as is well known, steps have already been taken to give effect to it. There are contrary opinions upon the point, but such clear pronouncements as have already come from Dr. Fowler will go far to create a trust in the University of London and general agreement with the Dean of the Medical Faculty of that University.

A FATAL case of plague occurred in Brisbane on Jan. 2nd, being the first case since Sept. 15th, 1904. Up to Jan. 21st no other case had been reported but from Jan. 6th to 21st 1730 rodents had been destroyed and 861 had been bacteriologically examined. Of these latter three rats were found to be infected. As regards the Cape Colony the medical officer of health of the colony states that for the week ending Feb. 4th the condition of the colony as to plague was as follows. At Port Elizabeth no case was discovered but of 209 rodents bacteriologically examined 1 rat and 3 mice were found to be plague-infected. At East London 1 native male found dead was considered as being a "case suspicious of being plague." There were 301 rodents and 1 cat examined, of which 1 mouse was plague-infected. In other districts no case of plague in man or other animal was found. In the Mauritius 1 case of plague and 1 death were reported during the week ending Feb. 23rd.

THE adjourned discussion at the Royal Medical and Chirurgical Society on the Subsequent Course and Later History of Cases of Appendicitis after Operation will be held on Tuesday next, March 7th, at 5 P.M. Sir Richard Douglas Powell, the President, will open the discussion and will be followed by Dr. H. P. Hawkins, Mr. C. B. Lockwood, Mr. W. H Battle, Sir William H. Bennett, Mr. A. W. Mayo Robson, and other speakers. Some further statistical tables will be provided at this adjourned meeting in addition to those which were provided at the meeting on Tuesday last. A demonstration with the epidiascope will be given by Mr. Lockwood. The change from the usual hour of meeting may be reckoned as an experiment, made in the belief that the majority of the Fellows would prefer the earlier hour.

ON the occasion of Dr. F. T. Roberts's resignation of the post of physician to University College Hospital, which he has held for more than a quarter of a century, his former house physicians are arranging to entertain him at dinner. Dr. F. W. Mott will take the chair and twenty-five of Dr. Roberts's old house physicians, including Mr. Stonham, Dr. Walter W. H. Tate, Mr. Percy Flemming, Dr. F. R. Blaxall, and Dr. T. Wilson of Birmingham, have already signified their intention to be present. The dinner will take place on March 29th. Further information can be obtained from Dr. Bertram L. Abrahams, 14, Welbeck-street, W., or Mr. R. G. Elwell, University College Hospital, W.C.

WE have received a cablegram from Professor W. Osler asking us to repudiate for him words that he has been described as using in his farewell address to the students of Johns Hopkins University. Professor Osler, in a speech which seems to have been considerably misunderstood on both sides of the Atlantic, referred to a humorous suggestion in a novel, but expressed no views of his own, as to the chloroforming of persons who have reached the age of 60 years.

THE annual clinical debate of the Chelsea Clinical Society will take place on March 14th and 21st in the Chelsea Dispensary, Manor-street, King's-road, London, S.W. The debate will be opened by Mr. W. A. Lane and amongst the speakers announced are Dr. W. Collier (Oxford), Dr. F. J. Smith, Dr. H. Campbell Thomson, Dr. W. H. Goddard, and Dr. Leonard Williams.

---

[1] THE LANCET, Feb. 25th, p. 520.

Professor Sheridan Delépine will open a discussion upon the causes of the increased prevalence of anthrax in Great Britain at a meeting of the Incorporated Society of Medical Officers of Health to be held at 9, Adelphi-terrace, Strand, London, on March 10th, at 7.30 P.M. The chair will be taken by the president of the society, Dr. J. F. J. Sykes.

A PRESENTATION of a testimonial will be made to Dr. W. W. Ireland in the new library of the Royal College of Physicians of Edinburgh to-day, Saturday, March 4th, at 4.30 P.M., on the occasion of the fiftieth anniversary of his medical graduation.

THE MEDICAL MAN AS EXPERT WITNESS.[1]

BY W. B. RANSOM, M.A. CANTAB., M.D. LOND., F.R.C.P. LOND.

THE laws that of late years have been passed for the better protection of workmen from injury or disease produced by their work and the increasing tendency of all members of the public to fix responsibility upon and procure compensation for mishaps that befall them from others, whether individuals or companies, have undoubtedly led to a great increase in litigation in which medical evidence plays an important, if not a predominant, part. And however beneficent this tendency may be, in that it procures employment for a deserving body of men, it cannot be denied that the result is not altogether satisfactory to the medical men, the plaintiffs, or the defendants. The lawyers alone may possibly benefit from the complex mixture of medicine and law which is not proving restorative to either the physical or moral health of the rest of the community. While the whole blame for this state of affairs cannot fairly be laid at the door of the medical profession, yet I fear the attitude we have generally taken up when appealed to for expert opinion in connexion with litigation has not, as was hoped, greatly helped to the right solution of disputed points, has not simplified the administration of justice, and last, but not least, has not conduced to the dignity of our profession as one of science and honour. Let me, however, here state that in what I have to say I make no claim to purer ethics or a higher code of honour than the rest of my brethren and that although I think that often they have adopted an unfortunate attitude and found themselves in a false position, yet I believe that it is not from a blunting of the moral sense but from a mistaken notion of what honour requires from them.

That there are unscrupulous and venial men among us, as there are in all professions, is undoubtedly true, but of them I here take no note. We are, I believe, as a body neither better nor worse than other men of liberal education and have a sense of honour at least as acute as the average citizen. And yet things are not right. We need not go so far as the well-known classification of the followers of Ananias into liars, damned liars, and expert witnesses, but it must have struck many as a curious fact that while in an ordinary consultation it is the rarest thing in the world for medical men to differ, in the witness box they never agree. In the drawing room, talking to the anxious friends of the patient upstairs, Dr. A indorses the diagnosis and delicately praises the treatment of his friend Dr. B, but in the county court he exposes to an indignant public the superficiality of his observations and the fallacies of his conclusions, insinuating at the same time the profound importance of his own vast experience. Dr. B naturally gives him a Roland for his Oliver and so the public are impressed with the accuracy of medical science and the impartiality of its exponents. The same pleasing spectacle is seen where we have a number of more or less eminent medical men on either side. To a certain extent there may be different testimony about matters of fact but to a much greater degree the differences turn on the relative significance of observed facts and in the absence of anything like mathematical exactitude in the present state of medicine there is here ample scope for the ingenuity of the witnesses. Thus a sarcoma is found in the abdomen of a man who alleges that he strained himself lifting a piece of coal. The medical men on the one side rake up all the cases in which a growth has followed an injury and suggest to the jury that nothing is more likely to occur, while those on the other pour scorn on the notion and discourse learnedly on cancer as a parasitic disease or a miscarried germ cell. Not long ago some distinguished and honourable medical men persuaded a jury that a man who died thin and pale succumbed to pernicious anæmia caused by an injury in the pit over two years previously. I venture to think that they would not have given that diagnosis or arrived at that etiology in an ordinary consultation in the patient's house. In another case of pain in the back the court was edified by the medical men on one side swearing to the existence of periostitis of the sacrum, which was flatly denied by their opponents. In those frequent cases of "railway" and "miners'" spine the opposing confident diagnosis of organic and functional disease, or even malingering, can always be counted on to puzzle a jury. The action of a sick club which, being dissatisfied with the continued backache of one of their members, called in a veterinary surgeon and had him examined before them is more to be commended than going to law. "Why, man," said the veterinary surgeon, "you've got rinderpest; you'll have to be shot!" The man bolted home. "Fetch out my pit clothes," he said to his wife, and went to work the next day. The result of these scenes in court, of course, is that the medical evidence is more or less ignored and the judge and jury form their own opinion on other grounds. The labour and cost of collecting the so called expert evidence are wasted truth is not furthered, and an honourable profession is thrown into contempt.

Now what is the reason for this lamentable position in which men of at least average honour and intellect find themselves? The answer is that it arises from the predisposition and temperament with which each approaches the case. It is an obvious fact that it is not the intellectual powers which mainly decide what view a man will take of most problems, at least of those other than mathematical. Whither our guesses at truth will lead us depends on the [illegible] The same facts were at the disposal of Cardinal [illegible] encer, and perhaps [illegible] Yet the same facts [illegible] cology. The same [illegible] to flatly [illegible] common [illegible] Arthur Balfour agree with Mr. John Morley. There must be some radical difference in temperament which leads them to draw such different conclusions from the same facts. What [illegible] excites the predisposition of [illegible] n expert witness? It [illegible] to do his best for the [illegible] mself as an advocate, bound to work up the case from the one point of view, leaving the opposition to find the weak spots in his armour. He imagines himself a medical lawyer whose duty it is to defend his client. This is undoubtedly a code of honour, but it is, I hold, a wrong code and one which has led to disastrous results. I venture to assert exactly the opposite, that the medical man, when consulted as a scientific witness, is not concerned as to which side wins, but has merely to testify to the exact facts and the conclusions logically deducible from them with as near an approach to mathematical accuracy and clearness as he can and entirely without regard to the success or failure of the party which pays him. The scientific expert is not called in to judge the case or to exhibit human sympathy or the reverse; he should be merely an instrument of precision to exhibit the true state of affairs to judge and jury. He is the microscope which reveals things invisible to the common eye, the balance of delicate poise; but if the lenses distort or if the weights be untrue he is worse than useless to the common sense. As the medium of truth he must sink his personality; of predisposition there should be none; his temperament must not come into court.

---

[1] A paper read before the Nottingham Medico-Chirurgical Society on Feb. 15th, 1905.

Yet how can this be when Drs. A, B, and C are asked to report for one side knowing that Drs. D, E, and F are doing so for the other and all their *amour propre* is excited to make a valiant effort to minimise the value of the facts and ridicule the conclusions of their opposing colleagues? The climax of absurdity is reached when each side permanently retains a medical man to fight its claims. The medical men in such a position are advocates, able and honourable advocates it is true, but cannot be looked upon as expert witnesses.' That each side should have such expert advice is fair enough but it should not come into court as an expounder to the laity of scientific truth.

The present methods of adjudicating these cases are in short fundamentally rotten and stand self-condemned by the pitiable scenes that occur in our law courts and the general travesty of justice to which they lead. The system of Crown referees was intended to avoid this state of things, but for some mysterious reason judges have ignored their existence. Either their activity must be called into being or in some other way independent technical exponents of truth must be found and the scientific expert witness no longer be mixed up with the medical advocate.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 3, 1827.

TO THE
RIGHT HON. ROBERT PEEL, &c., &c.
(From THE TIMES *of February 26.)*

SIR,—The high ministerial station which you deservedly occupy, must often expose you to various kinds of applications respecting the condition and management of our national institutions, and also to personal or partial interference about their several real or pretended interests. In all such instances you must perceive the fairness and the ultimate advantage of preferring direct information from the respective constituted authorities, of requiring advice from rival institutions upon doubtful measures, and of regarding with jealousy the private communications of interested individuals. It is, however, reported that you are, at this time, beset upon the subject of introducing an ordeal for licensing man-midwives, by certain members of the London College of Surgeons, and that you are urged by popular men (whose wisdom and disinterestedness may be questioned) to favour their scheme with your powerful influence.

As the prevalent vice of avarice may have some share in this professional movement, it is fit that you and the public should be acquainted with the probably concealed effects of granting the solicited privileges; and for the reasons already given, I am induced to address you through the press.

Man-midwifery has only been practised in England during the last hundred years, and it was introduced as a French fashion. From the beginning it has been strongly opposed on the score of its indecency, by many distinguished and scientific medical men, and also, because the birth of mankind appeared to them to be a purely natural process, so wisely ordered, that it very rarely demands any other aid than experienced mothers can safely give. Even so late as the time of the illustrious mother of his present Majesty, that exemplary Queen was personally attended by good Mrs. Draper, without difficulties or misadventures; whereas the contrary result, under male management, in the fatal affair of the Princess Charlotte and her infant, will be long remembered.

If it should be asked why so many professional men addict themselves to a degrading vocation, it may be answered, that the practice of man-midwifery leads to unlimited power in every family, and thence to lucrative ends. Women, naturally timid, and ignorant of their own structure, are peculiarly exposed, during the most important office of their existence, to the persuasions or menaces of more knowing persons, and they are thence easily made to believe, that the natural and wholesome delays and pains of child-bed are within the control of medical or surgical art,—an assumption which is too generally acted upon, and with unvarying evil consequences; because it is a violation of the ways of nature. Man-midwives have continually alleged, that ignorant women practitioners commit many fatal mistakes, and now they present similar objections against unlicensed men. If, as I believe, the safeguards of child-birth are amply provided by nature, and that not one instance in a thousand calls for any other help beyond what any moderately experienced woman can safely give, why are we to license adventurers, who may seek notoriety by desperate acts, often involving manslaughter—operative acts, the moral propriety of which is very doubtful, and the time and the methods for performing them, still subjects for rancorous disputes? But the present affair is not respecting the utility of man-midwives, but the impropriety of empowering any special corporate medical body to coerce the rest; to further impede female-midwives in a becoming duty, and to deprive delicate women of that great resource of self-respect. Already the prevalence of man-midwifery has driven country surgeons and apothecaries to adopt this humiliating office, and the number of women practitioners has been thence so reduced, that paupers are in many places delivered by apprentice boys under 16 years of age. The Royal College of Physicians in London, who rank the highest for learning and for decorum, have lately rescinded their admission of licentiates in midwifery, whether from considering the practice as derogatory to a physician, or as an overweening privilege toward females and children, is not avowed; but it seems that no London physician educated at Oxford or Cambridge, has yet condescended to be a man-midwife. The Royal Colleges of Surgeons in London, in Dublin, and in Edinburgh, have likewise hitherto renounced every connexion with man-midwifery.

The teachers of midwifery are indiscriminately doctors and surgeons, but at this moment the majority of lecturers and superintendents of lying-in charities are physicians, while a multitude of legally appointed sub-physicians (styled apothecaries) are equally entitled, with the other classes of the faculty, to establish tribunals for examining and licensing candidates for man-midwifery, if they could deem it expedient. Finally, it may be noted, that the different classes of man-midwives have never yet agreed among themselves to adopt a common ordeal for certifying the qualifications of their calling, and you may be assured, Sir, that many worldly interests will rage against the establishment of any monopoly of this kind in any single institution, because man-midwifery is the covert way to medical fortunes. If, however, the greediness of a few individuals should expose this subject to free discussion, and the judgment of married men and modest women should be copiously awakened, perhaps the general custom of employing women may be again resorted to, and their competent instruction publicly enforced.

It is said, that our changeable neighbours at Paris are already tired of their fashionable freak, and when our countrywomen reflect, that not one in ten thousand of their sex throughout the globe allow of the presence of a man during the rites of child-bed, they may acquire courage, and unite their efforts to replace the routine of midwifery among themselves. I will not offend you and the public by any observations upon the outrageous stories collected on this occasion, to prove the violent and fatal injuries committed by unlicensed man-midwives, because I think the privilege sought for would increase those evils.

With the greatest respect,
I have the honour to be,
Your very obedient servant,
ANTHONY CARLISLE.

Langham-place, Feb. 19.

NOTE:—The above letter, which became notorious, was printed on page 701 of THE LANCET. The following appears at the bottom of page 712:

"THE Letter of Sir ANTHONY CARLISLE, at page 701, is a curiosity, and just the testaceous sort of thing one would expect from the pen of an OYSTER."[1]

[1] Sir Anthony Carlisle was dubbed "Oyster" because during the delivery of his Hunterian Oration before the Royal College of Surgeons on Feb. 14th, 1826, he produced inappropriately a large oyster and dissected it and descanted on it with the "most obstinate and tedious minuteness." "Sir A's OYSTER so completely *sickened* his auditory, that their frequent ejections of it, by *coughing* and *gulping*, hurried him to an abrupt conclusion." (Vide THE LANCET, Feb. 18th, 1826.)

A CENTENARIAN.—At a recent meeting of the Long Ashton (Somerset) board of guardians it was decided to grant extra relief to Mrs. Honor Coleman who attained the age of 104 years on Feb. 22nd.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER III.[1]

THE FIGURES OF THE MEDICAL PROFESSION AND THE CHANCES OF SUCCESS.

The Ratio of Medical Men to Population.—The Figures in Austria-Hungary, France, and Germany.—The Average of Success.—Sir James Paget's Investigation.—A Supplementary Investigation.—The Fallacy of Figures.

THE numerical ratio of employed to employer is one of the first things to look at in an attempt to estimate the material or financial position of the members of any section of the community. There is particular reason to do this in respect of the medical profession because it is alleged that many of the grievances which medical men can show to exist in their professional life are due to the down-grade tendencies of competition. Of course, the services of an overcrowded profession will be obtained more cheaply by the public, but it will not do to assume without inquiry that the medical profession is overcrowded, if only because a *general* excuse for *many and particular* ills should never be accepted without rigorous test. If it once becomes a matter of assumption that unprofessional practices must occur, that low remuneration must be received, and that humiliating contracts must be entered into because of the demoralising influence of overcrowding, the desire to remedy abuses will be killed by a fatalistic tendency to put up with a condition of things which is supposed to be due to some unalterable law of supply and demand. The figures do not bear out the statement so frequently made that the profession of medicine in this country is grossly overcrowded.

The first of the tables which follows gives a numerical analysis of the members of the medical profession taken from back numbers of the Medical Directory. I have given the figures for the last six years consecutively and have then added those for 1861, 1871, 1881, and 1891, so that the respective figures in these columns may be compared with the population of the United Kingdom according to the decennial census for those years.

The second table gives the population of England (including Wales), Ireland, Scotland, and the Islands for the years 1861, 1871, 1881, 1891, and 1901.

Taking as a guide the decennial increase of England and Scotland and the decennial decrease of Ireland it is probable that for the present purposes 42,750,000 represents sufficiently nearly the population of Great Britain and Ireland. We therefore see that in 1861 there was one registered medical man to 1271 inhabitants; in 1871 there was one medical man to 1370 inhabitants; in 1881 there was one medical man to 1558 inhabitants—the population having taken an upward leap; in 1891 there was one medical man to 1283 inhabitants; in 1901 there was one medical man to 1144 inhabitants; and in 1904 there was one medical man to 1133 inhabitants. These figures must further be corrected to the advantage of the medical man by subtracting the registered practitioners resident abroad and a certain number of the medical men holding commissions in one of the three services. By making these necessary allowances it becomes clear that the ratio of medical men to the public to-day is really much the same as it was in 1861 or 1871. May it not be taken for granted that a numerical ratio which has held good, with but one considerable variation, for 40 years or more has something inherently right about it?

That the members of the medical profession in England (including Wales), Scotland, and Ireland are divided in such a way as to create a plethora in one place and a dearth in another is a different matter altogether, though here we are at an advantage over other countries. In Austria-Hungary, for example, where 18,000 medical men minister to the needs of 47,000,000 people, it will be seen that the ratio of medical men to population is only half

[1] Chapters I. and II. were published in THE LANCET of Feb. 18th (p. 447) and Feb. 25th (p. 517), 1905, respectively.
[2] The proprietors of the Medical Directory, Messrs. J. and A. Churchill, kindly furnished the information for compiling these tables.

that which obtains in Great Britain and Ireland. But, as a matter of fact, there are many districts in the provinces of the dual empire with no medical men at all, all the practitioners being crowded into the cities and watering places. The 18,000 medical men do not serve a population of more than 25,000,000 or so and the real proportion does not differ much from that found among ourselves. In France the figures are a little different, the same number of medical men approximately (18,871) having the care of a population of 39,000,000. But in France also there are vast tracts of country where medical men are very few, though homogeneity of race and language prevents the complete isolation of districts which prevails in Austria-Hungary. In Germany there is one medical man to 1934 of the population, the great towns being especially over-provided with physicians and surgeons. In Berlin the proportion of practitioners to population is 1 to 766, in Munich it is 1 to 608. But in some of the outlying provinces there are no medical men at all. Take the province of Gumbinnen, for instance, a district in Eastern Prussia, near the Russian frontier. Here the proportion of medical men to population is 1 in 4100. It is such inequalities in distribution that produce the problem of overcrowding in certain places, and in England and Scotland and Ireland these inequalities are less marked than in Germany, France, and Austria. Of course, our capital towns, our best known watering places, and the sites of our medical schools attract many as family practitioners, as consultants, or as teachers, but the general social and geographical conditions with us conduce to a more or less even distribution of medical service. The contention that the serious overcrowding of the medical profession makes it impossible to remove many of the grievances which are certainly present in the medical life cannot be sustained. Here and there the stress of competition tells, and tells forcibly, but on the whole it has been exaggerated.

We come now to another consideration showing the medical profession to be not such an arduous and wretched life as it has been described sometimes by doleful writers. In 1869 Sir James Paget undertook, with the assistance of a colleague at St. Bartholomew's Hospital, an investigation into the chances of the medical student as shown by his subsequent career. The investigation resulted in the publication of figures showing that a medical student had at least as good a chance of worldly success as a lad embarking in any other career. Sir James Paget followed up the lives of 1000 medical students who had joined the medical school of St. Bartholomew's Hospital with the following result:[3] 23 met with distinguished success, 66 met with considerable success, 507 met with fair success, 124 met with very limited success, 56 failed, 96 discontinued medical studies while in pupilage, 41 died during pupilage, and 87 died within 12 years of commencing practice.

Sir James Paget defined "distinguished success" as the attainment within 15 years of qualification to a leading position in practice in great cities, to a scientific professorship at a university, to a place on the staff of a large hospital, or to the tenure of some important public office. He ascribed "considerable success" to those who gained high positions in the services, obtained good provincial and country practices, and enjoyed more than ordinary esteem and influence in society. "Fair success" he defined as being in the possession of a practice sufficiently large to maintain a professional man in adequate style, or the tenure of an advancing position in the naval, military, Indian, or colonial services. "Very limited success" he assigned to those who never attained to moderately good practice, but who were able just to maintain themselves by their work either as principals or as assistants. Of the 56 who failed 15 could not pass their examinations, five were convicted of misconduct, ten were dissipated both as students and afterwards, and ten had bad health. The remainder were known to have come to grief without any particular reason being assigned for their misfortune. It will be seen that out of the 1000 students 41 died during pupilage and must be left out of count. Again, the 96 who discontinued their medical studies while in pupilage can hardly be brought into calculation when we are considering the chances of making a livelihood out of the practice of medicine. They cannot be said to have failed in a medical career as they never attained to professional rank. The fact that nearly 10 per cent. of the 1000 students left the profession during their studies is not without significance, as it would seem to imply that the medical profession was not one to be undertaken lightly even in days when examinations were comparatively simple and infrequent, but this is a different matter altogether. A parent when sending his son into the medical profession ought to know that there is a chance of that son never obtaining any qualifications. But this should not be mixed up in his mind with apprehensions as to the future, after qualifications have been obtained. The 41 who died during pupilage, and the 87 who died before they had been in practice 12 years were also debarred by sad fate from obtaining any position in their profession, and they can be left out of calculation for practical purposes. We have then 776 students to consider who actually reached practice, and of these 507, or about 66 per cent., attained to fair success. These are the figures that we must look at when we try to frame our opinion as to the chances that a boy has of becoming a useful, happy, and responsible citizen if he elects a medical career.

The figures that signify success above the average or total want of it are not without their lessons, the number and magnitude of the prizes to be attained being an inducement to join the profession, exactly as the risks of failing utterly at the beginning form drawbacks to a start in the race. The early wastage is a matter of grave importance both to parents and to aspirants to the medical profession and there is every reason to believe that it has increased of late owing to the multiplicity of examinations. Again, the dearth of lucrative appointments and the comparatively small pecuniary gains that accompany distinguished success are matters that must not be disregarded. The successful medical man may attain to a high position and a large fortune, but he does so very rarely, and many men who conform to Sir James Paget's definition of distinguished success live and die without popular favour, their names being unknown to the majority of their fellows, their incomes being small, and their public influence negligible. It stands to reason that a profession where so many of the prizes resemble blanks will not be selected either for themselves or for their children by those who have a keen eye to the material opportunities of life. But if the young medical man sees no high position within his possible grasp comparable to that of the judge or the bishop, if he has not the golden expectations of the man of affairs, still he may have visions of scientific fame, altruistic dreams of serving his generation, and generations to come, immortally well, and such a man would not exchange his hopes for the chances held out by other callings. Alas, that his hopes must, in the nature of things, be so seldom realised, but distinguished success, as gauged by pecuniary standards, can visit but few of the followers of medicine. The owners of oil, the operators in wheat, the directors of fleets and railways may work their monopolies against the public but any advance in medicine is at once placed freely at the public disposal.

But although the money rewards in the medical profession are small, and although the public offices filled by medical men do not appear important to those ambitious for popular authority, the very significant fact appears from Sir James Paget's figures that 66 per cent. of medical men make a fair success in England, Scotland, and Ireland out of the practice of their profession. This seems at once to place the medical profession quite high as a stable means of livelihood. The barrister, the clergyman, the architect, and nowadays the solicitor cannot claim the same for their callings. If an investigation on the lines suggested by Sir James Paget were undertaken into the careers of 1000 divinity or law students, it is certain that no such high average of comparative success could be shown. As, however, nearly a working lifetime has elapsed since Sir James Paget's research into the careers of a group of his numerous pupils at St. Bartholomew's Hospital was made, it might be thought that with the lapse of time and the alteration of conditions the figures would no longer hold good. Bearing this in mind permission was obtained from the dean of one of the best known English hospitals to make a brief investigation into the careers of a group of students who had been entered for education at the medical school of that hospital.

---

[3] St. Bartholomew's Hospital Reports, vol. v., 1869.

The year 1879 was chosen and what happened to the first 250 students who entered after Oct. 1st at that institution was ascertained superficially. The date was selected because the writer joined the school a little later and was able from personal knowledge to remember facts and circumstances in the lives of a large proportion of the men under consideration, some having been his teachers and some his comrades, while, where personal acquaintance failed, it was easy to find a friend who could supply the gaps in the information. Of the 250 students 187 qualified and 63 did not qualify. Of the 63 who did not qualify as medical men two obtained places in the dental register without diplomas and are doing well and two died as students; one is decently successful at the bar, one became a veterinary surgeon and enjoys a high reputation in that profession, one accepted a purely scientific post under Government and is steadily rising in his department, one became an artist, three went on to the stage with no success, two enlisted in the army and both obtained commissions, and one became proprietor of a boarding house. Four of them who gave up the struggle were men of private means to whom the practice of a profession was not necessary as a livelihood. Of the remaining 45, 15 of them never showed the least aptitude for medicine, and among these are classed five or six lads who lived mainly for the sensual pleasures of a life in a great city.

Of the 187 students who qualified nine may be said to have met with distinguished success as defined by Sir James Paget, five of them secured after more or less waiting positions on the medical or surgical staff of their own hospital, and two became teachers at the hospital. Two others are on the staff of large general hospitals in the provinces. 45 have met with considerable success in practice. They hold good appointments, have earned a local position, and are respected and prosperous citizens. 25 hold commissions in the services, 19 in the army and six in the navy. Of these, two have distinguished themselves and have been decorated, one having become head of an important department. Of 56 men in general practice in England, including five who practise dentistry, I have been able to learn that they are living by medical practice in a manner compatible with a professional position; out of nine who are abroad two have been distinctly successful. Five men who obtained qualifications left the medical profession, of whom one is a journalist, one is an actor, one has also been on the stage, and two are men of private means. I know of only six men who came distinctly to grief, of whom two went to prison. 23 men died before they had been qualified 12 years and must be disregarded in making any estimate as to the chance of success by the practice of medicine. Of the rest, about 12 per cent. of the total, I have been unable to learn anything, though their position on the Medical Register would imply that they are still in practice.

The following are the figures which can be compared with Sir James Paget's figures: nine have met with distinguished success; 45 have met with considerable success; 25 have met with fair success in the services (two of these might be included in a higher class); 46 have also met with fair success in practice; five left the profession after qualification; six discontinued medical study as pupils; two died during pupilage; 23 died within 12 years of commencing practice; and six failed entirely. Liberality has been shown in awarding places in the higher classes, but if we add the "considerable" and "fair" successes together we get by the combination a section of 116 men out of 187. That is to say that the figures, like Sir James Paget's figures, though with much less certainty because of their incompleteness and the smaller range of the investigation, go to show that 66 per cent. of qualified medical men from one metropolitan medical school have reason to be satisfied with their professional careers.

Too much stress must not be laid upon the meaning of any of the foregoing figures. That figures, particularly if large deductions are attempted from small data, can be made to prove most things is illustrated in many controversies and it is safer to claim proof for as little as possible through their agency. But the figures can fairly be used as replies to two vague but common assertions: (1) that the medical profession is overcrowded; and (2) that in following the medical life the game is not worth the candle. These two statements have been made so often that they are beginning to receive unquestioned acceptance. As a matter of fact, the medical profession in England, Scotland, and Ireland is not overcrowded so much as badly distributed. There are services where medical men are sorely needed and where they would be found if the conditions were fair; there are large districts where medical work is waiting to be done until proper arrangements have been made by the State for doing it. When the administration of the Poor-law and the sanitary service in the three countries is considered, as well as the warrants of the naval and military services, it will be seen that certain necessary measures of reform would at once create a demand for medical officers. The employment is ready, but as yet no proper provision exists for the employed. This is not the same thing as saying that the medical profession is overcrowded.

Again, the percentage of medical men who attain a good and stable position through professional practice disproves the view that the medical profession as a whole is wrongly paid. But the figures must not be taken to show that there are no grave professional hardships. In both cases they refer to students at first-class London hospitals, students of the class who enter the profession with fine introductions and whose natural sphere of practice presents the maximum of opportunities. It would be possible by selecting students of other schools to obtain somewhat different results, though not results that would contradict the general inference that by comparison with many other callings the medical profession promises much.

(To be continued.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7826 births and 4704 deaths were registered during the week ending Feb. 25th. The annual rate of mortality in these towns, which had been 18·0, 17·4, and 17·3 per 1000 in the three preceding weeks, further declined to 15·7 per 1000 last week. In London the death-rate was 16·0 per 1000, while it averaged 15·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3·7 in Hornsey, 8·2 in King's Norton, 8·3 in Wallasey, 8·5 in Rochdale, 9·3 in Handsworth (Staffs.), 9·9 in Walthamstow, and 10·1 in East Ham; the highest rates were 21·0 in Hanley, 21·4 in Warrington and in Bury, 22·8 in Ipswich, 24·7 in Wigan, 26·3 in Portsmouth, and 29·8 in Stockton-on-Tees. The 4704 deaths in these towns last week included 365 which were referred to the principal infectious diseases, against 368, 401, and 410 in the three preceding weeks; of these 365 deaths, 110 resulted from measles, 102 from whooping-cough, 61 from diphtheria, 38 from scarlet fever, 27 from "fever" (principally enteric), and 27 from diarrhœa, but not any from small-pox. No death from any of the principal infectious diseases was registered last week in Hornsey, Bournemouth, Norwich, Handsworth (Staffs.), King's Norton, Smethwick, Coventry, Wallasey, Warrington, Barrow-in-Furness, York, or Swansea; while they caused the highest death-rates in East Ham, Portsmouth, Southampton, West Bromwich, Nottingham, Middlesbrough, West Hartlepool, and South Shields. The greatest proportional mortality from measles occurred in East Ham, Portsmouth, Southampton, West Bromwich, Leicester, Nottingham, Stockport, Middlesbrough, West Hartlepool, South Shields, and Cardiff; and from whooping-cough in Hastings, Hanley, *Nottingham, Preston, and Hull. The mortality from each* of the other principal infectious diseases showed no marked excess in any of the large towns. No death from small-pox was registered either in London or in any of the 75 other large towns. The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals, which had been 13, nine, and eight on the three preceding Saturdays, had increased again to 15 on Saturday last, Feb. 25th; seven new cases were admitted during the week, against one, one, and three in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 1987, against 2070, 2077, and 2016 at the end of the three preceding weeks; 224 new cases were admitted during the week, against 229, 260, and 241 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 444, 400, and 378 in the three preceding weeks, further declined to 335 last week, but were 13 above the number in the corresponding period of last year. The causes of 62, or 1·3 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Salford, Bradford, Leeds, and in 44 other smaller towns; the largest proportions of uncertified deaths were registered in Ipswich, Birmingham, Grimsby, Liverpool, Warrington, Barrow-in-Furness, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the prin-
of l Scotch towns, which had been 19·9, 18·2, and 18·9
00 in the three preceding weeks, declined again to
23 met with dis during the week ending Feb. 25th, but
success, 507 met in excess of the mean rate during the
success, 56 failed, 76 large English towns. The rates in
in pupilage, 41 diedowns ranged from 13·4 in Paisley
years of commencing pgh to 23·8 in Dundee and 25·9
aths in these towns included 27
Sir James Paget definwhooping-cough, 13 to diarrhœa,
attainment within 15 yea. measles, six to diphtheria, and
position in practice in great not any to small-pox. In
ship at a university, to a place these principal infectious
49, and 52 in the three
or to the tenure of some importas were equal to an annual
"considerable success" to those 0·7 per 1000 above the
in the services, obtained good me diseases in the 76
practices, and enjoyed more thans of whooping-cough,
influence in society. "Fair success" wo preceding weeks,
the possession of a practice sufficiently ch 16 occurred in
in Paisley. The

never attained to moderately good practice, fever," which
able just to maintain themselves by their weding weeks,
h four fatal
principals or as assistants. Of the 56 who faind four of
which had

been six, seven, and four in the three preceding weeks, rose again to seven last week and included four in Glasgow and two in Edinburgh. The fatal cases of diphtheria, which had been three in each of the two preceding weeks, increased last week to six, of which three were registered in Edinburgh and two in Dundee. The two fatal cases of scarlet fever occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 146, 130, and 119 in the three preceding weeks, further declined last week to 116 and were 49 below the number in the corresponding period of last year. The causes of 21, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death-rate in Dublin, which had been 24·2, 25·2, and 23·5 per 1000 in the three preceding weeks, rose again to 25·5 per 1000 during the week ending Feb. 25th. During the past four weeks the death-rate has averaged 24·6 per 1000, the rates during the same period being 17·0 in London and 18·1 in Edinburgh. The 185 deaths of persons belonging to Dublin registered during the week under notice were 14 in excess of the number in the preceding *week and included five which were referred to the* principal infectious diseases, against nine, seven, and eight in the three preceding weeks; of these, three resulted from measles, one from whooping-cough, and one from diarrhœa, but not any from small-pox, scarlet fever, diphtheria, or "fever." These five deaths were equal to an annual rate of 0·7 per 1000, the death-rates last week from the principal infectious diseases being 1·0 in London and 1·7 in Edinburgh. The three deaths from measles, were slightly in excess of the number in the preceding week; the mortality from whooping cough and from diarrhœa corresponded in each case with that recorded in the preceding week. The 185 deaths in Dublin last week included 43 of children under one year of age and 43 of persons aged 60 years and upwards; the deaths of infants and of elderly persons were 16 and four respectively in excess of the numbers in the preceding week. One inquest case and two deaths from violence were recorded; and 61, or nearly a third, of the deaths occurred in public institutions. The causes of 13, or more than 7 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES

Royal Navy Medical Service

The undermentioned Staff Surgeons have been promoted to the rank of Fleet Surgeon in His Majesty's Fleet: Lawrence Bidwell, Edward Henry Hodnet de Courtmacsherry, Walter James Bearblock, William Hackett, Charles Geekie Matthew, Thomas Austen, and Joseph Chambers.

The following appointments are notified:—Fleet Surgeons: H. F. Iliewicz to the *Cressy* on commissioning with nucleus crew; R. Miller to Bermuda Hospital and Dockyard on reduction of establishment; G. E. Kennedy to the *Royal Oak*, on recommissioning; and O. Bradley to the *Cæsar* on commissioning. Staff Surgeons: G. Ley to the *President*, additional, to assist in the survey of stores at Yarmouth Hospital, temporary. Surgeons: H. R. Gardner to the *Cæsar* on commissioning; F. C. B. Gittings to the *Wildfire* for Sheerness Dockyard; E. S. Reid to the *Hannibal*; and D. V. Lowndes to Bermuda Hospital and Dockyard on reduction of establishments.

Royal Army Medical Corps.

Lieutenant-Colonel G. F. Gubbin, Major A. Hosie, Major E. Eckersley, and Major C. W. H. Whitestone are appointed to the Eastern Command. Major W. W. O. Beveridge, D.S.O., from Cape Colony, is appointed to the London District for duty. Surgeon-General W. H. Macnamara, C.B., C.M.G., Principal Medical Officer, Aldershot Army Corps, proceeds on leave of absence, with permission to travel in France and Switzerland. During his absence his duties are being performed by Colonel G. W. Robinson, commanding the Depôt and Training School, Royal Army Medical Corps.

Indian Medical Service.

Lieutenant-Colonel H. K. McKay, C.I.E. *(Bengal)*, has been appointed Inspector-General of Civil Hospitals and

---

[3] St. Bartholomew's Hospital Reports, vol. v., 18

Sanitary Commissioner, Burmah, vice Lieutenant-Colonel S. Little. Major C. H. Bedford is posted to the Finance Department.

ARMY REFORM.

In the debate on the Address the question of army reform was bound to occupy a prominent position and such has been the case. Mr. Arnold-Forster's scheme was severely criticised in the House of Commons but the Minister of War nevertheless defended the position he had taken up with great ability and no semblance of having any misgiving in his mind. With all the characteristic enthusiasm that he has hitherto shown in defence of his scheme he traversed with a direct negative all the assertions that had been advanced against it. The debate was nevertheless disappointing owing to its discursive nature and to the fact that it embraced too many subjects on almost all of which further and fuller information is still needed. The whole subject will be again taken up when the Army Estimates are considered and it is to be hoped that Mr. Arnold-Forster will then be able to give fuller and more satisfactory assurances than he has hitherto done—especially in regard to the position which army hygiene and our army medical system and service are to occupy in the wars of the future. Meanwhile we may refer to what the War Minister said in the course of his speech in which he very fairly pleaded for further time for the carrying out and development of his reforms. As regards the construction of barracks, which crucially affects the welfare of the soldier, he said: "We have put the business of barrack building under the supervision of an experienced civilian who has had the control of the erection of such buildings as the Rowton Houses in London and Birmingham. The experience he has had well qualifies him for devising barrack accommodation for the comfort and welfare of the soldier. The hon. Member for Ilkeston asked whether we have made any progress with the medical service. When I tell him that not only have careful observers made themselves acquainted with developments during the Russo-Japanese war, but we have at last commenced the erection of the medical college in which he is interested, I do not think there is altogether a bad record," and Mr. Arnold-Forster subsequently added that the Royal Army Medical Corps had been increased by 462 officers and 1210 men. In view of all that has taken place in the Russo-Japanese war the nation and the medical profession will look forward to the medical reforms which Mr. Arnold-Forster has to propose with anxious interest.

SOLDIERING IN SCHOOLS.

The subject of the military training of the youth of this country was recently brought forward by the Earl of Meath in the House of Lords where it gave rise to a brief but interesting discussion which led, however, to no practical result. All who took part in the debate were apparently agreed about some sort of military training being essential to secure the physical fitness of the rising generation and for developing among them a spirit of patriotism and sense of discipline and national duty. But while measures taken by the Education Department for improving voluntary drill had been attended with satisfactory results, the Earl of Donoughmore urged that there was plenty of evidence forthcoming that offers of the War Office to supply instructors on a compulsory basis would not be favourably met by the headmasters of secondary schools. In the present circumstances and as a result of their experience, the War Office was not encouraged to attempt any compulsory drilling in the schools.

PHYSIQUE IN THE ARMY.

The *Standard* of Feb. 28th states that "important appointments not previously contemplated have been made in connexion with the new organisation of army commands in respect of recruiting. The War Office have announced that a medical inspector of recruits is to be stationed at the headquarters of each command charged with the responsibility of securing recruits for the army of the requisite physique, and his duties are to extend to the militia, yeomanry, and volunteers. He is to visit the regimental depôts of the regular forces and militia, inspect the recruits, and superintend their physical training, and he is also to attend at the drill halls of volunteer corps and examine the recruits as to their stature and chest measurement, and report as to those for whom the capitation grant should be withheld. The announcement of the appointments for these duties have been favourably received in military circles. Lieutenant-Colonel Reid, R.A.M.C., has been appointed to the southern [illegible]mmand."

THE WAR IN THE FAR EAST.

The recent publication of the decision of the North Sea Commission, added to the reports regarding the internal condition of Russia and the rumours about peace, has tended still further to divert public attention from what is going on at the actual seat of war in Manchuria. Summarily stated the news from there amounts to this: that the Japanese are making attacks on the mountain passes and are pressing forward and threatening the Russian extreme left which is giving way before the Japanese advance from the south-east. It is noteworthy that at the present time nearly all the military news appears to be coming from Russian sources; the Japanese do not, as a rule, report any movements until they have something decisive to declare officially. As regards the medical events of the war, on the other hand, the Russian authorities are very reticent. We know officially little or nothing of the health conditions of the Russian forces in the field, but it is certain that their losses, and especially those from disease, have been very great and in striking contrast with the highly favourable statistical results which have been recorded of General Oku's force. As far as can be gathered from independent sources the Russian forces in the field have greatly suffered from preventable causes of disease and from lack of timely foresight and supplies as well as from overcrowded hospitals arising from the overwhelming number of sick and wounded. Added to these causes the nervous depression arising from repeated defeat is also a factor which must not be forgotten. A beaten army is almost invariably a sickly one—a prey to any prevailing diseases. The weather until quite recently has been extremely cold but the Japanese state that their troops have not suffered from frost-bite.

Whilst the outrage by a Russian general on a medical man is still the subject of columns of discussion in the Russian press the *Vostotchnoe Obosrenie* publishes an order by General Nadaroff, setting forth that on the night of Nov. 24th last three medical men in Kharbin hailed a cab but the coachman would not move. The dispute brought about a crowd of people and policemen who took the medical men to the police-station where they passed the night in a dirty cell amongst a degraded assortment of fellow prisoners. No attention was paid to their request to see the officer in charge of the [illegible] to him. They [illegible] into the cell. [illegible] t of the defective organisation in the local police force and notifies the dismissal of the chief officer nominally in charge of the station for not being within call. The sergeant has been sentenced to imprisonment and dismissal, the coachman has been sent away from Kharbin till the end of the war, the police who struck the medical men have been imprisoned and dismissed, and many more minor degrees of guilt in connexion with the occurrence have been visited with proportionate degrees of punishment." The order concludes with a special request to General Chorvata, who directs the Eastern Chinese railway, to make such disorderly proceedings impossible in future.

The officers of the Royal Military College, past and present, have presented as a farewell gift to Lieutenant-Colonel Alfred F. S. Clarke, R.A.M.C., on his leaving Sandhurst after 22 years' service as surgeon of the College, a silver salver with suitable inscription and an opal and diamond ring for Mrs. Clarke.

ROYAL INTEREST IN FOOTBALL.—Amidst considerable [illegible] King and the Prince of Wales we[illegible] ice football match on Saturday [illegible] the match interested spectators. [illegible] Officer Stirland met with [illegible] the field by Mr. F. G. Lloyd [illegible] ies from the King and the Prince [illegible] patient whose injuries were not of a serious character.

UNIVERSITY OF CAMBRIDGE.—Mr. A. W. Hill, King's College, has [illegible] university lecturer in Botany.—Mr. F. F. [illegible] ge, has been appointed an exami[illegible] —Dr. Joseph Griffiths, M.A., of King's College, has been approved for the degree of Master of Surgery.—Mr. E. H. Hankin, M.A., St. John's College, bacteriologist to the North-West Provinces and Oudh, has been approved for the degree of Doctor of Science.

Correspondence.

"Audi alteram partem."

THE INDIAN MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the leading article in THE LANCET of Feb. 18th, p. 441, on the position of the profession in India. The position is undoubtedly a difficult one both for the Indian Medical Service and for the graduates and licentiates of the universities and colleges in India. On the one hand the Indian Medical Service finds that the conditions which led in former days to lucrative consulting practices and to opportunities for making great reputations are being considerably curtailed and threaten in time almost to disappear. Many of the civil appointments in the mofussal or country districts which at one time were moderately lucrative are not so now and even the prize appointments in Calcutta and other large towns in India, which were held by such men as Fayrer, Guyer Hunter, Moore, McLeod, Freyer, Crombie, and a long line of distinguished men, are shorn of much of their value. As years go on matters will become worse in this respect because the more thoroughly the students are taught the less need will there be to call in the services of Europeans, while the chances of large fees from wealthy patients grateful for extraordinary services rendered are now forbidden, and very unfairly, I think, by a paternal Government. It is not surprising that in such circumstances medical officers are jealous of the privileges that remain to them and the time is fast approaching when I think, if the service is to be a contented one, a higher scale of salaries will have to be provided for its officers.

On the other hand, there are the ever-increasing number of qualified men, Indian and Eurasian, coming annually into the field and who are naturally employed by their own people. But this is not sufficient for many of the more talented and ambitious. They see the doors of the higher services of Government closed to them and this produces among them bitter discontent. No graduate of the Indian universities can hope to rise in Government service unless he first comes to England and then, after having undergone a course of study in an English medical school, competes with the young Britishers who are desirous of entering the Indian Medical Service. We may imagine what this means if we reverse the arrangement and insist on English students visiting India and undergoing a course there before being permitted to enter the competitive examination for the Indian Medical Service with Indians and Eurasians in their own country. I believe the regulation, however hard it may appear to be, is nevertheless a wise one and was conceived with the highest purpose in view. It is necessary that the young medical men entering the Indian Medical Service, which is primarily a military one and only secondarily a civil service for India, shall be well acquainted with English customs and shall be familiar with western civilisation. But while holding this view it is impossible to ignore the existence of the discontent engendered by the absence of an outlet for legitimate ambitions and I feel convinced that it would be wise in every sense to find a remedy. I was fully conversant with the position of affairs when I was editor of the *Indian Medical Gazette* and it was partly to meet this aspect of the case and to provide such an outlet for distinguished native graduates and open to them an honourable and proud position in Government service I proposed in 1894 that a public health service should be formed in India. This proposal met with the hearty support of most of the prominent men of the Indian Medical Service and was received with enthusiasm by the Indian graduates. The necessity of this service in the interests of the public health of India I need not dwell upon here. It is fully set out in my address on Preventive Work in the Tropics published in THE LANCET of August 27th, 1904, p. 577, in which it is shown that until India possesses such a service she will be the prey, as she is now, to epidemics of great magnitude.

Not belonging to the Indian Medical Service but by my position in India coming into intimate relationship with its officers, many of whom I count among my friends, and at the same time being friendly with the most influential native medical men, I have had exceptional opportunities of forming an unbiased opinion on the subject in question and it is because a remedy will require to be found to ameliorate a state of things which is becoming more acute every year that I venture to recommend that the Government of India should lose no time in carrying out the scheme suggested.

I am, Sirs, yours faithfully,
W. J. SIMPSON, M.D. Aberd.
King's College, Feb. 22nd, 1905.

THE UNIVERSITY OF LONDON AND MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—Dr. Fowler's letter in the *Times* of Feb. 22nd would lead his readers to think that the question of centralisation of the medical schools is unanimously approved by all London medical teachers. This is far from the case. The larger number of the teachers of the preliminary medical sciences were not placed upon the Faculty of Medicine by the University Commissioners and had no voice in the matter when the resolution in favour of centralisation was passed. They were afterwards invited to consider the method of their own abolition. Many thoughtful men among the teachers have grave doubts upon this scheme of centralisation and consider that an alternative and far simpler plan has much to recommend it—to wit, that some of the smaller and more contiguous schools should fuse with others, as they will do under the struggle for existence, while the University of London should endeavour to raise funds to support the larger and most efficient schools by grants in aid. At the same time the University should carry out its real high function of promoting research and higher education by seeking to endow research laboratories such as the physiological laboratory already established in the University by the energy of Dr. Waller and the other London physiologists. Such laboratories would complete the work of the constituent colleges, train and coördinate the teachers.

The members of the centralisation committee suggest that the falling off in number of the medical students in London is due to the inefficiency of teaching and of lack of equipment on the scientific side of the medical schools. Charges of inefficiency might with greater justice be brought against eminent consultants who, having to divide their energies between enormous private practices, hospital practice, and teaching, not infrequently fail to keep in touch with the rapid advances of medical research. The greater decrease in the number of medical students in London has, however, nothing to do with the teaching. It has resulted from the establishment of local universities, whereby students who formerly had to seek London can now live at home and carry out their education at Liverpool, Manchester, Cardiff, or Birmingham, and their parents are saved the expenses and risks of their lodging in London. No centralisation scheme will attract back these students. Great laboratories, high salaries, expensive equipments, and professors with well advertised names neither lead to more research nor to more efficient teaching. A plain room, rubber tubing, glass and wire, and the man may make a Faraday. Medical students require the individual attention and personal influence of their teachers as exerted in small classes and the *esprit de corps* of a hospital; they would not benefit by being herded into vast central lecture halls.

The medical research work published year by year from the laboratories of the London hospitals exceeds in value and amount that put forth by any of the universities of this country, and yet those in favour of centralisation constantly speak of the teachers and laboratories as inefficient. That the teachers are ill paid is true enough, but that has not prevented many men of marked ability and of scholarly tastes from enthusiastically following their science with great advantage both to their students and to the progress of medicine. To many of us it seems unwise to dissociate the preliminary sciences from the hospitals because we recognise that practical medicine is with astonishing rapidity becoming every day more and more a matter of laboratory inquiry and less of clinical experience. The biologist, physical chemist, chemist and physiologist are constantly required to aid the inquiries of the pathologist in the elucidation of disease, and it would be a great loss to hospital patients and patients at large—a loss rapidly becoming ever greater—to remove these scientific *confrères* from daily contact with the clinicians and pathologists. Not only these teachers but the students require continually to imbibe the principles of chemical and physiological science and for the student this is especially needful when in his last years of study he applies his science to disease. I understand that in Sweden the opinion is now freely expressed that the bedside study of disease should come first and the scientific training later in the curriculum; that the empirical study of disease should excite the student to unravel by science both the cause and the cure. There is much to be said for this view.

The vastness of the London area from which medical students come precludes the possibility of one central institute from considerations of time and space. University College and King's College show every sign of intending to remain institutes for the teaching of the preliminary medical subjects, and there is much to be said for the retention of both these and those other schools which have shown by their energy and progress that they are efficient. These schools are conveniently placed north, south, east, and west, and have slowly been evolved to meet the needs of London. Let us improve and not destroy their evolution. If the friends of the medical schools and the University could raise between them enough to contribute £2000 a year to each efficient school to complete its maintenance the whole question would be solved and at a far less expense than the building and endowing of a new central institute.

I am, Sirs, yours faithfully,
LEONARD HILL, M.B. Lond., F.R.S.,
Lecturer on Physiology, London Hospital Medical College;
Examiner to the University of Oxford, Royal College of Surgeons, &c.
The London Hospital Medical College, Feb. 27th, 1905.

SCHOOL GREEK IN SOME OF ITS NATIONAL ASPECTS AND THE *VIA MEDIA*.

To the Editors of THE LANCET.

SIRS,—Lay opinion is not competent to judge of the technical merits of the question now submitted to its vote at Cambridge or of the details of the school reform which seems to be unavoidable; but it can perceive sufficient proof in the uncompromising division between the experts in school and university education that this cause in which national interests are involved is not ripe for sentence but is ripe for adequate investigation. Not less significant is the unanimity with which the experts agree: (1) that the value of Greek for the highest culture is unsurpassed; (2) that the effect of the proposals now made under the names of science, which is not excluded but [illegible] of the University, the tr[illegible] the custodian of lights ne[illegible] uproot it finally out of our [illegible] and spoliation of not the [illegible] intellectual *élite*;' and (3) that the excuse offered to the nation for these extremities is the failure of our present methods to cope with this difficult language without an unwarrantable waste of time The normal inferences which arise from these admissions must speak for themselves.

Hitherto the only profession practically familiar with the workings of the mind and its mechanisms has had no voice in matters of education. If only its experience were to be utilised, could we not command sufficient ingenuity and practical sense, even without looking to the other side of the Atlantic, for a redistribution of school subjects and for a simplification of the study of classics and also of the modern languages, avoiding any gratuitous waste in teaching the latter on the least practical plan, and securing easier and better Greek? The cause of school Greek is linked with that of the reasoned study of languages which must soon take its place among the indispensables for an English university education and to which our race stands specially committed as to a first duty of empire. Philology, the most ancient and also the most modern of the sciences, is itself a higher branch of physiology. It is the soul of our present Renaissance in modern languages and literature and of that *universalism* which is the prominent feature of our age though we are served by the indispensable machinery of *specialism*. Philology now leans upon Greek quite as much as it did at the first Renaissance and the nation and science itself are therefore pledged to place the tuition of Greek as well as of the modern languages upon truly practical lines.

National interests of a different order are served by the popular demand and by the growing facilities for rapid methods of fluency in modern languages, a tardy repentance for the ruinous policy of preferring always the easiest task under the motto "This is a free country." The revival of that policy *ad usum scholarum* would be an anachronism. The safeguarding of the highest educational standards is also claimed in behalf of the great profession of medicine, the interests of which are not indifferent to the State. Hitherto the least favoured, but not the least needed, it is the only profession which, drawing no subventions, contributes a large revenue in the value of the lives which it saves year by year. Its usefulness to the nation must grow in proportion to its influence and the measure of its influence must always be the degree of its culture. As its work is the highest, so should its culture be; and Greek happens to be inseparable from the highest medical education, for in medicine Greek is not a "dead" but a living language. *E pur si muove.* It lives and continues unceasingly its additions to the vocabulary of Hippocrates. Throughout the world its old words and the new are the current language of the profession, though too often their origin is hardly suspected by those who utter [illegible] than a little more [illegible] icient reason why [illegible] he ancient univer- [illegible] as well as of the profession, ever continue to require an undiminished literary and philological training. As to science, some *via media* should be discoverable to satisfy the aspirations of our "moderns" for Cambridge opportunities and degrees without entailing upon the *alma mater* any lapse of dignity or of trust.

In conclusion, our national advantage lies in the expansion of higher culture no less than of science. To science itself better Greek and more philology would be a positive gain. The popular cry for modern languages is the strongest argument in proof of the increasing importance of philology and therefore of Greek in the range of our higher education and is an indirect demand for their cultivation. We seem to have strayed and to have lost our compass but there are landmarks as bold as the Pyramids to help us to find safety in some middle course and to guide us towards a policy of reconstruction rather than of destruction.

I am, Sirs, yours faithfully,
WILLIAM EWART, M.D. Cantab.
The Athenæum, Feb 21st, 1905.

THE SALE OF PATENT MEDICINES ON THE CONTINENT.

To the Editors of THE LANCET.

SIRS,—I shall feel extremely grateful if any of your readers can give me any information with regard to the regulations that are made in continental countries respecting the sale of patent or proprietary medicines. I may add that as far as regards Italy, France, and Germany I have in my possession official information. It is with regard to Russia, Norway and Sweden, and Belgium that I desire some information.

I am, Sirs, yours faithfully,
T. GARRETT HORDER.
32, Windsor place, Cardiff, Feb. 23rd, 1905.

MEDICAL TEACHING IN THE METROPOLIS.

To the Editors of THE LANCET.

SIRS,—My reasons for saying that clinical medicine is ill-taught at the London medical schools are: first, my own observation; secondly, the testimony of others, and among them one who is in a unique position to give a just and disinterested opinion on the matter; and, thirdly, the fact that students from some of the schools are wont to seek elsewhere the teaching they cannot find at their *alma mater*.

I need hardly say that my letter had reference to the London schools generally, not to any school in particular. It would be a piece of impertinence on my part to institute comparisons between individual schools, but in view of Dr. Frederick Taylor's letter, and in justice to the medical school of which he is so distinguished a member, I feel I ought to say that if clinical medicine were as well taught in all the other schools as it is at Guy's (and at least one other) my letter would not have been written. It is just because at Guy's "no assistant physician during the last 40 years has been elected to the staff who has not had experience in teaching and whose capacity to teach has not been taken into consideration as a factor in his election" that this school maintains its high level of efficiency. It is gratifying to know that the school which has produced such a brilliant array of clinicians as Bright, Addison, Gull, Wilks, Pavy, and Moxon—to mention but a few of the long list—has escaped the blight of apathy which seems to have fallen on not a few others.

Dr. Nestor Tirard thinks it probable that at some of the schools medicine is better taught than surgery. This may be so; my contention had reference not to particular schools but to the schools generally. Dr. Tirard contends that the men connected with the non-teaching hospitals in London have all had the opportunity of showing their merits and their teaching powers. In my last letter I submitted that such was not the case. Nor must it be forgotten that many of these men received their education outside the metropolis. In regard to the mystifying quotations supplied by "A Student of 'Boz'" I fear I miss their application. Doubtless they contain some subtle implication but I cannot fathom it. In any case it is not easy to see what the somewhat incoherent utterances of dear old Captain Cuttle and his friend J. B. have to do with twentieth century clinical teaching in London. Much to the point are the practical suggestions of "R. C. H."

May I say, in conclusion, Sirs, that I am well aware that my letter was not of a kind likely to be acclaimed with enthusiasm by the powers that be. I shall be content if it gives food for reflection. "Those who say they have no sin deceive themselves" is no mere empty formula, but a truth pregnant with great issues, as many an individual and many a nation have learnt to their cost. Confession, at least to self if not to others, is a necessary prelude to reform. Let the fact freely and honestly be acknowledged and faced that there is room—great room—for improvement in the teaching of clinical medicine here in London and improvement will follow as a matter of course.

I am, Sirs, yours faithfully,

Wimpole-street, W., Feb. 26th, 1905. HARRY CAMPBELL.

DUODENAL ULCER.

To the Editors of THE LANCET.

SIRS,—I am glad to find from Mr. B. G. A. Moynihan's reply to my letter of Feb. 18th that we are virtually in agreement on the subject of the diagnosis and treatment of duodenal ulcers. The cases which I referred to as having been under my care were all seen by me soon after perforation had taken place and therefore were, as Mr. Moynihan admits, easy to diagnose and simple to treat. I quite agree with him that if peritonitis is present some cleansing must be practised, but even then I am inclined to do as little flushing as possible and to rely rather on one or more drainage-tubes placed low down in the abdomen. Mr. G. R. Turner, in the same issue, seems still to incline to flushing, and I presume therefore that his experience has been confined mainly to the treatment of those ulcers which have perforated some time before coming under his care. If he is advocating the flushing of cases in an early stage before peritonitis has supervened I can only say that I do not agree with him and regard the practice as quite unnecessary, not to say harmful.

I am, Sirs, yours faithfully,

Harley-street, W., Feb. 25th, 1905. W. BRUCE CLARKE.

THE GOUTY DIATHESIS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to make some remarks on Dr. D. Chalmers Watson's article which appeared in THE LANCET of Feb. 11th, p. 347? Carlsbad being the refuge of gouty patients I have had the opportunity of observing almost 400 cases of gout or, respectively, of uric acid diathesis and I think, therefore, that my experience ought to have some bearing on the subject.

Dr. Watson's article, however interesting it may be in itself, does not permit any conclusions to be drawn from it as far as gout is concerned. Dr. Watson fed fowls and rats —i.e., omnivorous animals—on an exclusive meat diet and observed some changes in the thyroid gland. Would he have observed the same changes if the omnivorous animals had been fed on a mixed diet—i.e., on a diet gouty people are in the habit of taking; or would he have observed the same changes had he fed carnivorous animals on an exclusive meat diet?

I am quite certain that the above questions may be replied to in the negative, and as no gouty subject, however fond he may be of meat, is living exclusively on the same Dr. Watson's experiment proves nothing as to gout. In the fairly great number of gouty cases I have had under my care I did not observe in a single case any symptoms which could have related to changes in the thyroid gland; I also found it that some very obstinate cases have never been great consumers of meat, and I had a good few patients under observation who practically abstained from eating meat.

As far as the administration of thyroid extract in gout is concerned I do not think we are entitled to avail ourselves of this drug. I have given it a fair trial in cases of obesity and have found that it is apt, even if very carefully administered, to produce very serious heart symptoms, and how careful must we be as to the heart in cases of gout? I hope to be in a position to publish a report on my cases of gout ere long, on which occasion I shall deal more extensively with the subject. I am, Sirs, yours faithfully,

S. A. ARANY, M.D. (of Carlsbad).

Royal Societies Club, Feb. 13th, 1905.

THE INTRUSION OF THE LAYMAN INTO MEDICAL PRACTICE.

To the Editors of THE LANCET.

SIRS,—In your issue of Feb. 18th there is a note with this title quoted from the title of a letter in *Medical Electrology and Radiology* in which the writer states that a medical man after arranging with him to make a required skiagraph afterwards cancelled the appointment, stating that the patient's brother, also a medical man, had been to our firm and found that he could have the skiagraph taken for a less fee. We have inquired into the circumstances and find that the facts are these.

We were asked by a very old customer simply to take a radiograph of his sister's chest and to do it for him at a specially low fee as expense was an object and being a medical man he looked for special consideration. Naturally we met his wishes, took the radiograph, sent the result to the doctor attending the case, and heard no more about it. There was never a question or suggestion of our making a "diagnosis of a mediastinal tumour."

On a former occasion we had to state that we do not, and never did, undertake the treatment of patients by x rays except at the request, and under the direction, of the medical attendant and in almost every instance the medical attendant of the patient has been present. We undertook this department of business with the hearty concurrence, if not at the actual request, of leading members of the profession and have had their support throughout. We fully understand our position as servants of the profession, heartily endeavouring to assist in all mere mechanical and subsidiary matters and without the slightest desire to encroach on the province of the profession. As a matter of business we find that the profits of radiography are entirely insignificant, though we are aware that ridiculously groundless statements to the contrary have been confidently put forth. If members of the profession prefer to take their patients to professional brethren who practise radiography it is perfectly open to them to do so but several have told us that they object to do this and are glad to avail themselves of our arrangements. Trusting to be able to avoid all reasonable ground of complaint, We are, Sirs, yours faithfully,

ALLEN AND HANBURYS, Ltd.

Bethnal Green, E., Feb. 25th, 1905.

THE INCIPIENT STAGE OF INSANITY.

To the Editors of THE LANCET.

SIRS,—In your issue of Feb. 25th you refer to a short essay of mine on insanity which has recently been published and take exception to some of the statements in it. First of all, you seem to object to my saying that if the signs and symptoms which indicate the approach of insanity were only generally known and the importance of their early detection recognised many persons could be prevented becoming insane. And yet I know from experience that the statement is true. Even during the last two or three years I can call to mind at least five or six cases where an attack of insanity was undoubtedly impending—in two of the cases the patients had actually been previously sent to asylums—and yet by early and energetic treatment they were restored to mental health in a short time and continue so still. This, then, is one of the reasons for the belief that is in me—namely, my own personal experience. Far more weighty, however, than any opinion of mine is that of Dr. T. S. Clouston, the eminent alienist, who in his able and exhaustive treatise on mental diseases thus writes: "If the first signs that betoken danger to the mind's health were observed, the first symptoms of disease noticed and their true significance apprehended, every physician in practice knows that their further onset and progress could often be arrested."

Seeing that I have quoted the above in my essay I think your review is hardly just to me on this point, for surely the [illegible] his unrivalled experience [illegible] holding the belief I do, [illegible] ot confirm it. Why even [illegible] ne would think, partially [illegible] one can hardly see the force of his opening statement—namely, "Among the many *problems connected with psychology one of the most important is the early recognition of symptoms of mental aberration.*" If it *is* important one reason, I suppose, is because if detected early the onset of the disease can at times be prevented.

You next seem to cast a doubt upon my assertion that insane delusions can often be successfully removed and complain that I do not give examples and explain the *modus operandi*. Seeing that the essay does not profess to deal with the *treatment* at all but *only with* the *signs* and *symptoms* of the malady I can hardly be blamed for not including these matters, but in another essay which I have written, and which will be published shortly, I have not only related many successful instances of the kind indicated but have described minutely the exact method of operation. As this second essay will so soon follow the other I think it hardly worth while to go into the matter now, but as the writer of your article seems curious on the point I may say at once that nearly all the methods he mentions are pressed into service, even "argument, entreaty, and cajolery" not being despised when likely to be of the least use in saving a fellow-being from a malady often worse than death itself—namely, insanity.

[illegible] rsons suffering [illegible] insane—I can [illegible] ad and all the [illegible] I have spoken on the subject have always held this view and I can call to mind more than one occasion when I have been politely [illegible] ng the contrary opinion. If, [illegible] alienists generally I should [illegible] lly be pleased at the admis- [illegible] should have allowed all my statements to pass unchallenged and the writer of your review be the first to discover their wholesale fallaciousness.

I am, Sirs, yours faithfully,
C. WILLIAMS.
Liverpool, Feb. 26th, 1905.

COFFEE AND SEWAGE.

To the Editors of THE LANCET.

SIRS,—It is unnecessary to labour the "Coffee and Sewage" question, but I must object to one remark in Dr. R. K. Brown's letter in your issue of Feb. 25th. I gave all my evidence in degrees of the Centigrade thermometer at the request of the magistrate. The bottles containing the coffee, roasted at different temperatures, were distinctly labelled in both scales; they were handed about the court and were in the hands of the sanitary officials. I gave a careful and somewhat long account of the temperatures reached and the changes accompanying each, all in Centigrade degrees. I could not know that the officials were under the impression that 300° *to* 400° Centigrade was reached by the coffee during roasting. In the Fahrenheit scale these become 572° to 752°. I know of no organised vegetable body, such as a coffee berry is, that could be heated to such temperatures, the mean of which is above the melting point of lead and the higher above that of zinc, without destruction.

Coffee is heated to roast not to carbonise it.

I am, Sirs, yours faithfully,
R. J. FRISWELL.
Great Tower street, E.C., Feb. 28th, 1905.

THE QUEEN'S JUBILEE HOSPITAL AND THE MEDICAL STAFF.

To the Editors of THE LANCET.

SIRS,—Referring to certain reports relating to this hospital which have appeared in your paper, I am desired by the board of management to inform you that from the numerous applications received the following gentlemen have been selected to fill the vacancies on the medical staff: George Herschell, M.D. Lond.; George W. F. MacNaughton, M.D., M.R.C.P.; E. Canny-Ryall, F.R.C.S.; F. W. Forbes-Ross, F.R.C.S. Lond.; J. Hutchinson Swanton, M.A., M.D., M.R C.P.; William Lloyd, F.R.C.S.; A. Gordon Wilson, M.D. Lond., F.R.C.S. Eng.; J. H. Pope, M.D., F.R.C.S.; A. H. Payan Dawnay, M.R.C.S., L.R C.P.

I am asked to say that all these gentlemen have accepted their appointments with a full knowledge of the recent facts connected with the hospital.

I am, Sirs, your obedient servant,
G. R. EVERITT, Chairman.
Queen's Jubilee Hospital, S.W., March 1st, 1905.

THE CLERKSHIP OF ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I find there is a widespread rumour to the effect that I was a candidate for the clerkship of St. Bartholomew's Hospital. As the report has been circulated with very circumstantial details I ask the hospitality of your columns to enable me to deny the report. I attach a letter from Mr. W. H. Cross confirming my denial.

I am, Sirs, yours faithfully,
SYDNEY PHILLIPS.
St Thomas's Hospital, Feb 28th, 1905.

⁂ Mr. Phillips incloses a letter from Mr. W. H. Cross who says: "No application from you to be appointed my successor was received here nor, so far as I am aware, was your name mentioned as a probable candidate."—ED. L.

THE RATIONAL TREATMENT OF FRACTURES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 11th, p. 350, Mr. J. Stafford [illegible] ase of fracture of the leg [illegible] Hood's method by means [illegible] tion, light loosely applied splints, and voluntary movement of the adjacent joints, the actual seat of fracture being guarded during this last process. I have carefully read Dr. Hood's brochure and while the plan given for dealing with the stiffness and pain after sprains, &c., and due to adhesions is admirable, and one which I have profited by for many years, it seems to me that the plan sketched for fractures, although abundant for the simple cases which hardly require treatment, is wanting in the very cases which give the practitioner no end of anxiety, [illegible] the law-courts. [illegible] his guide. But [illegible] plan obtains, as among birds and quadrupeds [illegible] While after a time, in spite of muscular movement, a fracture in such animals may be made good, there is much overlapping with consequent shortening and deformity, effacement of the projection taking years to effect. The same may be seen in neglected or fractures difficult to deal with in man. In Dr. Hood's brochure, "The Treatment of Injuries," I can find no reference as to how to deal with the really troublesome cases where there is much overlapping, as in oblique fractures of the bones of the lower extremity (thigh and leg), or where after "reduction" (the necessity for which and for maintenance of correct apposition of the fragments seems to be either ignored or considered of no great importance) there is return of the displacement. May I ask Mr. Mellish if in such cases he would not apply "extension," *ipso facto* implying immobilisation with consequent risk of alleged stiffness and atrophy of muscles? or whether he would allow the malposition to remain for fear of taking means that would interfere with subsequent nutrition of the muscles, in spite of deformity, possible non-union, and the risk of an action for malpraxis? I may state that the last case of severe fracture of the leg bones which I treated carefully by the rubbing method turned out an un-united fracture. Is not the generalisation of so-called rational treatment from the simple cases of clavicle, ribs, Pott's, and Colles's fractures dangerous when applied indiscriminately elsewhere and is there any other rational treatment in the troublesome cases than bone carpentry by cutting down upon, and securing together, the fragments as in Mr. W. A. Lane's plan? I am, Sirs, yours faithfully,

Feb. 20th, 1905. DUBITANS.

THE EPIDEMIC OF TYPHOID FEVER AT LINCOLN.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Lincoln, Feb. 28th.

THE present severe epidemic of typhoid fever at Lincoln gives rise to a number of problems in spite of the apparent simplicity of its origin. Possibly these questions will never be satisfactorily answered, particularly as there is a marked tendency to avoid taking them into consideration. At Lincoln, as at Maidstone, at Hamburg, and many other places, the word "water" is pronounced with solemnity and thereupon it is thought that the question is settled and that nothing more remains to be done. But "water" does not account for the whole situation. Surely if it be acknowledged that the water-supply was contaminated this is but the beginning of the problem. If it sufficed for the water to be contaminated then everyone who drank the water would have the fever and it would prevail in all the streets and districts where it is drunk. Such is not the case and there is as much or more to be learnt by studying the quarters and the class of persons who have escaped as of those who have been stricken down. To stop investigating when once it is proved the water is contaminated is to stop at the very threshold of the problem and to pass unnoticed what may prove the most interesting and, so far as future progress is concerned, the most fruitful indications. Why is it, for instance, that the poorest streets, courts, or alleys of Lincoln have been almost entirely spared? Why did the first cases occur in high-class houses situated on elevated ground and where the domestic drains, subsequently examined, have been found in perfect order?

There are slums in the lowest lying ground, so low, indeed, that they are subject to periodical flooding by the water of the river Witham, and this is the contaminated water. It enters the basements of some of these houses nearly every year. It leaves slimy deposits on the walls of the houses. This is the condemned water in all its foulness, more foul than at the intake for the drinking water-supply and absolutely unfiltered. This dirty water soaks into the walls, it saturates the subsoil, the streets, and the flooring of the houses. The inhabitants are very poor. It is a slum and the poor live and sleep in houses rendered damp by the contaminated and unfiltered water. They cannot touch the walls or floor of their homes without the risk of contaminating their fingers. Their boots are for a great part of the year caked with the mud made by this water. Is it imagined that they wash their hands each time they touch their boots or anything else that is moistened by the water of the much-condemned river Witham? If it be argued that such contact, though very frequent, does not suffice to convey the disease to these people, it must be borne in mind that these tramps, beggars, and hawkers also drank the town water-supply and yet escaped. Further, it may be urged that the water which they drank was more dangerous than usual because they must have taken it from water-pipes near a dead head. That is to say, they live near the end of the pipe where the water can flow no further and, of course, the nearer the end of the pipe the more stagnant the water and therefore the more likely is it to make deposits and to become foul. Consequently these people perhaps ran a greater risk of being contaminated by drinking the town water and they had the supplementary risk of being injuriously affected by the river itself when it flooded their houses. Yet these are the very persons who have suffered the least. Therefore it does not suffice to say that the water was polluted, though I have mentioned but one incident out of many tending to show that other circumstances as well as the water-supply have to be taken into consideration. Besides, is this the first time that the town supply has been polluted? Who would venture to make any such affirmation?

It is said that certainly the river Witham has always been subject to pollution but that no harm has resulted because the water was filtered. On this occasion, however, during the exceptionally cold weather which occurred in November and December, the inhabitants, fearing that their water-pipes would freeze, kept the water running all day and all night. Consequently the rate of water consumption increased about 50 per cent. To meet this increased demand, instead of allowing only 450 gallons to pass per square yard of filtering area, some 750 gallons ran through. Such rapid filtration was not efficacious and it is said that the typhoid bacilli passed through the filters. This probably was the case, though as no examinations were made at the time it will never be known what really did occur. Subsequently samples of water have been taken both before and after filtration. These have been submitted to expert bacteriological examination. The result has not been officially communicated but it is generally understood that the bacilli of typhoid fever were found in the unfiltered water but the result of the examination of the filtered water was doubtful. There is therefore every reason to believe that the water was contaminated with the specific pathogenic germ of typhoid fever. But will anyone in Lincoln answer for it that such an occurrence has never happened before? Also, it may be asked whether the only result of the extra consumption of water due to letting the taps run during the frosty weather was the over-working of the filters. If the estimates given are correct an excess of some 900,000 gallons of water must have flowed per day into the sewers at that time. But that is not all. Such water coming directly from the taps and being unused for domestic purposes, but passing during the freezing weather by surface pipes and drains before it reached the sewer, must have been very cold water. As the sewers, on the other hand, are generally too far below the surface of the streets to be affected by the outdoor temperature they are in winter, comparatively speaking, very warm. Therefore this great and exceptional inrush of very cold water must have produced unusual atmospheric conditions within the sewers. Then, again, there is no natural outlet for the sewage. It all goes to a pumping station and when there is more sewage than the pumps can lift the sewers become water-logged. Thus we find here two different causes working simultaneously to produce such atmospheric disturbances within the sewers as would result in the forcing upwards into the houses and into the street sewer air that differed from the normal conditions in volume and in quality.

So far there have been 745 cases of typhoid fever notified within the city of Lincoln, resulting in 63 deaths. Outside the city boundaries in what might be considered suburban districts there have been 15 notifications and one death at Bracebridge and 28 notifications and one death in the Branston rural district. Other rural outlying districts have had only one or two cases and then the patients were persons who worked in Lincoln. It is urged that the outlying localities where there has been a considerable number of cases are supplied with the Lincoln water and that the other localities, where there have been very few cases, are not supplied with the Lincoln water. This is a very striking and effective argument; but is it not equally necessary to state that those outlying localities where there has been a considerable number of cases drain into the Lincoln system of sewers, and the other localities where there have been very few cases are not connected with the Lincoln sewers? In other words, the neighbouring villages which have neither the water nor the sewers of Lincoln have escaped and those which have both the sewers and the water of Lincoln have not escaped. It will be seen from the figures given that the present is a severe epidemic, for the estimated population of Lincoln is only 50,500. But there were 39 deaths from typhoid fever in 1879 and the population did not then amount to 35,000. If there should be no further deaths from the present epidemic then the epidemic of 1879 will in proportion to the population have been almost as fatal. Unfortunately, it is probable that the difference between the two epidemics will become more marked before the present outbreak is over. The epidemic of 1879 had been preceded by a very dry year. The dangerous condition of the water-supply has been made the subject of repeated warnings uttered over and over again during the last quarter of a century. The present medical officer of health was particularly strong in his protest 20 years ago. Since then circumstances recalling the present conditions have occurred more than once but not with the same fatal effects. For instance, in his report for the year 1890 Dr. O. Harrison says:—

> As to the use of the [illegible] of water taken at vari[illegible] its way into the [illegible] in its passage d[illegible] the stream was [illegible] age as to be unfit *for domestic pu*[illegible] the water when fully exposed to the air it is easy to understand that the Witham being covered with ice several inches thick for three or four weeks, as it was lately, the water would contain a much greater amount of impurity.

This is very similar to what has occurred this year, yet in 1890 there were only seven deaths from typhoid fever and in 1891 not more than two deaths from this disease. But in the latter year there were some very severe cases of diarrhœa which were attributed to the water. This water was drunk by 750 occupants of the Bracebridge County Asylum and 73 cases of diarrhœa followed just at the time when the river Witham was frozen over. Inhabitants of Lincoln were also inconvenienced in the same way and the water was held responsible because the inhabitants of Upper Bracebridge, some of whom lived within 50 yards of the County Asylum, did not drink the Lincoln water and did not suffer from this epidemic of diarrhœa. The results were not, however, very serious, for including the deaths from infantile diarrhœa there were only 29 fatal cases in 1890 and 14 in 1891. In the following year, 1892, attention was called to the insufficiency of the filtering media and the increased consumption of water. We are not told that the inhabitants let their taps run during the frosty weather so as to prevent the pipes freezing and bursting, but if they did so this year there is no reason why they should not have taken the same precautions in 1890. If in such circumstances the filters were overworked on the present occasion perhaps the same thing occurred then, but these details were not investigated because though very similar causes, so far as the water-supply is concerned, seemed to have been in operation no [illegible]

[illegible] to the reports [illegible] conditions of [illegible] similar to the conditions prevailing during the present winter. Nevertheless there were only a few cases of typ[illegible] [illegible] asked, How did those few persons who suffered from typhoid fever contract the disease? Typhoid fever has always been present at Lincoln. During the ten years 1881 to 1890 there were 87 deaths attributed to this cause, or an average of 8·7 per annum. The population of Lincoln was estimated at 37,313 in 1881 and at 47,061 in 1890. Putting the average population for the ten years at 42,000 and the average annual number of deaths from typhoid fever at 8·7, this gives an annual average death-rate from typhoid fever of 0·2 per 1000 of the population. But it is necessary to remember that in the previous decade, during the year 1879, there was a severe epidemic when 39 deaths from typhoid fever occurred. This, for the population which then amounted to about 35,000, equalled for the one year a death-rate from typhoid fever of 1·11 per 1000. So far the deaths due to the present epidemic amount to 63 and this on the actual population of 50,500 is equal to a death-rate of 1·22 per 1000. The epidemic now prevailing threatens to be more serious than that of 1879 but up to the present the two are about equal in regard to the proportionate number of fatal cases per 1000 of the population. During the next decade, from 1891 to 1900, there were only 70 deaths attributed to typhoid fever, and this in face of the increasing population shows a considerable reduction in the prevalence of the disease. So we have first a decade concluding with 1880 with a serious epidemic. In the next decade there are [illegible] at least where the conditions remain substantially the same. At Lincoln there does not seem to have been any very substantial change during that time in the general system of water-supply and of drainage. It was in 1871 that the corporation bought the waterworks and the present system of sewers was constructed from 1877 to 1881. A number of alterations have been made since then in the sewage settling tanks and the methods of treating the sewage when it reached the sewage farm but that would scarcely influence the dwellers within the city. Undoubtedly the tendency should be to effect a constant improvement in the details of the connexions between the houses and the sewers but this is often marred by jerry-builders. In any case the general system, both in regard to water-supply and drainage, has not undergone any radical change for some 25 years.

With the present decade we find recorded not only the deaths from typhoid fever but the notification of the cases. Thus, in 1901 there were 15 cases notified, resulting in five deaths. Further, and this is most useful, details are given about each case. Of the 15 cases nine were males and six were females. In three cases the disease was contracted outside Lincoln, one patient for instance, had been nursing a case of typhoid fever at Leeds. In regard to the remaining 12 patients sanitary defects were found in the houses inhabited by nine of these cases, and of four new houses inhabited by patients two were defective. There seems to be, so far as these cases are concerned, a connexion between the disease and the insanitary condition of the patient's home. In 1902 there were 13 cases and three deaths. Of these eight were female and five were male. Three of the cases had obviously been imported. Of the remaining ten, three are described as living in dirty, over-crowded places; two of these were in back-to back houses. For the year 1903 we are told that 32 cases were notified, though there were only four deaths from this cause. Unfortunately the details as to the condition of the houses are not given. 14 cases occurred in August after the annual holiday when many people made excursions to the seaside where it is thought that they ate contaminated shell-fish. In 1904 only six cases had been notified before what is generally considered the commencement of the present epidemic. The last of these six cases was notified on Oct. 15th. Then a clerk employed in a brewery—that is to say not a poor man or a man living in a poor quarter—was notified on Dec. 2nd as suffering from typhoid fever. The next case was in the cathedral yard in a very fine house and the sufferer may be qualified as belonging to the wealthy classes. On Dec. 27th there were two more cases. These four first cases were all on the height which is dominated by the minster. On Dec. 28th there were two more cases and the disease now began to make its appearance in the lower part of the city. On the 29th and the 30th there was one case on each day and three cases on the 31st. Altogether there were 11 cases in December, ten of them having occurred since Dec. 22nd. Up to Jan. 23rd cases were notified for 11 out of the 23 days and then only one or two cases excepting on the 7th when there were three cases. On Jan. 24th the epidemic began to assume serious proportions. There were 13 cases on that day and 23 on the following day, on the 28th no less than 59 cases, and 42 and 45 respectively on the two last days of the month. Altogether there were 18 cases up to Jan 23rd and 237 cases during the remaining eight days of the month. The cases occurring in the month of February bring up the total to 745 on the morning of the last day of the month, though there now seems good reason to believe that the epidemic is subsiding.

It is too soon from the data, the facts are not yet clearly ascertained, to pronounce any emphatic opinion as to all the causes of the mischief. Undoubtedly there is every probability that the filters were overworked and that the water, which was obviously contaminated, was allowed to pass when it was insufficiently purified. But there were other factors at work, though it is more difficult to discover and to describe them than simply to denounce the water.

In respect to the question of the water-supply I am requested to explain that although in February, 1903, the tool employed for boring broke work is now being continued with great activity. Instead of boring, the hole made by the instrument, which was two feet wide, has been converted into a well eight feet wide and this is to be continued 800 feet downwards when the position where the boring tool broke will be reached. So that the hope of piercing below the sandstone and reaching an ample supply of pure water has not been abandoned.

March 1st.

Postscript.—The sanitary authorities have just concluded an investigation which I ventured to suggest might be instructive. They have gone over the notification book and examined the cases in respect of age and sex. There has only been one case of an infant below one year of age, but from one to five years there were 25 males and 21 females who contracted the disease; from six to ten years, 85 males and 38 females; from 11 to 15 years, 61 males and 56 females. The total is 172 males and 115 females below the usual age for work. Of the adults between the age of 16 and 25 years there were 137 males and 93 females; from 26 to 35 years, 68 males and 44 females; from 36 years and over, 61 males and 42 females. The total for adults is therefore 266 males and 179 females. Thus it is quite evident that the males are the principal sufferers. It may be said that working in foundries and exposed to the heat of furnaces many men drink a large quantity of water, but this does not apply to youths and children, and why should it be from six to ten years that boys are specially susceptible?

For the last seven days, from Feb. 22nd to 28th inclusive, the number of cases notified daily were 10, 5, 20, 5, 3, 5, and 8, giving a total of 56 cases during the last seven days. During the preceding seven days there were 80 cases and this followed upon 120 cases for the previous seven days. The epidemic, therefore, seems to be gradually subsiding.

(To be continued.)

CHOLERA AND PLAGUE IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE ON THE OTTOMAN BOARD OF HEALTH.)

DURING the past month the cholera epidemic in Asiatic Turkey has been almost confined to Van and its neighbourhood. As reported in my last letter[1] the disease appeared there at the end of December. It has not, so far as may be judged by the official returns, caused a very serious mortality and the outbreak is now apparently at an end. The following are the figures reported during the last five weeks:—

	Cases.	Deaths.
From Jan. 8th to Jan. 13th	14	5
,, ,, 14th ,, ,, 21st	34	7
,, ,, 21st ,, ,, 25th	2	1
,, ,, 26th ,, Feb. 4th	0	0
,, Feb. 5th ,, ,, 12th	0	0

The only other places where cholera has been present in this period have been: the village of Tavile, in the Gulamber district, where on Jan. 9th there were 5 cases with 3 deaths, followed by 6 cases and 5 deaths between the 9th and the 15th of that month; the village of Kerbil, in the *caza* of Mahmudieh, where the disease was reported to be prevalent in the middle of January but from which no figures have been received; and the village of Yabar, in the *sanjak* of Suleimanieh, where 5 cases and 3 deaths occurred on Jan. 14th. It is more than possible that the apparent subsidence of the epidemic in the elevated districts of Turkish Armenia is in part due to the lack of information owing to the cold weather and heavy snowstorms that have been prevailing in these regions.

In Persia there has also been recently a considerable diminution in the cholera outbreak, although—in marked contrast to the weather prevailing in Turkey—the winter this year in Persia is described as being a remarkably mild one, with unusually little snowfall. The following is a summary of the reports received from the Turkish sanitary delegate on the Tehran Board of Health. Writing on Nov. 30th, 1904, he stated that, apart from two cases occurring in connexion with the regiment of recruits mentioned in my last letter, no other cases had recently been observed in Tehran. At Resht 20 deaths a day were still being reported. In Bushire there had been a great improvement during October, the disease having disappeared from Bushire and its neighbourhood and also from Hendian and the island of Kharg, where it had shortly before made its appearance. At Mohamerah there had been a violent recrudescence of cholera in the middle of October, causing a very high mortality but not lasting for long. At Tabriz the mortality had sunk on Oct. 14th to 3 or 4 a day. In a second report, dated Dec. 7th, it was stated that cholera was still prevalent among the fishermen at Enzeli, on the Caspian Sea; at Kazerun 20 deaths were occurring daily; at Kerman the daily mortality was 30; at Kazvin the disease was still present, as also at Siah-el-Mahal and Monteh; and 9 deaths daily were occurring at Kelat. Sporadic cases were still reported from the Ghilan province. The outbreak was diminishing at Kergancroud, Tabriz, Shefa-Rud, Asterabad, and Khoy. It was increasing at Astara, Gheratikan, and Hamadan and its neighbourhood. It had reappeared at Ghalé-Nour, Nouheran, and at Ahr, where 10 or 12 deaths were occurring daily. At Khalifé-Kendé the daily deaths numbered 20 or 30 and at Urumiah 30.

The next report, dated Dec. 14th (quoting from reports received from the Customs authorities, dated Dec. 7th) stated that recent rains had caused a revival of the disease in most of the villages lying between Kermanshah and Hamadan. The first-named town was said to be in a very insanitary state in spite of orders having been given for its improvement. On the 10th of the month the disease was reported to be showing renewed activity at Hamadan where the mortality had risen to 27 daily, at Bender-Guez 12 deaths, and at Kouré-Tour 11 deaths were occurring each day. Another report, dated Dec. 21st, announced the appearance of cholera at Zehab, at Sheraif-Baiani, and among the Djaf tribe of nomads near Suleimanieh. The epidemic at Urumiah was then over, after causing a total mortality reckoned at 1500; at Khaf the outbreak was increasing; at Khoy, where the mortality had risen at one time to 40 or 50 daily, it was diminishing; at Talishé and Tounekaboun 10 deaths were occurring daily in each. The epidemic at Saoutch-Boulak was said to be at end.

The following week's report, dated Dec. 28th, stated that there had been a slight revival of the disease at Mohamedabad, near Meshed, with a daily mortality of 3 or 4. The outbreaks at Kermanshah and at Bender-Guez were at an end. Sporadic cases had been occurring at Shivan (Lingah district) since Dec. 15th and also in all the villages of the Asterabad district. The outbreak at Khoy was still on the decline; the infection was still present at Bellesaar and Ardebil; and its activity at Ispahan was increasing, the mortality there having risen to 30 or 40 daily. The next report, dated Jan. 4th, furnished some details of the outbreak at Khoy. It seems that the disease appeared there on Nov. 20th; up to the 29th of that month the daily deaths averaged about 30; they then began to increase until on Dec. 6th they were as many as 115 in the day. The mortality then diminished but the disease spread to many of the villages in the neighbourhood, especially in a northerly direction. The outbreak there had been checked by the extreme coldness of the weather. At Shapur there had been a severe epidemic but it was then rapidly declining. At Kerman the outbreak had all but completely subsided when, owing to the influx of returning refugees, there was a fresh outbreak of the disease. Cholera was still present in many of the villages of the Khorassan province. At Bujnurd the daily deaths numbered 15; at Kifan 5. At Shirvan they never rose above 16. The disease was then seriously prevalent in several villages near Khaf, the total mortality in all the villages taken together amounting to about 50 daily. The latest report, dated Jan. 11th, mentions the occurrence of sporadic cases at Shuster, with a daily mortality of about 3 or 4, while in the rest of Arabistan the public health was said to be satisfactory. At Nishapur, in the neighbourhood of the turquoise mines, there had been a revival of the disease, as many as 100 deaths occurring in a week. There was a rumour (as yet unconfirmed) that a fresh outbreak had occurred at Kermanshah.

It is of interest to note that in the above reports mention is made of the serious prevalence of small-pox "in all parts of Persia." It appears to have been especially severe in Kerman, where it is said that not a single house has escaped without a case and where not less than 5000 children are thought to have perished from the disease. A mild epidemic of influenza was prevalent in Tehran in the second week of January and other diseases mentioned as present there are diphtheria, measles, scarlet fever erysipelas, malaria, and a few cases of typhoid fever

On Russian territory there has recently been a very marked decline in the cholera outbreak. In Transcaspia, between Dec. 16th and 21st, 3 sporadic cases were observed in Ashbabad and at Tashkent there was only a single case on the 25th. On the 27th a single [illegible] troops at Kaac [illegible] were 6 cases ar [illegible] Transcaucasia the recent course of the epidemic has been as follows. At Baku, Balakhani, and in the Djevat district 17 cases with 3 deaths occurred between Dec. 21st and 28th and, in the Lenkoran district of the Baku government there were 268 deaths between Dec. 14th and 21st and 74 deaths between the 21st and the 28th. Between Dec. 28th and Jan. 9th no figures were published but between Jan. 9th and 15th there were only 4 cases and 9 deaths in the whole of the Baku government. In Tiflis the epidemic is apparently over, no cases having [illegible] uce since Dec. 7th. In the [illegible] a few cases of cholera in [illegible] icious cases on the railway in the following week, and 1 case between Jan. 9th and 15th. In the Erivan government 38 cases and 33 deaths were reported between Dec. 21st and Jan. 1st and 9 cases with 9 deaths between Jan. 9th and 15th.

---

[1] THE LANCET, Jan. 28th, 1905, p. 260.

On the Volga there has been an *equally marked* decline in the epidemic. In the Ast [illegible] occurred between Dec. 20th [illegible] the following week, and [illegible] Saratof government there [illegible] at Tsaritsyn) between Dec. 21st and 27th, 15 cases and 10 deaths in the succeeding week, and 10 cases with 3 deaths between Jan. 9th and 15th. I [illegible] epidemic appears to be at an en [illegible] reported from the Nikolaief d [illegible] 27th.

Some details of the remarkable outbreak of pneumonic plague which (as mentioned in my last letter) recently appeared in the Uralsk province of Southern Russia are now av [illegible] rance in the [illegible] *itzas* or set [illegible] These settlements are situated on the Ural River, in the Gurief district (*uyezd*) of the Uralsk province. How the infection reached them is quite unknown. The first 2 cases, both fatal, [illegible] the disease began [illegible] lies in the neigh [illegible] population. Betwe [illegible] Dec. 26th no less than [illegible] deaths from the disease occurred in the two settlements named. The infection also appeared in a third settlement called Sorotchinsk; in the three settlements together the mortality had risen to 30 per day before Dec. 27th; from that date to Jan. 2nd there were 89 cases and 97 deaths. The figures for the next week have not been published but between Jan. 10th and 16th there were only 3 cases, all fatal. The disease appears also to have spread to the Inner or Bukeëf Horde of Kirghiz, to the west of the Ural, among whom 23 deaths from plague were reported between Dec. 21st and Jan. 13th.

Finally, a serious outbreak of anthrax (Siberian plague or ulcer, as it is called in Russian) is reported from the Viatka government. In the week ending Dec. 21st as many as 86 cases were recorded; in the following three weeks the numbers fell to 47, 46, and 31 respectively.[2]

Constantinople, Feb. 10th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Hospitals.

YEAR by year at the meetings of the subscribers to our various hospitals the same story is told: increase of the demands on their resources, patients flocking to them in greater numbers, and the appliances required for carrying out the treatment of the day more numerous and costly. At the same time removals from the district and the loss of old subscribers by death bring down the list of subscriptions. Wealth increases, judging by lavish, not to say ostentatious, expenditure, and is more widely spread, yet the subscription lists tend to shrink rather than to expand and it seems as if the very generous standard as to the style of living set up by the unwritten middle-class conventionalism of the well-to-do were drying up the springs of charity. The same names occur in the subscription lists of the various charities [illegible] the pecuniary support and active interest shown in [illegible] management are limited too much to a few well- [illegible] families and firms that have for years, and in some cases for generations, been looked to as helpers of those less fortunate than themselves. In the meantime the constant appeals for subscriptions, large or small, to enable these deserving and over-strained charities to pay their way fall upon ears dulled and deadened to indifference by ceaseless repetition. This state of things was illustrated at the annual meeting of the supporters of the Northern (formerly the Clinical) Hospital for Women and Children the other day. It is in a district occupied largely by the "aliens," about whom so much is heard just now, where poverty is more the rule than the exception. The treasurer said that the expenses "had been kept down to a minimum but within the last 20 years there had been a remarkable increase of charitable institutions in Manchester and the older hospitals found it more and more difficult to get the support they needed. The district could not do without that hospital and it must go on as long as there was a penny in the till." There is an average deficit of nearly £1000 a year. With all these numerous charities crying "Give, give," there must be waste, overlapping, and abuse, so that it is to be hoped that a valuable suggestion by the chairman, Mr. Edward Holt, may be acted on. He said: "It would be a good thing if a conference were called by the Lord Mayor with a view to forming a central organisation for the more economical working of all the hospitals in the city and district." If carefully and tactfully managed such an organisation might do much to harmonise discordant and rival interests. It is not seemly nor does it show the spirit of true charity for medical charities to seek for custom—so to speak—and vie with each other as to the number of patients on their lists and it most certainly tends to bring about the abuse of charity by those able to pay.

Are Carlisle's Medical Charities Abused?

The above remarks on the medical charities of Manchester have their bearing on what is found in other places. It is not merely that charities suffer from lessening receipts but those rea [illegible] oo often by large nur [illegible] annual meeting on [illegible] Dispensary some striking facts were given by the Rev. Chancellor Prescott who said that when they added the total of their patients, 4825, to the 2882 out-patients attended at the Cumberland Infirmary they found there were between 7000 and 8000 persons receiving gratuitous medical attendance out of a population of 45,000, and this without taking into account those attended by the Poor-law medical officers. He thought this far too large a number and "the question arose whether people were receiving free medical attendance who ought not to be" If this is not the case Carlisle would seem to be very far from prosperous. It was suggested that a committee representing the various charities should inquire as to the existence of abuse. Is the old spirit of self-reliance and self-help departing and are the people becoming pauperised?

Small-pox.

Dr. J. Niven, the medical officer of health, was able to announce last week that Manchester is free from small-pox and this for the first time since the end of 1903. There are, however, said to be about 18 cases in Droylsden on the outskirts.

Royal Infirmary.

At the meeting of the infirmary board yesterday the architects reported that it was hoped to send the first bills of quantities to the competing contractors almost at once, that they would be in their hands by the end of March, and that the tenders might be expected to be in by the middle of April. A correspondence has taken place between the corporation [illegible] er of the Piccadilly site. The [illegible] provision made at the Stanley [illegible] The chairman of the [illegible] afterwards adopted, to [illegible] ct of 1903. The sch [illegible] afford twice the accommodation of the present one and when it was ready possession was to be given to the corporation. But as the Act imposed they would have to proceed with due diligence.

---

[2] All the dates mentioned in this, as in the preceding letters, are according to the New Style

It was to their own financial advantage that the work should be carried on as expeditiously as possible and due diligence would be used.

Feb 28th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The Leeds Workpeople's Hospital Fund.

THE seventeenth annual meeting of the supporters of the Leeds Workpeople's Hospital Fund has been held. Prior to 1887, when this fund was commenced, the medical charities received the workpeople's subscriptions through various channels and it was felt that if properly organised efforts were made and all subscriptions were paid into a common fund the amount obtained from the workmen of Leeds would be increased to a considerable extent. That this has been the case is shown by the fact that the total income for the year 1904 has amounted to the sum of £11,236, which with the balance brought forward from 1903 raises the total amount at the disposal of the committee to £12,565. During the 18 years of its existence the committee of management of the fund has admitted from time to time additional charities to benefit by the annual distribution of grants and some few years ago a new departure was taken when it was decided to institute convalescent homes to be acquired and to be supported from the general fund. At the annual meeting the following grants were decided on: Leeds General Infirmary, £5000; Leeds Public Dispensary, £750; Hospital for Women and Children, £750; Tuberculosis Association, £280; District Nurses' Association, £225; and some smaller grants. A sum of upwards of £2000 was carried to a reserve fund for the extension of convalescent homes.

The Sale of Poisons.

As was mentioned in my letter on Jan. 21st a fine was imposed on a Bradford druggist who was prosecuted by the Patent Medicine and Drug Vendors' Association for having sold Rankin's ointment. This preparation contains veratrine and it was held that the defendant had "sold a poison—to wit, veratrine—to a person then unknown to you, and not introduced by a person known to you." The case has been taken to the Court of Appeal. A case on precisely similar lines was heard by the Leeds stipendiary magistrate in which 15 chemists and druggists were charged with selling the same ointment under the same conditions. In evidence it was stated by Mr. F. W. Richardson, analyst, that the ointment contained 1·06 per cent. of veratrine, which represented a total amount in the box examined, which was one of those purchased, of 2⅖ grains. The stipendiary intimated that he would reserve judgment until the Court of Appeal had given its decision in the Bradford case. The defendants were also charged with selling Easton's syrup, which, of course, contains strychnine, under conditions at variance with the Act, but the hearing of this part of the cases was adjourned. At the instance of the Inland Revenue authorities a "general dealer" was summoned for selling a preparation liable to stamp duty without a stamp and without a licence. The preparation in question was that known as "daisy powders" which are believed to consist of antifebrin. The former charge was withdrawn as a conviction was obtained on the latter.

Professor Sims Woodhead on Temperance.

Professor G. Sims Woodhead is so well known to the medical profession that one was not surprised to find that an invitation issued to its members by the Lord Mayor of Leeds to hear him speak on "An Aspect of Physical Degeneration" was largely responded to. Professor Sims Woodhead introduced his subject by commenting on the report of the inter-departmental committee, saying that if actual degeneration in the national physique was not going on there was at least an interference with that natural rate of improvement which might be expected under improved conditions of sanitation. As causes of deterioration we had extreme luxury on the one hand and extreme poverty on the other, but with both was associated an excess in the use of alcohol. Luxury and alcoholism had a lowering effect on the birth-rate of the country and militated against the good nutrition of the child after birth. By lowering the wage-earning power of the parents and by using up money which otherwise might be spent on food alcohol lessened the chance which children had of being adequately fed. He also maintained that experiments, carefully conducted, had demonstrated that alcohol taken in amount much below what was usually regarded as excessive interfered with efficient brain work and he pointed to the fact that total abstainers were able to insure their lives at a lower rate than those who were not abstainers. Of course, it does not require Professor Sims Woodhead or anyone else to convince any thinking body of medical men that excess in the use of alcohol is damaging to the individual and to the nation on every ground, but opinions certainly do differ as to the precise point at which such excess begins. It had been announced that a discussion would follow on the paper and some disappointment was occasioned by the Lord Mayor stating that there was unfortunately no time for this. As between total abstinence and excess no one can hesitate but there are many thinking men who maintain that as against total abstinence a strict temperance is as favourable to health and is even a higher moral position.

Appointments at the University and Medical Institutions.

Dr. E. F. Trevelyan, who lately retired from the professorship of pathology, has been appointed to the lectureship on therapeutics and materia medica. Dr. A. E. Porter, the assistant medical officer of health of the city, has been appointed demonstrator of public health under Professor J. Spottiswoode Cameron. The election committee of the Hospital for Women and Children has selected Mr. J. F. Dobson for the new appointment of assistant surgeon for children, and the authorities of the Public Dispensary have secured the services of Dr. Oskar C. Gruner for the new post of honorary pathologist.

Feb. 28th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Public Slaughter-houses and Meat Inspection.

AT a meeting of the West of England and South Wales branch of the Incorporated Society of Medical Officers of Health held at Newport (Mon.) on Feb. 23rd Dr. J. Howard-Jones (medical officer of health of Newport) contributed a paper upon Public Slaughter-houses and Meat Inspection. The principal requirements necessary in a public slaughter-house he considered to be nearness to a cattle market and railway station to which a connecting siding should be constructed, a lairage with separate stalls and water-tight flooring, well-lighted and properly ventilated killing-rooms with impervious but not too smooth floors laid to a slope, absence of wooden fittings, the removal of waste in sealed wagons, separate stalls for hospital use and for killing and storing suspected carcasses, ample water-supply, and the provision of a destructor for treating inferior and condemned meat. Among 1083 towns in England and Wales there are at the present time only 84 public slaughter-houses. Included in this latter number are Cardiff, where there is no private slaughtering, and Newport and Swansea, where there are only two private slaughter-houses. London does not possess one public slaughter-house but has about 600 private ones. The value of the meat condemned annually in Newport is about £200. The system of insurance which has been in force in the town during the past two years was spoken of in favourable terms. The scheme involves the payment to the auctioneers by the dealers or farmers of 1*s.* per head of cattle sold. The auctioneers pay to the butchers two-thirds of the value of the animal thus insured in the event of its seizure and condemnation owing to the presence of tubercle. The unsatisfactory system of meat inspection in country districts was commented on by Dr. Howard-Jones who urged that no meat brought into a town which is provided with a public slaughter-house should be offered for sale until it had been inspected at the public slaughter-house and that every such carcass taken for inspection should have attached to it the heart, lungs, liver, and kidneys.

Merthyr Municipal Houses.

At the same meeting of the society Mr. D. J. Thomas (medical officer of health of Merthyr Tydvil) gave an account of the steps which had been taken by the urban district council of Merthyr to supply workmen's houses in that town.

In March, 1900, the council decided to build 100 such houses and secured suitable land for a term of 999 years at an annual rental of three-halfpence per square yard. The houses were built by contract for £15,950, but the making of the streets, law charges, payment of royalties for stone, gas fittings, and payments to the clerk of works involved an expenditure of another £2000, so that each house has cost £170. They are let at an inclusive rental of 22*s.* 6*d.* per month. The area at the rear belonging exclusively to each house measures 545 square feet. The houses are built in eight blocks on both sides of two streets 30 feet wide, with a secondary means of access 10 feet wide at the rear. A house contains on the ground floor two living rooms and a pantry and on the first floor there are three bedrooms. There are a separate coal-house and water-closet for each house. Mr. Thomas admitted that these houses at Merthyr did not meet the wants of a large class of men who, as labourers, earned less than 20*s.* a week and could not afford to pay in rent more than 3*s.* or 3*s.* 6*d.* a week, and he discussed the desirability of securing some of the more satisfactory of the older and insanitary property and by extensive repairs making them reasonably fit for human habitation. The requirements of the large number of single men who find employment in the ironworks and collieries he thought might be met by the provision of large lodging-houses of a better stamp than ordinary common lodging-houses.

The Medical Officer of Health of Gloucester.

At a meeting of the sanitary committee of the Gloucester city council held on Feb. 10th Dr. John Campbell handed in his resignation as medical officer of health of the city and port sanitary authority and asked to be relieved of his duties by March 25th, when he is about to leave the town. At a subsequent meeting of the committee it was decided to recommend the council to appoint a medical officer of health for the city and port at an inclusive salary of £400 per annum, his duties to include attendance at the isolation hospital and other duties to be formulated by the education committee. This recommendation was referred to the committee at the meeting of the council on Feb. 22nd in consequence of a communication received from the Local Government Board. The Board stated that it had come to the conclusion that where a sanitary authority secures the whole-time services of a medical officer of health whose training has had special concern with public health work apart from his ordinary professional qualifications it is desirable to insure that his position will be such as to enable him (1) to perform his important duties impartially and independently; and (2) to be regarded as in no way inferior to that of other medical men who are engaged in the general practice of their profession. It was further added that the Board was of opinion that the total salary of a medical officer of health who is so qualified and who devotes his whole time to his duties should not be less than £500 per annum. Dr. Campbell's salary was £250 per annum but he was not debarred from private practice.

Royal West of England Sanatorium at Weston-super-Mare.

The annual report of this convalescent home is usually of a satisfactory nature both as regards the amount of financial support given to it and the number of patients who receive permanent benefit from residence in the institution. In the early part of 1902 the whole of the drainage system was remodelled at a cost of about £2000 and the sanatorium was closed for four months while this work was being carried out. During the remaining eight months of that year 1668 patients were received, in 1903 there were 2254, and in 1904 there were 2353. Of these last 1140 were discharged fully recovered, 546 were much improved, 467 were improved, 62 were much the same as on admission or no better, one died from heart disease, and 120 were unfit cases for the home. The expenditure during 1904 amounted to £3904 and the income was £3838. At the general meeting of the subscribers held on Feb. 18th Dr. E. H. W. Swete drew attention to the number of patients sent in who were unsuitable for treatment in the sanatorium; he also referred to the excellence of the institution for the treatment of cases of pulmonary tuberculosis in the earlier stages of the disease. The sanatorium buildings are very well placed at the end of the promenade and overlook the Bristol Channel.

The Lord Chief Justice on Habitual Criminals.

When charging the grand jury at the Gloucestershire assizes on Feb. 18th the Lord Chief Justice said that he had for a long time been of opinion that habitual criminals or those who had sunk so low that imprisonment had no deterrent effect upon them should be detained in institutions other than prisons. He referred to them as persons who had a twist in their composition and upon whom prison discipline appeared to have little or no effect, who would never voluntarily work, and if allowed their liberty inevitably returned to crime for a livelihood. He asked the grand jury to express an opinion as to whether some alteration might not be made in the existing treatment of this class of criminals. It was a question, he said, which was being considered by His Majesty's judges and by the Home Secretary.

Action at Law against the Clevedon Urban District Council.

At the Bristol assizes, before Mr. Justice Lawrance, a jury awarded £50 as damages to the owner of some houses at Clevedon who alleged that his property had been depreciated in value owing to the negligence of the district council in not keeping in repair a sewer which was in proximity to the property and which caused considerable flooding of the premises.

South Devon and East Cornwall Hospital.

The annual meeting of the subscribers to this institution was held at Plymouth on Feb. 21st. The medical report stated that 1251 in-patients were admitted during 1904 as compared with 1336 in 1903, the out-patients for the corresponding periods being 3369 and 2976 respectively. The daily average number of in-patients was 119. The financial statement showed that the ordinary income, excluding legacies, amounted to £7631. The legacies received during the year were £8697 and enabled the committee to pay off the deficit on the current account for 1903 and 1904 and also to set apart an ample sum for investment. The ordinary expenditure was £8657.

Feb. 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THE honorary Fellowship of the Royal College of Surgeons in Ireland was formally conferred on Dr. Anthony Traill, the Provost of Trinity College, on Feb. 25th, when he signed the roll as an honorary Fellow of the College. At the subsequent annual dinner the President, Mr. A. Chance, read a letter of apology from His Excellency the Lord Lieutenant which stated that he was obliged to go to London and said that no inference of a political character should be drawn from his regrettable absence. The toast of "The King," which was
usiastically honoured, as was
the Lord Lieutenant." The
Vice-President, Mr. H. R. Swanzy, proposed the toast of "The Provost—the new Honorary Fellow of the College." In reply, the Provost made a most interesting speech, in which he briefly traced the history of Trinity College since its beginning in the reign of Queen Elizabeth, referring especially, of course, to the long list of provosts who preceded him. "I take it," he said, "that this honour has been conferred upon me as a compliment to me as provost of Trinity College but principally because I occupy a unique position as the first medical and surgical provost since the foundation of the College by Queen Elizabeth. I am a Doctor in Medicine and also a Master in Surgery." In conclusion, the Provost said that there were 35 provosts since the College was founded and that during all those years there were only four lay provosts. Of himself he could say that he was the first to hold the degree of M.D. and M.Ch., which had that evening received the kindly recognition of that famous corporation. In reply to the toast of "The Guests," proposed by Sir Charles Cameron, Sir Antony MacDonnell delivered a clever speech which, however, was carefully reticent.

Royal National Hospital for Consumption for Ireland.

overnors of the Royal
s held in the hall of
nd on Feb. 24th, Mr.
e chair. In moving
said that it was of a
at last succeeded in
100 poor patients at
Newcastle, co. Wicklow, and that it was now occupied by 95 inmates. The adoption of the report was seconded by the

President of the Royal College of Physicians of Ireland. The Registrar-General, who was present, said that for the year 1903, the last year for which they had detailed figures, tuberculous disease stood at the head of the causes of death, the number of patients who succumbed to that malady in Ireland being 12,180, or 2·8 per 1000 of the estimated population. This showed an increase when compared with the previous year, 1902, the rate for which was 2·7 per 1000. What he stated sufficed to show the urgent need for a collective effort to combat the ravages of this dreadful scourge.

The Milk Question in Belfast.

AT a meeting of the Belfast public health committee held on Feb. 16th a deputation of citizens was received who urged that the Belfast city council should take steps to adopt stringent rules in reference to the milk-supply of Belfast. It appears that there is some power to control the milk trade in the city but no laws exist in reference to the milk coming from the surrounding districts outside the Belfast area. It is reported that the Vice-President of the Irish Agricultural Board, Sir Horace Plunkett, was urged to try to establish in various parts of Ireland dairies on the modern Danish system which would serve as object lessons to show how pure milk could be obtained and, it is said, he was willing to act with the municipal authorities. An immense deal needs to be done by the Belfast health authorities in reference to the milk problem which has been engaging so much of the attention of other municipalities in the United Kingdom. At a meeting of the public health committee held on Feb. 23rd the following motion was carried:—

> That, with a view of combating tuberculosis, the council be recommended, when [illegible] a bill in Parliament to include provisions giving power to [illegible] the supply of milk from any dairy inside or outside the city if their medical superintendent officer of health is of opinion that tuberculosis is caused, or is likely to be caused, to persons residing in the city, from consumption of the milk supplied from such dairy.

But, as pointed out in a local paper, the resolution does not go far enough, inasmuch as tuberculosis is not the only disease that may be transmitted by milk (it is probable that it is the least frequent disease conveyed directly by milk to man) and further, it is simply begging the question to do nothing until another Bill in Parliament is promoted (which may entail a delay of years) when by applying directly to the Local Government Board for a special order in the matter some immediate steps might be taken to insure a proper control of the milk-supply of Belfast, a procedure which should have been taken years ago.

The New High Sheriff of Belfast.

Dr. H. O'Neill, the first medical high sheriff of Belfast, was sworn in as high sheriff of the county and city of Belfast on Feb. 23rd and was afterwards in the police courts congratulated by the magistrates and the members of the legal profession. He has signalised his entrance upon the duties of his office by contributing the following sums to medical charities: Royal Victoria Hospital, £50; Mater Infirmorum Hospital, £10; Forster Green Hospital, £5; Home for the Blind, £5; Maternity Hospital, £5; Day Nurseries, Belfast, £5; Society for Providing Nurses for Sick Poor, £5; Samaritan Hospital, £5; Presbyterian Orphan Society, £5; Protestant Orphan Society, £5; and Domestic Mission to the Poor, Belfast, £5.

Royal Victoria Hospital, Belfast.

At a meeting on Feb. 15th of the board of management of the Royal Victoria Hospital, Belfast, it was moved by Mr. James Davidson, the treasurer, seconded by Professor J. W. Byers, and carried unanimously, that another unit consisting of 32 beds should be opened. This will be of great advantage to the medical staff, owing to the great difficulty at present to find beds for patients.

The Samaritan Hospital, Belfast.

At the annual meeting of the friends of this charity held on Feb. 20th it was reported that there had been during the year 435 extern and 134 intern patients, and of these latter 118 required surgical operation. Seven patients had died in hospital during the year. Financially there was a debit balance at the beginning of the year of £230 2*s.* 10*d.*, and at the end there was a debt of £191 15*s.* 10*d.* There are, however, investments amounting to £3110. Appreciatory speeches were made in reference to the good work done in the hospital. Dr. J. St. Clair Boyd was re-elected one of the honorary surgeons to the hospital.

The Irish Medical Association.

In several of the Irish daily newspapers reference has of late been made to the report presented to the council of the Irish Medical Association by its special commissioner, Surgeon-General G. J. H. Evatt. This report has never yet been circulated among the members of the Association, many of whom subscribed to a special fund to pay for the expenses of the commissioner. The main body of the profession are most anxious to see the report and feel aggrieved that a few privileged people are allowed publicly to discuss its contents while they remain in ignorance.

Feb. 28th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Tuberculous Milk.

AT a recent meeting of the Academy of Medicine M. Moussu read a paper upon the above subject with a view to affording an answer to the question as to whether tuberculous milk is or is not harmful. According to French law such milk may be sold for food if the tuberculous lesions in the cow are not very marked and provided that the teats are not affected. M. Moussu's experiments go to disprove this view and to show that the tolerance extended to such milk constitutes a real danger. By centrifuging tuberculous milk he was able to collect bacilli which when injected into animals rendered them tuberculous. Of five calves which were fed upon tuberculous milk two became tuberculous. From these results then it would appear that an alteration in the law is desirable.

An Apparatus for employing Continuous Extension in Fractures of the Leg.

Hitherto oblique fractures of the leg have been as a rule treated with the continuous extension apparatus of Hennequin. On Feb. 8th M. Nélaton showed to the Society of Surgery for M. Ombredanne an apparatus devised by the latter. M. Ombredanne's apparatus differs from that of Hennequin in that the plaster boot employed by the latter is replaced by one made of felt, by which the liability to pressure sores is avoided. The plaster channel (*gouttière*) of the Hennequin apparatus is also modified so that there is no danger of any antero-posterior movement.

The Eventual Results of Resection of the Head of the Femur in Irreducible Dislocation of the Hip-joint.

At the meeting of the Society of Surgery held on Feb. 15th M. Walther showed a man upon whom ten years previously he had performed Ricard's operation, excision of the head of the femur, for an old irreducible dislocation of the hip-joint. Despite a shortening of nine centimetres in the affected limb the man was able to walk well, thanks to a high-soled boot. The movements of the joint were very satisfactory and it appeared that a new head had been formed at the expense of the neck of the femur, which had been placed in the acetabulum.

Radium in the Treatment of Skin Diseases.

At a meeting of the Hospitals Medical Society held on Feb. 10th M. Danlos said that in his experience radium was of value in only three kinds of skin disease, namely—tuberculous leprosy, a form of epithelioma (*épithelioma perlé*), and vascular nævus. He added that radium is of value in these diseases only in cases where they exist in a very limited form. Moreover, it is not superior to older methods of treatment. When the lesions in which it is of use are widely spread the x rays give better results and radium possesses merely a provisional superiority for use in cavities such as those of the nose or the larynx which are difficult to reach with the x rays. If, however, radium were to become cheaper it would probably be preferred to the x rays, for its application is much simpler and practically no apparatus is required. But until such a desirable condition is a reality it may be said that the future is with radium and the present with the x rays.

Urban Sanitary Regulations.

A police magistrate has recently given judgment in a case in the following circumstances. Manufacturers of ice are legally liable to deliver such ice in vans which are plainly labeled, "Ice for human consumption," or "Ice not for human consumption." This edict annoyed certain manufacturers who found a way of evading it. Accordingly, one of them was summoned by the police and was fined five francs.

Feb. 28th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Berlin Court of Honour.

THE Berlin Medical Chamber has published an interesting statistical summary of the work of the court of honour connected with the chamber. The report says that in 1904 there was 1607 medical men under the jurisdiction of the Berlin court of honour which includes the city of Berlin and the province of Brandenburg. The number of cases standing over from the preceding year as not yet settled on Jan. 1st, 1904, was 82, whilst 166 new informations were lodged against medical men during the year 1904. 60 informations came from private persons, 42 from public authorities, 55 from other medical men, six were anonymous, and in three cases medical men asked the court to give a judgment in doubtful questions of medical etiquette. Of these 248 informations 121 proved at once to be unfounded, in 11 a penalty was inflicted without formal proceedings being taken, and in six cases the court declared itself incompetent to deal with the charge. In 27 cases a formal trial took place before the court. In six of these the proceedings came to an end without judgment being pronounced as the accused was found to be innocent; in 13 cases a verdict of "Not guilty" was pronounced; one warning and two reprimands were given. In four cases the accused were reprimanded and directed to pay fines varying from 100 to 300 marks (from £5 to £15); and in one especially grave case in addition to a reprimand and a fine of 3000 marks (£150) the privilege of voting in the elections was withdrawn. Apart from the disciplinary proceedings, the court was asked in 41 cases to settle controversies between medical men. The number of 248 penal cases appears to be rather great in comparison with the total number of 3607 medical men in Berlin and the province of Brandenburg and to be a much higher proportion than the number of penal cases brought before the British General Medical Council which has jurisdiction over all the medical men of the United Kingdom. It must be remembered, however, that the state of the law is different in the two countries. Whereas the General Medical Council has to pass judgment only in cases of "infamous conduct" and to decide whether the offender's name is to be erased from the Register the duties of the courts of honour in Germany are more complex though their power is less than that of the General Medical Council. Cases which in England can only be decided by the courts of law, such as actions for the recovery of fees, may in Germany be brought before the courts of honour. It is worthy of note that in the great majority of cases the court did not open a formal prosecution against the accused because the question was not believed to have anything to do with professional etiquette. It is easy to molest a German medical man by informations lodged against him as he may eventually be asked to justify his conduct; the court will accordingly decide whether a formal prosecution is necessary or not. On the other hand, even when gross misconduct is proved the courts of honour have only the power to fine a medical man but not to deprive him of the status of a [illegible] case in England. On [illegible] to be preferable, being [illegible] less harassing to the [illegible]

Inoculation of Medical Men with Syphilis at Surgical Operations.

At a recent meeting of the Berlin Medical Society Dr Blaschko read a paper on the above subject. He said that he had himself observed 12 cases of syphilis contracted by medical men in the course of professional work; the liability of practitioners to contract the disease was therefore rather considerable. The primary ulcer as a rule was situated on a finger and early diagnosis was somewhat difficult, the lesion being mistaken for furuncle, herpes, and tubercle. Infection took place either by wounds sustained at operations on syphilitic patients or when at an examination of such patients the virus entered through a small fissure of the skin. In one case infection occurred at a necropsy. There was no absolute protection against such an accident; a too energetic disinfection of the hands by chemical agents should even be avoided because the skin became rough and full of fissures; plain washing with hot water and soap was sufficient. Lesions of the skin must be cauterised by nitrate of silver or tincture of iodine and protected by adhesive plaster and collodion. When symptoms of constitutional infection were developed medical men were apt to become somewhat despondent and to be haunted by apprehensions of tabes and progressive paralysis. The cases of syphilis observed by Dr. Blaschko in members of the profession were, however, far from being serious. The question whether a syphilitic practitioner might continue to practise was not easy to answer. Theoretically he of course ought to abstain from doing so but this was scarcely possible for the great majority of medical men. A medical man ought, however, to abstain from surgical work as long as a primary ulcer existed on his finger.

Neurasthenia in a Russian Naval Officer.

An interesting case was shown by Dr. Holländer at a recent meeting of the Berlin Medical society, the patient being a lieutenant in the Russian navy who took part in the defence of Port Arthur and eventually suffered from neurasthenia after an attack on his vessel in the course of which two Japanese sailors tried to strangle him. To escape suffocation he threw himself, together with his assailants, into the sea, became unconscious, and only awoke three weeks afterwards in a Japanese hospital. When Dr. Holländer saw the patient he suffered from marked spasm of the respiratory muscles, fainting fits, and hystero-epileptic convulsions. As the dyspnœa gradually increased and the patient was likely to die from suffocation Dr. Holländer performed tracheotomy, the result being that the respiration at once became normal and when the cannula was removed 12 days later the dyspnœa had totally disappeared. The spasms recurred afterwards but they were comparatively mild and took place only at long intervals.

Feb. 27th.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Hermann Gutzmann has been recognised as *privat-docent* of Internal Medicine.—*Brussels:* Dr. Jean Coppez, Director of the Ophthalmological Clinic, is retiring.—*Innsbruck:* Dr. Franz Bruno Hofmann, assistant to Professor Hering of Leipsic, has been appointed to the chair of Physiology which has been vacant since the death of Professor von Vintschagau several years ago.—*Marseilles:* Dr. Guende has been promoted to the professorship of Clinical Ophthalmology and Dr. Perrin to that of Clinical Dermatology.—*Naples:* Dr. Donato Greco has been recognised as *privat-docent* of Surgery.—*Odessa:* [illegible] been promoted to the ordinary [illegible] and Dr. A. V. Korsh to that of [illegible] Dr. Segond, *agrégé*, has been promoted to the professorship of Operations and Appliances.

UNIVERSITY OF OXFORD.—In a Convocation held on Feb. 21st the University formally accepted the offer of Mr. Alfred Beit to found a professorship, lectureships, and a prize for an essay in colonial history and recorded its deep gratitude to him for his munificence.—The examination for the degrees of B.M., B.Ch., will commence on Thursday, June 22nd, and will be held in accordance with a time-table published in the University *Gazette* of Feb. 21st.—Natural science scholarships are announced for competition as follows: March 14th, Keble College; May 2nd, Merton College and New College; and July 4th, Brasenose College.

LITERARY INTELLIGENCE.—Two books have just been issued by Messrs. J. and A. Churchill which are of interest to lecturers on medicine and human physiology. "A Text-book of Physiological Chemistry," by Dr. Charles E. Simon, late assistant resident physician at Johns Hopkins Hospital, Baltimore, is designed as a text-book for the lecture room and as a guide in the physiologico-chemical laboratory. In the first section of the work a general survey is given of the origin and the chemical nature of the three great classes of food-stuffs and also of the most important products of their decomposition; the second section deals essentially with the processes of digestion, resorption, and excretion; while the third portion of the work is devoted to the chemical study of the elementary tissues and the various organs of the animal body, the specific products of their activity, and their relation to physiological function. "A German-English Dictionary of Terms used in Medicine and the Allied Sciences," by the late Mr. Hugo Lang, edited and completed by Dr. Bertram L. Abrahams, assistant physician to the Westminster Hospital, is issued by the same firm. Great care has been used in the completion of the work which is the only recent one of the kind available to students.

VACCINATION GRANT.—Mr. H. C. P. Masser, M.R.C.S. Eng., public vaccinator of the Foleshill and Sowe and Stoke districts of the Foleshill union, has again received the Government grant for successful vaccination.

THE LATE MR. A. K. CROSSFIELD.—An excellent painting of the late Mr. Arthur Kyffin Crossfield, L.R.C.P., L.R.C.S. Edin., has been presented to the Dartmouth Cottage Hospital by the committee of that institution in memory of the valuable services which he rendered to the hospital as one of the honorary medical officers. The picture will be hung in the committee room.

OBSTETRICAL SOCIETY OF LONDON AND THE EXAMINATION OF MIDWIVES.—The last examination of midwives held by the board established by the Obstetrical Society of London for the purpose took place last week, concluding with the oral examinations on Feb. 23rd and 24th. There were 674 candidates. 559 passed and will receive the society's certificate. Since the institution of the board in 1872 the grand total of candidates amounts to 12,805, of whom 10,581 have received certificates. The examination of midwives will be conducted henceforth by the Central Midwives Board.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, MARYLEBONE-ROAD, N.W.—The annual meeting of governors of, and subscribers to, Queen Charlotte's Hospital was held on Feb. 27th, Mr. F. W. Hunt presiding. The chairman referred to the great loss that the hospital had sustained by the death of the Earl of Hardwicke who had ably filled the office of chairman of the committee for over six years. The report stated that 1456 women had been delivered in the hospital during 1904 and 1754 had been attended and nursed in their own homes. The ordinary expenditure had amounted to £5829, whereas the ordinary income was £5093 only, including £500 from King Edward's Hospital Fund and £683 the proceeds of the concert given by Madame Melba in aid of the hospital. The legacy under the will of the late Edmond Dresden, to form the "Dresden Assistance Fund" (to be applied solely for the purpose of assisting patients on leaving the hospital), had been received and would enable the committee to help a considerable number of necessitous patients. In order to provide for the increased number of patients and nurses the Nurses' Home had been enlarged by purchasing three houses adjoining the home and three rooms in the hospital had been converted into wards, increasing the total accommodation for patients to 69 beds. An expenditure of over £4000 had thereby been incurred, towards which the committee earnestly appealed for contributions.

CENTRAL MIDWIVES BOARD.—The members of the Central Midwives Board met on Feb. 23rd at 6, Suffolk-street, Pall Mall, London, Dr. F. H. Champneys being in the chair. A letter was received from the clerk of the Lindsey county council inclosing a copy of a resolution of the Midwives Act committee of that council regretting that the stringency of the regulations of the Central Midwives Board involves the retirement from practice on April 1st next of a large number of midwives who have hitherto satisfactorily discharged their duties. It appeared that in Lindsey only five women out of a total of 94 carrying on the work of midwives have applied for certificates under the Act. The clerical work required by the Board's regulations seems to be objected to specially by these women. As the Central Midwives Board has no dispensing power the secretary was directed merely to acknowledge the receipt of the letter. A letter was received from the Herefordshire County Nursing Association inclosing a copy of a resolution passed by the general county committee of that association protesting against the rule prohibiting a midwife from undertaking the duty of laying out the dead. It was asserted that the usefulness of the midwives in country districts was thereby seriously hampered. The secretary was directed to write stating that the resolution has been taken note of by the Board. On the motion of Miss R. Paget, seconded by Mr J. Latter, the Board resolved "that no institution with les than 75 deliveries annually shall be approved as a trainin school." The total number of women on the roll of mid wives on Feb. 23rd was 15,490.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Public Health Acts Amendment Bill.

The object of Sir ALFRED HICKMAN'S Bill to amend the Publ Health Acts, to which reference was made in THE LANCET Feb. 25th, is to save corporate bodies the expense of obtaining Ac of Parliament to enable them to deal with various matters such sanitary provisions, streets, buildings, sewers, infectious disease milk-supply, common lodging houses, and recreation grounds. I previous sessions the Bill was twice read a second time; it was al referred to a select committee and finally adopted by the Governme which promised to legislate in the King's Speech of 1903.

Registration of Nurses.

Mr. MUNRO-FERGUSON has introduced a Bill to regulate the qua fications of trained nurses and to provide for their registration. It h the support of Dr. R. FARQUHARSON, Mr. R. B. HALDANE, Sir THOM WRIGHTSON, Sir JAMES JOICEY, Mr. HUGH CRAWFORD SMITH, M BLACK, Mr. EVE, and Dr. E. C. THOMPSON.

The Pharmacy Bill.

The text of the Pharmacy Bill, which was brought in last week Mr. LOUGH, has now been circulated amongst Members, together with memorandum which summarises the objects desired as follows:—(*a*) check the modern and growing practice on the part of a duly qualifi person to open and to carry on divers shops for the sale of poisons where adequate protection is not afforded to the persons frequenting the su by providing that every such shop shall be under the *bonâ-fide* person conduct and supervision of a duly qualified person; (*b*) to p an end to the abuses at present attending the hawking of poiso and better to regulate the sale of the same by providing th no poison shall be sold except in a shop which shall first ha been duly registered; (*c*) to provide for the maintenance of a regist of shops where poisons may be sold and also a register of the dr qualified druggists *bonâ fide* conducting each such shop, and to enal the registrar from time to time to make corrections in, and additions the same; (*d*) to provide that the compounding of prescriptions sh be in the hands only of persons duly qualified to sell "poisons"; (*e*) require that companies keeping open shops for the sale of poisons sh have that portion of their business managed by a duly qualified drugg as director; (*f*) to extend to corporate bodies certain of the provisic of the Pharmacy Acts, 1852 and 1868, from which they are at present exempt by reason of the decision of the House of Lords in the case The Pharmaceutical Society *v.* The London and Provincial Supply Association, Limited, Law Reports, 1880, Appeal Cases, 857; and (*g*) to facilitate the examination of persons desiring to qualify as chemists and druggists and to enable the Pharmaceutical Society to accept certain certificates of kindred bodies in lieu of examination.

Housing of the Working Classes.

A Bill to amend the Housing of the Working Classes Acts and otherwise to facilitate the building o houses for the working classes in rural districts has been read a first time at the instance of Sir WALTER FOSTER.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 22ND.

Ventilation and Sanitation at Westminster.

Mr. WYLIE asked Lord Balcarres, as representing the First Commissioner of Works, what had been done during the recess for improving the ventilation and sanitary arrangements of the House of Commons buildings; and what, if anything, still remained to be done to fulfil the recommendations of the committee's report on this subject.—Lord BALCARRES replied: During the recess the recommendations of the select committee of the House of Commons with reference to the ventilation have been carried into effect with the exception of the completion of the extract fan. This has been delayed by reason of structural difficulties incidental to the floor of the Commons lobby chamber but it is expected that this fan will be running within a month from the present date. The principal improvements already effected are: (1) the complete washing of the air by means of a new type of water screen; (2) the erection of a much more powerful intake fan; and (3) the more effective isolation of passages joining the main airways. This will be followed by experimental tests having in view the better distribution of air to the Chamber and also by tests of the air so distributed. It is hoped that the works already completed will result in a very considerable improvement in the quantity and the quality of the air-supply.

The War Office and Medical Science.

In the debate on the amendment to the Address which raised the question of army reform Sir WALTFR FOSTER discussed the lessons in connexion with the applications of medical science to be drawn from

THURSDAY, FEB. 23RD.

Vaccination Exemption Certificates.

Mr. WEIR asked the Home Secretary whether he was aware that Mr. James Richards of Tunbridge Wells appeared on six different occasions before the local bench of magistrates before he could procure a certificate of exemption from vaccination for his infant child and, seeing that on each occasion he based his objection on the same ground, would he consider the advisability of directing the attention of the bench of magistrates to the remarks made by the Lord Chief Justice on July 27th last when addressing the grand jury at Birmingham relative to the principle on which the Act ought to be administered.—Mr. AKERS-DOUGLAS replied: I have no information respecting the case referred to. The attention of magistrates has already been drawn by a circular issued in September last to all justices' clerks to the

Heavy Infant Mortality in Egypt.

Mr. WEIR asked the Under Secretary of State for Foreign Affairs whether he was aware that in Egypt one-third of the children of the native population died within 12 months of birth and that another third died before they reached five years of age; and whether he would consider the expediency of suggesting to the Government of Egypt that some inquiry should be made with a view to arrest this heavy infant mortality.—Earl PERCY answered: No, Sir, we have no such information.

An Irish Bishop and the Care of Lunatics.

Mr. SLOAN asked the Chief Secretary for Ireland whether he was aware that Dr. Kelly, Roman Catholic Bishop of Cloyne, had been permitted by the Lord Lieutenant, and contrary to the advice and remonstrance of the inspectors of lunatic asylums, to detach 350 lunatics from the County Asylum in Cork and to lodge them in an unused industrial school at Youghal, which he had prepared for this purpose, that the bishop received a capitation grant for each patient, that there was no resident medical officer to take charge of these patients nor any qualified nurses in charge of them, that the house built and arranged for a medical officer had been handed over to the

committee, of

Mr. TOMKINSON asked the Home Secretary whether his attention had been called to the cases tried in Bedford police court on Feb. 9th last in which fines were imposed for the stealing of cats and in which evidence was given that large consignments of cats had been sent by one of the defendants to a house in

these laboratories informs me that the cats were purchased in the

director) nor anyone else connected
wa
me
the
s which had been received from
ght be inspected by any persons
who had lost cats. If animals are obtained in an improper manner the offenders are amenable to the ordinary law and in the present case a conviction has been obtained.—Sir FREDERICK BANBURY asked the Home Secretary whether his attention had been called to the evidence given in the case at the Bedford police court on Thursday, Feb. 9th, when three men were convicted of cat stealing, to the effect that the animals stolen by these men were consigned to the licensed vivisectors' laboratory at Herne Hill and whether, in these circumstances, he would institute inquiries as to the sources from which animals are generally obtained by vivisectors for the purpose of experiments.—Mr. AKERS DOUGLAS replied: The facts of this matter are given in my answer to the previous question. As I there stated persons who improperly obtain possession of animals can be dealt with by the ordinary law. It would be beyond the functions of the Secretary of State, under the Act 39 & 40 Vict., Cap 77, to institute such general inquiries as are suggested by the honourable baronet, but I am always ready, as in the present instance, to investigate any particular case in which alleged abuses are brought to my notice.

Irish Local Government Board and Maternity Nursing.

nd whether
ent sworn
maternity
l for by a

rty of the

Mr. O'DONNELL also asked the Chief Secretary for Ireland whether he was aware that the Local Government Board had issued a sealed order compelling the Claremorris board of guardians to elect a trained maternity nurse for the Ballyhaunis dispensary district, that the medical officer and other representative men from the district swore there was no necessity for the appointment of such a nurse, that there were two medical men and two trained maternity nurses already practising in that district, and that the evidence of the relieving officer of the district showed there was an average of only three or four applications from the poor each year for assistance; that some of the parties whose names were put to a memorial praying for a nurse had repudiated all knowledge of the matter; and, if so, whether he would give instructions to have the sealed order withdrawn.—Mr. WYNDHAM replied: The evidence of the medical officer at the local inquiry was not to the effect alleged. His evidence clearly showed that no provision existed for the skilled nursing of midwifery cases amongst the poor and that the appointment of a midwife for the purpose was essential. He stated that the births during the past three years averaged 282; that two deaths had occurred in the same

Epidemics in Highland Schools.

in view of the insani-

Board for Scotland, to visit the island in order that a report as to the best mode of dealing with the insanitary conditions might be secured and considered.—The Lord Advocate said: The Local Government Board is prepared to entertain the suggestion made by the hon. Member and will endeavour to arrange for a report to be prepared by one of its staff as soon as his other duties permit.

Recommendations of the Committee on Physical Deterioration.

Sir John Gorst asked the Home Secretary what steps His Majesty's Government was taking to carry out any of the recommendations of the Committee on Physical Deterioration which related to matters within the jurisdiction of his department.—Mr. Akers-Douglas said: I fear I cannot undertake to answer in detail as to those of the committee's proposals in which my department is concerned. Some of these proposals appear to be put forward as suggestions for further consideration rather than as definite recommendations, and I could not take steps to give effect to them without first collecting more information than has been obtained by the committee. Perhaps I may be allowed to say briefly that the committee's recommendations, several of which are engaging my attention, will not be lost sight of. The important subject of defective children, to which the committee refers in recommendation No. 53, is now made the consideration of a Royal Commission.—Dr. Macnamara: May I ask whether it is still the view of the Government that it cannot do anything in favour of the recommendation prohibiting cigarette smoking among children?—The Speaker: Order, order.

Sir John Gorst asked the President of the Local Government Board what steps were being taken to carry out the recommendations in so far as they came within the jurisdiction of his department.—Mr. Long replied: The recommendations made by the committee are very numerous and so far as they relate to matters within the province of my department effect cannot be given to any of them without legislation. A committee which I have appointed, after consultation with the Home Secretary, is inquiring into one important matter referred to by the committee—viz., vagrancy—and I am giving consideration to other subjects referred to in the report so far as I am concerned in them.—Sir John Gorst: May I ask whether one of these subjects is the regulation of the milk-supply?—Mr. Long replied that that was an extremely difficult and involved matter which did not come under his department alone, but it was under consideration.

Sir John Gorst further asked the Secretary to the Board of Education what action he was taking on the report.—Sir William Anson answered: The recommendations which would appear to fall within the existing administrative powers of the Board of Education are recommendations Nos. 17, 18, 20, and 37. The Board had had under its consideration for some time the subjects of these recommendations and had taken, and is taking, steps which it hopes may be of some practical utility on the lines indicated in the report. It is also taking steps, so far as legislation is not involved, to give effect to recommendation No. 35.

Vaccination of School Teachers.

Mr. Weir asked the Lord Advocate whether he was aware that the Scottish Education Department recently declined to allow the Renfrew Landward school board to engage a girl as a pupil teacher on the ground t[illegible] he would explain [illegible] egard to the fact [illegible] t did not indicate [illegible] appointment; and whether he would state why a pupil teacher who had had small-pox was not accepted as eligible for appointment unless successfully vaccinated.—The Lord Advocate answered: It is the fact that the department declined to recognise a girl as a pupil teacher on the ground that she had not been vaccinated. The rule on which this decision was based is a general one imposed in the interests of the health of the children. As regards the last part of the question no case of the kind referred to has yet called for the department's decision

Medical Officers in the Highlands and Islands.

Mr. Weir asked the Lord Advocate whether the Local Government Board had yet considered [illegible] creasing the number of medical officers for [illegible] counties and rearranging the area under their [illegible] Lord Advocate replied: The Local Government Board has long advocated the appointment of a separate medical officer for the islands pertaining to the counties of Inverness and Ross and has reason to believe that the proposal is favourably regarded by the county councils concerned. The views of the Local Government Board regarding the Poor-law medical relief in the Highlands and islands at large are fully set forth in the report of the Board's departmental committee issued a year ago.

Guardians and Medical and Surgical Appliances.

Mr. Sheehy asked the Chief Secretary for Ireland whether he was aware that the Local Government auditor had surcharged three members of the Killadysert union £6 18*s.* 2*d.*, being for medical and surgical appliances; and that the [illegible] Local Government Board; and, [illegible] sustained by the Local Governm[illegible] for [illegible] he facts are correctly stated. Th[illegible] upheld by the Local Government me[illegible] urged represented the cost of me[illegible] er and above the reasonable wa[illegible] payment was excessive and exorbitant.

Tuesday, Feb. 28th.

Underfed Children.

Dr. Macnamara asked the Secretary to the Board of Education whether any local education authorities had either petitioned or forwarded resolutions to the Board of Education in favour of such an extension of their powers as would enable them, out of the funds at their disposal, to provide food for underfed children on the lines suggested in the unanimous recommendation of the Committee on Physical Deterioration (1904).—Sir William Anson replied: The Board [illegible] the lines referred to in the question from [illegible] education authorities: in May, 1904, from [illegible]; in December last from Sheffield county orough; and in January last from Tottenham urban district.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Addison, William B., M.B., B.C., M.R.C.S., L.R.C.P. Lond., has been appointed a Medical Referee under the Workmen's Compensation Acts, 1897 and 1900, and to act for Croydon and Epsom County Courts in County Court Circuit No. 45.

Aldous, G. F., F.R.C.S. Edin., has been appointed Assistant Surgeon to the East Cornwall Hospital, Plymouth.

Blackburn, C. B., M.D. Syd., has been appointed Honorary Pathologist to the Royal Alexandra Hospital for Sick Children, New South Wales.

Bradley, J., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Gortin District of the county of Tyrone.

Broadbent, P. L., M.B. Syd., has been appointed Junior Medical Officer in the Lunacy Department, New South Wales.

Cooper, H. W., M.D., has been appointed Government Medical Officer and Vaccinator at Wyong, New South Wales.

Fox, E. L., M.D. Cantab., has been appointed Physician to the East Cornwall Hospital, Plymouth.

Graham, A. W., M.B. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Port Health Officer at Beauty Point, Tasmania.

Gruner, O. C., M.B. Lond., has been appointed Honorary Pathologist to the Leeds Public Dispensary.

Killick, C. R., M.B. Lond., L.S.A., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Williton District of the county of Somerset.

Lucy, R. H., M.B., C.M. Edin., has been appointed Surgeon to the East Cornwall Hospital, Plymouth.

Morrice, George Gavin, M.A., M.D. Cantab., M.R.C.P., has been appointed Honorary Physician to the Dorset County Hospital.

Myles, Thomas William, B.A., M.B., B.Ch. Irel., R.N., has been appointed temporarily Surgeon to the Plymouth Division of Royal Marines.

Pardey, J. M., M.B., Ch.B., has been appointed Honorary Medical Officer to the Launceston Hospital, Tasmania.

Patterson, D. Wells, M.B., B.S. Durh., has been appointed Honorary Physician to the Hospital for Diseases of the Skin, Newcastle-on-Tyne.

Pope, G. Stevens, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Superintendent of the Somerset and Bath County Asylum, Wells, Somerset.

Prendergast, J. J., M.D. Dub., has been appointed Local Health Officer at Strahan, Tasmania.

Rendle, C. E. Russell, L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Surgeon to the East Cornwall Hospital, Plymouth.

Smith, E. G., M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to Out-patients at the East Cornwall Hospital, Plymouth.

Soltau, Bertram, M.D. Lond., has been appointed Physician to the East Cornwall Hospital, Plymouth.

Webber, H. W., F.R.C.S. Edin., has been appointed Assistant Surgeon to the East Cornwall Hospital, Plymouth.

Whiteford, C. Hamilton, M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to In-patients at the East Cornwall Hospital, Plymouth.

Whiteford, W. Crosbie, has been appointed Anæsthetist to In-patients at the East Cornwall Hospital, Plymouth.

Whipple, C., L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the East Cornwall Hospital, Plymouth.

Wilmott, Robert, F.R.C.S. Edin., has been appointed Official Visitor to the Hospital for the Insane, Launceston and New Norfolk, Tasmania.

Woollcombe, W. L., L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the East Cornwall Hospital, Plymouth.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birkenhead Borough Hospital.—Assistant Honorary Medical Officer.

Birkenhead Union, Infirmary, Workhouse, and Sanatorium.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

Bradford Children's Hospital.—House Surgeon. Salary £100.

Brighton Throat and Ear Hospital, Church-street, Queen's road.—Non-Resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

Bristol Royal Infirmary.—Honorary Physician.

Carlisle, Cumberland Infirmary.—Resident Medical Officer. Salary at rate of £80 per annum, with board, lodging, and washing.

Cheltenham General Hospital.—Junior House Surgeon, unmarried. Salary £50 per annum, with board and lodging. Also Surgeon-in-Charge (unmarried) of Branch Dispensary. Salary £90 per annum, with board and lodging.

Notes, Short Comments, and Answers to Correspondents.

HARVEY AND FINCH: A REMARKABLE MS.

IT will no doubt interest most of our readers to know that Messrs. Sotheby, Wilkinson, and Hodge, will include in a sale at their rooms on March 4th a folio MS. Common-Place Book, in the original calf binding, of the celebrated lawyer, Heneage Finch, afterwards Earl of Nottingham and Lord Chancellor, which contains two pages with long and curious medical directions in the autograph of his far more illustrious uncle and physician, Dr. William Harvey, written in 1647, when Harvey was aged 69 and Finch 26 years. As the sale catalogue states, "Even the signature of this great anatomist is of the utmost rarity. *Nowhere else outside the British Museum can so much of his handwriting be found as in the present MS.*, which came from Miss Finch of Maidstone at her death some 40 years ago." The well-known antiquary and Harveian scholar, Mr. W. J. Harvey, has examined the MS. and added several interesting particulars, stating that probably the medical directions alluded to above were for the relief of rheumatism, from which it is not generally known that Finch suffered in his younger years. Mr. Harvey has discovered [illegible] death), mentioning *inter alia*, "Our present Lord Chancellor was for many years in his younger days much grieved with a rheumatism, and never could get a cure for it until he followed the advice of his brother, Sir John Finch, and Dr. Baines, both newly returned from Italy, which was to drink three pints of Bordeaux claret every day. If you should object to me, my Lord Chancellor's gout and stone, I can answer that neither of these seized him till many years after his use of wine, and may very justly be attributed to his much setting." The interest and the importance of the MS. Common-Place Book are, however, vastly increased by the remarkable anticipation of the electric telegraph and wireless telegraphy which it contains on p. 467.

AN IMPROVED HAMMOCK FOR INVALID RAILWAY TRAVELLERS.

To the Editors of THE LANCET.

SIRS,—May I add my testimony to the value of the improved hammock for invalids travelling? I [illegible] King's Cross to Cambridge and back [illegible] journey I was in the hammock and [illegible] restful and comfortable. We travelle [illegible] test more severe were at the end of the train. There was absolutely no lateral swaying, no jarring, and vibration was reduced to a minimum so as to be scarcely perceptible. The only movement was a rocking from head to feet whilst passing over points or round sharp curves, and [illegible] hern Railway inspector [illegible] It is much to be hoped [illegible] railway companies and [illegible] neans to travel in ease and comfort.

I am, Sirs, yours faithfully,

THE MOTHER OF AN INVALID.

Feb. 25th, 1905.

SUPERFLUOUS HAIRS.

M.B., having read Dr. Balmanno Squire's article on enelectrolysis which we published last week, asks for further advice from our readers in the treatment of superfluous hairs occurring on the chin, putting the following questions: Has treatment by the x rays any advantage over electrolysis? Is either a permanent cure? Is there any scarring where the x rays are used? Do the x rays inhibit a further accumulation of new hairs or do they only destroy those already existing?

THE REMOVAL OF BODIES.

[illegible] ambulance should have been requisitioned, which would have been preposterous. Ambulances are intended and used for conveying patients to the hospitals and it would not tend to make them popular vehicles for that purpose if it were known that they were also used for carrying dead bodies. The charge of brutality seems unfounded. A stretcher was taken into the house, the body was placed upon it, covered up, and carried away on the "hand ambulance," as it is called—that is, the framework with wheels on which the stretcher is placed. No doubt the method might be improved on. It is not a pleasant spectacle to see this gruesome carriage with its dead or injured burden wheeled along the street, but at present there seems no way of avoiding it. The coroner said that personally he should like bodies removed in an undertaker's van but he had no power to order it. In connexion with this case the chief constable reported to the watch committee that every consideration was shown to the relatives and every possible respect paid to the body. If the committee provided a special van the police would use it for the purpose. It may be hoped that this concession to a widespread and instinctive feeling may be made.

INCURABLE PATIENTS.

To the Editors of THE LANCET.

SIRS,—May I inquire through your columns if any of your readers know of an institution which takes in incurable patients *on payment?*

I am, Sirs, yours faithfully,

JOHN GAY.

137, Upper Richmond-road, Putney, S.W., Feb. 21st, 1905.

SOME QUESTIONS WITH REGARD TO MILK-SUPPLY.

To the Editors of THE LANCET.

SIRS,—1. Supposing pastures are manured by human excrement from pails or middens or with farmyard manure early in April and cows are turned out to graze on the same pastures in May, can the milk obtained from these cows be pure and wholesome? I have noticed a large mortality amongst lambs on such pastures.

2. Suppose milking-cows have for their only drink in the long hot summer days water from stagnant pools—say a pool 20 feet in diameter and two feet deep for a dozen cows—beautifully iridescent on the surface, which also reveals the distended bellies of dead pups and kittens, the cows stand in the pool and further pollute it, can the milk obtained from these cows be pure and wholesome? I am told that this is "all right, cows prefer such water." It appears to me that unless the milk is pure as it comes from the cow's udder no subsequent processes to which it may be subjected can make it into a wholesome "food."

I am, Sirs, yours faithfully,

Feb. 26th, 1905. C. C.

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to acknowledge the receipt of the following additional contributions?

I am, Sirs, yours faithfully,

ALEXR. P. FIDDIAN, Treasurer.

23, The Walk, Cardiff, Feb. 28th, 1905.

Nemo.—1. If the person responsible for the payment has given the patient into Dr. B's charge and if the patient's parents have not signified to Dr. B any desire that their child should be in other hands we think it will be difficult to formulate any charge of unprofessional behaviour against Dr. B. 2. This question is practically answered above, but if Dr. B has heard from Dr. A that the child's parents do desire, despite their silence, that he should be attended by their medical man—viz., Dr. A—we think that Dr. B might well associate Dr. A with him in the case.

Amicus.—It appears that B and C having their headquarters quite near each other have now, each of them, got a branch or agency centre at the other's door. We do not in those circumstances think either can be said to have a grievance against the other, but if a sense of wrong exists it would be better that they should refer the matter to a common friend, agreeing to abide by his decision. The situation is one upon which professional colleagues should not quarrel.

G. T. W.—We agree with our correspondent that his dismissal by postcard was discourteous but it must not be assumed that all postcards are read at the post-office and discussed afterwards by the public or that the medical man designed any injury.

Sufferer.—We are unable to find our correspondent's name in the Medical Directory, so that he will not be surprised to find that we are unable to publish what amounts to a serious charge against one of his teachers whom, by the way, he does not specify.

D.P.H.—(A) We know of no convalescent homes exactly of the sort that our correspondent wants where such small payments would be taken. (B) There would be no harm in returning the circulars in the way suggested.

Disgusted.—We cannot subscribe to the doctrine that if B goes back on his word A is entitled to do the same. A should keep his promise despite the absence of a stamped agreement.

Visitor can obtain the information that he seeks from Dr. Dawson Williams, 2, Agar-street, Strand, London, or Dr. W. Jobson Horne, 27, New Cavendish-street, Portland-place.

M.R.C.S.—The treatment is rubbish.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.).

TUESDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Royal Ear (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.).

WEDNESDAY (8th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.) Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.).

THURSDAY (9th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M., [illegible] North-West London (2 P.M.), Gt. Northern [illegible] Metropolitan (2.30 P.M.), Lond[illegible] (2 P.M.), Samaritan (9.30 A.M. an[illegible] (9.30 A.M.), Guy's (1.30 P.M.).

FRIDAY (1[illegible] St. Bartholomew's (1.30 P.M.), St. Thomas's [illegible] Cross (3 [illegible] (2 P.M.), [illegible] Northern Central (2.30 P.M.), West London [illegible] Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Royal Ear (10 A.M.).

SATURDAY (11th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (6th).—MEDICAL SOCIETY OF LONDON (11, Chandos street, Cavendish-square, W.).—9 P.M. Dr. G. H. Savage: Mental Disorders of Decay. (Lettsomian Lecture.)

TUESDAY (7th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—Prof. W. D. Halliburton: Recent Researches on Proteid Chemistry and Proteid Diet.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—5 P.M. Adjourned Discussion on the Subsequent Course and Later History of Cases of Appendicitis after Operation (opened by the President, Sir R. Douglas Powell). Dr. Hawkins, Mr. Lockwood, Mr. Battle, Sir William Bennett, Mr. Mayo Robson, and *others will take part in the discussion.*

WEDNESDAY (8th).—BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Discussion on the Ethics of Health Resort Treatment (opened by Dr. L. Williams).

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Demonstration of Cases of Interest.

HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Pathological Evening. Exhibition of Specimens.

THURSDAY (9th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Dr. F. Edge. Paper:—Dr. I. Parsons: The Choice of Treatment for Fibromyoma of the Uterus.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Mr. M. Morris: Some Modern Therapeutic Methods in Dermatology, with Cases treated by the *Roentgen and Finsen Rays.* (Harveian Lecture.)

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-square, W.).—8 P.M. Clinical Meeting. Cases will be shown by Mr. E. Chatterton, Mr. C. Blair, Mr. A. Ogilvy, Mr. J. H. Parsons and Mr. A. Lawson, Mr. J. H. Parsons, Mr. R. E. Bickerton, and Mr. H. McMullen.

FRIDAY (10th).—THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi-terrace, Strand, W.C.).—7.30 P.M. Discussion of the Causes of the Increased Prevalence of Anthrax in Great Britain (opened by a paper read by Prof. S. Delépine).

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.15 P.M. Mr. J. Berry will exhibit a Case showing the Result of a Rhinoplastic Operation; a paper will be read at a subsequent meeting. 8 30 P.M. Papers:—Dr. W. H. White: A Case of Acute Rheumatoid Arthritis (with epidiascope demonstration).—Dr. B. Abrahams: Arthritis Deformans and its Allies.—Mr. D. Drew: Three Cases of Stenosis of the Ureter.

BR[illegible] GICAL ASSO- [illegible] Cavendish- [illegible] Nourse, Dr. [illegible] Lodge, Mr. [illegible] S. Wallace's [illegible]

SAMARITAN FREE HOSPITAL FOR WOMEN (Marylebone road, N.W.).—3 P.M. [illegible]

THE HO[illegible] W.C.).—4 P.M. [illegible]

FRIDAY [illegible] POLYCLINIC (22, C[illegible] Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.) 5 P.M. Dr. Abraham: Cases of Skin Disease.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Mr. M. Gunn: Optic Atrophy.

NORTH-EAST LONDON POST GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Lecture:—Dr. R. M. Leslie: Prognosis in Acute Pulmonary Affections.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

The Erasmus Wilson Lectures

ON

PERITONITIS, A BACTERIOLOGICAL STUDY.

Delivered before the Royal College of Surgeons of England on Feb 20th 22nd, and 24th 1905,

BY LEONARD S DUDGEON, M R C P LOND, M R C S ENG,

SUPERINTENDENT OF THE CLINICAL LABORATORY AND DEMONSTRATOR OF CLINICAL PATHOLOGY AT ST THOMAS S HOSPITAL GILLSON SCHOLAR IN PATHOLOGY OF THE SOCIETY OF APOTHECARIES ERASMUS WILSON LECTURER ROYAL COLLEGE OF SURGEONS OF ENGLAND

AND

PERCY W G SARGENT, M A, M B, B C CANTAB, F R C S ENG,

RESIDENT ASSISTANT SURGEON AT ST THOMAS S HOSPITAL ERASMUS WILSON LECTURER ROYAL COLLEGE OF SURGEONS OF ENGLAND

LECTURE III[1]

Delivered on Feb 24th

THE FUNCTIONS OF THE PERITONEUM

MR PRESIDENT AND GENTLEMEN,—It is customary to regard the peritoneum as a vast lymphatic space of great absorptive power Whatever may be the extent to which this power is exercised in the normal state it is certain that, under abnormal conditions, the peritoneum is capable of absorbing large quantities of fluid That which is left in the peritoneal cavity after copious flushing and closure of the abdomen is transferred to the circulation with such rapidity as to be credited with a therapeutic action of the same nature as an intravenous infusion a theory which receives support from the observation that if such a case proves fatal there is at the necropsy practically no fluid remaining even when the patient has survived the operation only a few hours Wegner found that a dog s peritoneum is capable of absorbing in one hour an amount of fluid equal to from 3 to 8 per cent of the animal s body weight Dubar and Remy found the thoracic duct of a rabbit greatly distended in as short a time as five minutes after a large intraperitoneal injection of albuminous fluid The greater the percentage of albumin, however, the less rapidly was the absorption effected

This power of absorption is one of the factors to which the comparative safety of abdominal operations is largely due, for various fluids, even in large quantity, which at times soil the peritoneum during an operation can be safely disposed of The peritoneum in fact to expand a trite expression, performs its own toilet This function however can only be exercised within certain limits and it is to the factors lying beyond these limits that we must look for an explanation of many of the phenomena of peritonitis It is important in the first place to understand in what manner and by what channels this absorption is effected The normal peritoneum is, save for the exception of the Fallopian tube in the female a closed sac, closed microscopically as well as macroscopically It is no longer held that the cavity communicates directly with the lymphatic system Muscatello has shown the picturesque stomata of the older writers to have no greater significance than errors of histological technique His researches showed that not only are there no stomata between the endothelial cells but that there are not even any subendothelial lymphatic spaces over by far the greater part of the serous membrane of the abdominal cavity The lymph spaces which underlie the endothelial covering of the diaphragmatic peritoneum are absent from that which is disposed over the viscera and abdominal wall His experiments with carmine upon the peritoneal cavities of dogs showed that the diaphragmatic is the only part of the peritoneum where solid particles are absorbed into the lymphatics and that there is normally a lymph flow towards the diaphragm independent of, but influenced in point of time by, gravity

The structure of the diaphragmatic peritoneum is completely different from that of the rest of the serous membrane It presents innumerable pits or wells, perpendicular

Muscatello observed coloured particles taken up first into these intertendinous pits and then into the lymphatics This transfer is carried out entirely by means of phagocytes and is accomplished with extraordinary rapidity, for Dubar and Remy found particles of carmine in the thoracic duct only seven minutes after intraperitoneal injection The irritation of the peritoneum with foreign substances is the signal for the entrance of numbers of phagocytic cells in a clear fluid exudate, the number being proportionate partly to the time which has elapsed, but chiefly to the nature of the substance which has called them upon the scene Sections of the diaphragm in cases of peritonitis show the lymphatic spaces crowded with leucocytes laden with bacteria

Whatever absorption cannot take place by the lymphatic channel must do so by means of the blood stream directly and it is this which constitutes one of the greatest perils of peritonitis It is questionable whether the healthy peritoneum allows the absorption of anything but fluids to take place by this means but damage to the protective endothelial covering will render it possible Provided that this endothelium is uninjured, bacteria and other foreign substances will within limits be safely disposed of by the lymphatic route, but damage will at once permit absorption to take place by the vascular route Indeed, a parallel exists between the peritoneum and the skin The uninjured hand may be soaked with virulent material with impunity, but an abrasion may determine a rapid and even fatal absorption The extreme delicacy of the peritoneal membrane, in its thickest part not more than 120μ in depth, renders it particularly susceptible to injury and we have evidence to show that some at any rate of the fatal cases of peritonitis are due to a true septicæmia In cases of peritoneal infection, however, the patient s safety does not depend solely upon the integrity of the endothelium The most rapidly fatal organism in peritonitis in the human subject is the streptococcus pyogenes In cases dead of this infection there is observed an entire absence of agglutination of the intestinal coils a phenomenon which is early observed in the case of an infection to which the peritoneum reacts and this fact goes hand in hand with the differing behaviour of the leucocytes in the two

to a fibrinous deposit upon

that, as a rule the longer

ter is the amount of fibrin

deposited upon the peritoneum

Sections of intestine from a case of gastric perforation operated upon 16 hours after the onset which proved fatal from shock almost immediately after the operation but with very little naked eye evidence of peritonitis show the endothelial layer intact and covered with a microscopic deposit of fibrin in the meshes of which are entangled, innumerable leucocytes There is also seen a round celled infiltration of the subendothelial tissues which, however becomes less as the lumen is approached, whilst the mucous membrane is unaffected At this stage then the endothelial layer is as it were sandwiched between the fibrinous deposit and the underlying area of round celled infiltration Turning now to the diaphragm in a case of peritonitis from appendicitis of five days duration which proved fatal almost immediately after a limited operation we see this deposit very much more marked the subendothelial infiltration more intense and the endothelial layer itself indistinguishable A more advanced instance still is that of a case of chronic suppurative peritonitis which proved fatal seven weeks after the opening of an appendix abscess Here there are enormous thickening of the peritoneum degeneration of the underlying muscle and disappearance of the endothelial layer The deeper layers of the deposit are organised into fibrous tissue and as the cœlomic surface is approached this tissue is less and less perfectly organised until at the surface itself we come to the amorphous fibrinous deposit which is seen in the other cases

We conclude that this fibrinous deposit serves a protective function both limiting the absorption of toxic material into the subperitoneal blood vessels and at the same time preventing the further egress of organisms from the intestine into the peritoneum The absence of this deposit from the most acute cases of all allows a fatal issue to occur from hæmic absorption. Another way in which this fibrinous deposit serves as a protective measure is by the agglutination of intestinal coils whereby a localisation of infection may be brought about.

---

[1] Lectures I and II were published in THE LANCET of Feb 25th (p 473) and March 4th (p 540) 1905 respectively

If the peritoneal infection subsides before the endothelium is irrevocably destroyed then the fibrin will be absorbed and the peritoneum resumes its normal appearances, although in consequence of the subendothelial infiltration it will remain permanently thickened. This explains the almost miraculous disappearance of adhesions which is the wonder of the surgeon when he comes to reopen the abdomen some months after the occurrence of an intraperitoneal abscess. The permanent thickening explains, in part at any rate, the resistance to infection which is conferred upon the peritoneum after a previous inflammation. If, however, the endothelium has been destroyed and the fibrinous deposit has had time to organise, then persistent adhesions must result. It will be seen that the pulling off of fibrinous plaques at an operation is to be deprecated as it lays bare the subperitoneal vessels for absorption and that any rough handling which damages the endothelium is likely to be rewarded by the formation of persistent adhesions. It will also be seen that the thorough cleansing of the peritoneum by washing is not only, as is shown in another place, undesirable but a physical impossibility.

What happens when micro-organisms are introduced into the peritoneal cavity depends upon the virulence of those organisms and their power of so damaging the endothelial covering as to gain access to the subendothelial tissues, upon the power of the individual to produce a leucocytosis, and upon the ability of the phagocytes so produced to deal with the organisms. We believe the virulence of the organisms and the rapidity with which they are introduced to be of greater importance than the actual dosage. It is notorious that in many pelvic operations large quantities of purulent fluid may escape into the peritoneal cavity with impunity; the explanation lies in the extremely low degree of virulence of the organisms commonly met with in gynæcological work. Again, peritoneum soiled as it must be with intestinal contents during anastomotic operations under healthy conditions rarely becomes the seat of a spreading inflammation of any consequence, but similar operations undertaken during intestinal obstruction, when the virulence of the intestinal organisms is exalted, are attended with a much greater risk.

We have thought it advisable to eliminate the term "general" as applied to peritonitis, since it is used loosely in two very different senses. By some the term is used to signify that the inflammatory process involves the whole peritoneal surface and by others that it is unlimited by obvious adhesions and is in the process of spreading after the fashion of a cutaneous erysipelas. For the former meaning we have adopted the name *universal* and for the latter *diffuse*—a term which implies no expression of opinion as to the extent of the infection but merely that it is unlimited by definite adhesions. By adhesions we mean every stage from the mere agglutination of neighbouring peritoneal areas to definitely organised tissue.

From the appearances seen at operation it is impossible to form an opinion of any value as to the extent of the peritonitis present. It is customary to gauge it by the degree of redness and distension and by the naked eye appearance of the exudate but we are convinced that none of these criteria are trustworthy. J. W. Crile has shown that the stimulus supplied by opening the abdomen and manipulating the intestines is sufficient to produce a rapid dilatation of the vessels of the splanchnic area. If one watches a given coil of intestine during an abdominal operation one is struck with the rapidity with which the appearance alters. A coil which, on opening the abdomen, appears flabby and slate-coloured or quite pale, on exposure and manipulation takes on first a general flush and soon afterwards one can see the subperitoneal vessels mapped out in a pattern. At the same time the lumen appears to fill with gas and to become distended. If the operation is prolonged or the manipulation is at all violent the changes are such that an observer seeing it for the first time would pronounce some degree of peritonitis to be present. These changes occur much more rapidly in conditions of obstruction or peritonitis, so that at the end of the operation the peritonitis appears to be more severe in degree and extent than at the beginning. To estimate the peritonitis present, then, even by the usual criteria, the observation must be made immediately the abdomen is opened. Now if, as Crile holds, shock is due to reflex vaso dilatation of the splanchnic area then such a condition as the crushing of a limb will be accompanied unseen by an increased vascularity of the intestines. Shock from the sudden strangulation of a hernia or the perforation of a gastric ulcer will be accompanied by similar changes so that on opening the abdomen a more extensive degree of peritonitis will appear to be present than is actually the case when tested by bacteriological means.

Many experimenters have shown that the natural resistance of the peritoneum to infection can be artificially increased. Issaeff in 1894 was the first to show that various sterile solutions previously injected into the peritoneal cavity of guinea-pigs could render that membrane more or less refractory to infection with certain pathogenic organisms. In the following year Melsome and Cobbett, working with cultures of streptococci, showed that an immunity could be produced by successive minute inoculations. H. E. Durham obtained similar results in rabbits from preliminary injection of sterile fluids. More recently, Salieri, and Miyake working under Professor von Mikulicz, have confirmed these observations and succeeded in producing an artificial immunity in animals by preliminary intraperitoneal injections of sterile saline solution, nucleic acid, and other substances. The protection thus afforded is, as Durham pointed out, due in large measure at any rate to the appearance in the peritoneal exudate of certain phagocytic cells. The question arises whether this artificial protection has any counterpart in the natural events of peritonitis. We believe our observations to show that it has.

We can draw no hard and fast line between intestinal obstruction and peritonitis. Every case of obstruction may be regarded as an early stage of peritonitis, for to that end it will undoubtedly come if unrelieved, either by perforation or the wandering of organisms through the damaged intestinal wall. Similarly a quantity of blood or other sterile fluid, too large to be safely disposed of by absorption or encapsulation, will sooner or later be the cause of peritonitis, the organisms arriving we do not know exactly how, but in all probability from the intestine thus irritated by its presence. We have been struck with the extreme ease with which organisms do make their way into the peritoneal cavity in many abnormal conditions, even in the early stages of congestion in many cases of obstruction. The organism which, as we have shown in a very large number of cases, usually is the first to make its appearance in the peritoneal cavity is the staphylococcus albus. We have found it in almost every variety of peritoneal lesion which has come under our notice. As a general rule it is to be found on the peritoneal surface at a distance from the focus of most severe disturbance and in association with numbers of phagocytes. It is an organism of very low virulence. Present in many cases of intestinal obstruction and of strangulated hernia it does not produce, when once the obstruction has been relieved, fatal peritonitis and rarely suppuration of the parietal wound; present beyond the area of acute infection in cases of appendicitis it produces no spreading peritonitis when the abscess has been opened or the appendix removed; present invariably in the bloody exudate of ruptured tubal pregnancy it produces in most cases nothing more than a febrile disturbance of little moment. In guinea-pigs it can be inoculated intraperitoneally without fatal effect. The effect which, as we have seen, it does produce is to determine the advent of numbers of phagocytic cells. Again, in cases of spreading peritonitis the outlook is better when this organism is found beyond the area of most intense infection in a remote region of the peritoneal cavity.

All these facts lead us to the conclusion that the staphylococcus albus exercises some sort of protective action in peritonitis and that by determining the advent of phagocytes. It, therefore, in nature, takes the place of those chemical substances which have been found by Miyake and others to be capable of producing an artificial immunity. How or why this staphylococcus appears upon the scene we do not know and we are unable even to hazard a guess.

Having arrived, however, it seems to provoke the appearance of a clear fluid exudate which soon becomes turbid from the presence of innumerable phagocytic cells and the more turbid it becomes the more it appears to the surgeon as something to be washed away. Later the more virulent organism, in the majority of cases the colon bacillus, appears, and it is upon the start, so to speak, which the staphylococcus has had, and the ability of the individual to respond to the call, that the prognosis to a large extent *depends, provided that the natural safeguard is not interfered* with by violent treatment Generally speaking, we conclude that if in a case of peritonitis the staphylococcus albus is found alone in a remote region of the peritoneum the outlook is much better than if it is found in association with the colon bacillus, and that if the colon bacillus is found alone in this remote region the patient will die

As the staphylococcus albus is usually the first to appear, so it is the last to disappear when the individual has overcome the infection, for it has been found to persist in some cases in the peritoneal cavity long after the other organisms have vanished This may serve to explain the comparative rarity with which acute infective appendicitis occurs if there have been previous attacks By far the largest number of the so called fulminating cases of appendicitis are first attacks

There is a second way in which the staphylococcus albus [illegible] protective action and that is by

In many cases cultures

[illegible] itoneal adhesions, in the stage when they exist only as coagulated fibrinous exudate, show this organism to be present A good instance of this, in our series, was a case of dysenteric hepatic abscess with adhesion formation From what we have stated the question naturally arises whether it is possible to form an opinion as to the probable course of a case of peritonitis from an examination of the exudate Culture methods, from the time consumed, would be of little value, although the colon bacillus can be identified in as short a time as three hours from broth cultures incubated at 37° C , but we believe that it is possible to make a prognosis from the microscopical examination of films taken from a remote region of the peritoneum If phagocytic cells are abundant and if cocci, other than streptococci, are present the prognosis should be favourable If *bacilli also are present, but if cells are* abundant and cocci predominate, the outlook is more grave but not necessarily hopeless But if cells are scanty and disintegrated and bacilli are alone or predominate, or if streptococci are present, then the case may be regarded as hopeless

As a result of our observations we have been led to formulate a theory which appears to us to explain many of the phenomena of peritonitis In every class of case we have found the staphylococcus albus to be the first organism to appear in the peritoneal cavity and it is only reasonable to assume that it makes its way out, if, indeed, it does come from the intestine at the point of most severe damage But where the damaged intestine is of large extent, as in a volvulus, for example, we find that organism distributed indiscriminately over a very [illegible]

followed at a later period, if the obstruction is unrelieved, by other organisms, notably the colon bacillus Similarly, in peritonitis of intestinal origin due to causes other than obstruction we believe that organisms make their way out, not only at the primary focus but also from each successive portion of intestine as it becomes inflamed and distended If this is so then several of the phenomena of peritonitis are accounted for which otherwise it is difficult to explain First, it accounts for the rapidity with which a vast area of peritoneal surface becomes involved and that in spite of any paralysis which may be present Secondly, that the stimulus for the advent of enormous masses of phagocytes is rapidly applied over a large area Thirdly, that the staphylococcus albus is so frequently found in advance of the other organisms present Fourthly, that we so frequently find organisms on the surface of the gut but not always, in the same cases in the exudate They are practically never found in the exudate when they are not present on the gut surface This is an observation which has been made by other observers, notably Durham, who attributed it to the deposition of organisms from the exudate upon the peritoneum in much the same manner that organisms tend to settle to the bottom of a culture tube in which they are growing Lastly, this view explains how it is that in a subsiding peritonitis residual abscesses may be formed in any situation and without any direct connexion with the original focus of infection

PERITONITIS ARISING FROM INFLAMMATORY DISEASES OF THE FEMALE PELVIC ORGANS

No instance of puerperal peritonitis has come under our notice but we may accept the statement which has been *made by a large number of observers that such cases are of* streptococcic origin, and, indeed, clinically they resemble the examples of streptococcic peritonitis arising from other causes which we have examined The peritonitis which arises from a pyosalpinx is of quite a different character and neither the clinical course nor the bacteriological findings in our cases support the view that the inflammatory condition in salpingitis favours the development of pyogenic organisms other than the gonococcus and that it is these organisms which give rise to the peritonitis

The causal relation of the gonococcus to peritonitis is one which, although difficult of *proof, may be* considered to have been definitely established Wertheim as long ago as 1891 showed that the gonococcus could produce a localised peritonitis in animals He recovered this organism in pure culture from the seropurulent exudate Kelly, in 1898, however, stated that in many hundreds of bacteriological examinations he had never been able to demonstrate the gonococcus as the etiological factor in the production of septic peritonitis In one of his cases he writes "A pyosalpinx had ruptured some days before the operation and pus containing myriads of gonococci lay free in the pelvis but there was no peritonitis ' In the following year, however, Cushing published two cases of gonorrhœal peritonitis which were operated upon and recovered In both of these gonococci were demonstrated in films of the peritoneal exudate and from one he grew the gonococcus No other organisms were found Hugh Young has succeeded in cultivating the gonococcus upon the same medium from cases of gonorrhœal peritonitis The bacteriological evidence afforded by the few cases in which the organism has been demonstrated definitely by culture methods is supported by many others in which Gram negative intracellular *diplococci have been found in films of the peritoneal* exudate but where cultures have remained sterile, and by others, again, of a definite peritonitis dependent upon salpingitis in which no organisms have been demonstrated, for these cases go at any rate to show that such a peritonitis is not dependent upon any of the easily cultivated pyogenic organisms

In five out of eight cases examined cultures from the peritoneal exudate and from the interior of the tubes were found to be sterile although numerous culture media were employed—namely broth, agar and blood agar, and glucose broth for anaerobic cultures In one case, however, large numbers of diplococci, chiefly intracellular, were found in film preparations from the peritoneal exudate and also from the interior of the Fallopian tube The organism failed to retain Gram s stain, although the morphological characters of the coccus were not absolutely typical of the gonococcus It is most probable however, that the organism was the gonococcus, although we failed to cultivate it This is the only case in which probable gonococci were found In one case we isolated the staphylococcus albus from a localised intraperitoneal abscess connected with a left pyosalpinx In the other cases we failed to cultivate any micro organism *from* either the peritoneal exudate or from the interior of the tubes This is of interest owing to the recent views which we have already referred to—namely, that salpingitis is frequently due to the common pyogenic cocci

We have four examples of diffuse peritonitis spreading from a pyosalpinx The onset was sudden but the progress of the symptoms was not very acute, the interval between onset and operation being 5 10, 14 and 20 days respectively In two the pulse rate was 120 before operation, with elevation of the temperature to 102° F. ; in the other two the temperature was only slightly above the normal and the pulse was not *accelerated . In all there was an odourless* peritoneal exudate, clear in three slightly turbid in one, and in each instance it was distinctly viscid The peritoneum was reddened in the neighbourhood of the uterine appendages but there was no intestinal distension—a point of interest in view of the fact that no organism could be cultivated from the exudate In two of these cases intracellular diplococci were seen in the film preparations but all remained sterile to cultivation whatever medium was employed The treatment was the same in each instance—namely, removal of the Fallopian tube, lavage of the pelvis with sterile saline solution, and drainage—and all the patients recovered We consider *these four cases to be* examples of diffuse gonorrhœal peritonitis

We conclude that the gonococcus causes a peritonitis which may be diffuse or localised; that it possesses a very slight degree of pathogenicity when introduced into the peritoneal cavity; that although the onset may be sudden the subsequent symptoms are those of a very low form of peritonitis; that intestinal distension is usually absent; and that the prognosis is very favourable. We believe the relatively low rate of mortality in these cases to be due not to any special properties of the pelvic peritoneum, but to the low degree of virulence possessed by the organisms present in the Fallopian tubes. Andrews, in 1904, published the results of bacteriological examinations of the interior of the tube in 684 collected cases of pyosalpinx. The diagnosis in most instances was based upon microscopy only; in some upon both films and cultures and in a few upon animal experiments. The result showed 5 per cent. to be sterile, 22·5 per cent. to contain the gonococcus, 6 per cent. saprophytes only, and the rest a variety of pyogenic organisms. It is true that these figures are based largely upon very incomplete bacteriological examinations and must therefore be received with a good deal of reserve but they go to show what a small proportion of cases of pyosalpinx constitute any grave danger to the peritoneum.

Peritonitis arising from suppurating ovarian cysts.—Of these we have examined three cases. In two the lethal organism proved to be the colon bacillus; in the third the streptococcus pyogenes. These three cases present several points of interest. In the first place the colon bacillus may be the cause of a fatal peritonitis arising from a lesion wholly unconnected with the intestinal tract. In one example it was already present in the peritoneal cavity at a distance from the original lesion when the operation was undertaken; in the other there was no diffuse peritonitis at the time of operation, but doubtless the colon bacillus, liberated by opening the abscess, infected the peritoneum. The third case was one of streptococcus infection of an ovarian cyst and the resulting peritonitis followed the usual course of a streptococcic peritonitis. In the two cases in which the peritonitis was diffuse at the time of operation the staphylococcus albus was present in a part of the peritoneal cavity remote from the point of most intense inflammation, and here the intestines were distended. In this respect these cases are strictly comparable to many of the cases of peritonitis arising from other lesions, notably from disease of the vermiform appendix.

INTESTINAL OBSTRUCTION

The simplest form of peritonitis arising in connexion with the bowel is that which results from the early stages of intestinal obstruction. We have studied 100 cases of intestinal obstruction from the bacteriological point of view and have found micro-organisms present in 48 instances. The 47 cases of strangulated hernia which are included in this series will be considered separately because the mechanical conditions present render it impossible to ascertain the condition of the peritoneum at a distance from the site of the obstruction. It has long been known that the fluid in the sac of a strangulated hernia may contain micro-organisms.

[Previous observers—namely, Nepveau, 1867; Garré, 1886; Clado, 1889; Bönnecken, 1890; Tavel and Lanz, 1893; and Rodella, 1903—were here referred to.]

Our tables include 47 cases of strangulated hernia. Cover-slip preparations were made of the fluid in the hernial sac in 33 of these cases, in 31 of which no micro-organisms were seen, but in one case Gram-positive cocci and Gram-negative bacilli and in the other Gram-positive cocci only were found. In 42 cases the fluid in the hernial sac was found to be sterile. In five cases micro-organisms were present; in one case the bacillus coli was obtained in pure culture; in another case the bacillus coli and the staphylococcus albus; and in a third case the bacillus coli and a Gram-positive staphylococcus. A bacteriological examination was made from the surface of the intestine in 45 cases and this was found to be sterile in 29. On ten occasions a pure culture of the staphylococcus albus was obtained; in one case the staphylococcus cereus albus; in three the bacillus coli; in one the bacillus coli and the staphylococcus albus; and lastly, in one case the bacillus coli and a Gram-positive staphylococcus. Anaerobic cultures were taken on eight occasions and were found to be sterile after several days' incubation at 37° C. in seven, while in the eighth case a pure culture of the staphylococcus albus was obtained.

It will be obvious that the most important point is the frequency with which the staphylococcus albus has been found on the surface of the intestine in comparison with its presence in the sac fluid. In no less than ten cases this coccus was isolated in pure culture from the surface of the intestine, whilst we failed without exception to find it in the sac fluid. A bacteriological examination of the fluid alone would have led us to the erroneous conclusion that out of a total of 47 cases of strangulated hernia of all classes no less than 42 were completely sterile. This alone shows how careful we should be before we make use of terms such as "chemical peritonitis" or "peritonitis serosa."

The detailed results of our observations having been given there remain several general considerations which may now be examined. Micro-organisms were present in 33 per cent., the staphylococcus albus was found in 23 per cent., and the colon bacillus in 10 per cent. It is well known that as a general rule the proportion of gangrenous cases bears no direct relation to the duration of strangulation of the hernia because the tightness of the constriction, the presence of a protective pad of omentum, and other circumstances exert a controlling influence. But when examined bacteriologically the time element does appear to be of some importance. In those cases where the strangulation was of under one day's duration 86·6 per cent. were completely sterile; between one and two days, 55·5 per cent.; between two and four days, 50 per cent.; and over four days, 46 per cent. These figures show a steady decline in the proportion of sterile cases with the increase in length of the strangulation. The presence of the colon bacillus, however, appears to be unaffected as it was present once in each of the periods named. We have also endeavoured to ascertain whether previous taxis had any influence on the bacteriology but although it undoubtedly influences the appearance of the gut, particularly with regard to hæmorrhage into its wall, yet it seems to bear no relation to the bacteriology of the sac contents.

If the class of hernia is considered the result as regards the bacteriology is somewhat striking, for from inguinal herniæ organisms were obtained in 22 per cent., from femoral hernia in 46 per cent., and from umbilical herniæ in 60 per cent. Of the seven fatal cases no less than four were sterile and died from causes other than peritonitis. One case in which the staphylococcus albus was the only organism present died from obstruction by adhesions at the site of anastomosis, and at the necropsy there was only a little peritonitis immediately around the anastomosis. The two instances in which the colon bacillus was present died almost immediately after the operation, and at the necropsy a condition of diffuse peritonitis was found.

Whenever the colon bacillus was found in a case of strangulated hernia it was isolated both from the sac fluid and from the surface of the intestine. The staphylococcus albus, on the other hand, was never present in the sac fluid when it was absent from the peritoneal surface.

The relation of the bacteriology of the sac contents to the healing of the wound is one of interest. Apart from the cases where the colon bacillus was present the staphylococcus albus was found in pure culture on ten occasions. Not one of these cases suppurated. The three which did suppurate were completely sterile as regards the contents of the sac at the time of operation, so that the suppuration must have been due to extraneous infection. If the colon bacillus is present, then the probable outcome of the case will be death from diffuse peritonitis, but occasionally, under certain conditions, the result of its presence may be only suppuration of the wound. If the colon bacillus, however, is not present, then whatever may be the appearance of the gut there is no reason, *per se*, why a case of strangulated hernia should suppurate. Whilst we are fully alive to the fallacy of drawing general conclusions from a small number of cases we consider it to be at least suggestive that not a single case in which the colon bacillus was not present at the time of operation was followed by gangrene, perforation, or obvious peritonitis. We use the term "obvious" because we believe that peritonitis which shows little or no signs, and which is unattended by serious results, is of far more common occurrence than is usually believed. In the prognosis, then, the presence or absence of the colon bacillus is the factor of vital importance and this observation is of great interest in tracing the rôle which this organism plays in the vast majority of cases of peritonitis arising in connexion with the intestinal tract.

In the 53 cases of intestinal obstruction other than strangulated hernia micro-organisms were present in 30 instances. If we divide the cases into two periods, taking those of under 50 hours' duration in the first and those of over 50 hours in the second, there is a striking difference in the proportion of sterile cases. Of the 19 in the first class only four were sterile, whilst of the 34 in the second class 19 were sterile. Expressed in percentages, these in the first class—that is to say, the most acute—were infected in 79 per cent., whilst those belonging to the less acute class were infected in only 44 per cent. If we consider the situation of the obstruction and divide the cases according to whether the obstruction involved the small or the large intestine we find that where the small intestine was implicated 63 per cent. were infected, whilst in obstruction of the large intestine only 44 per cent. were infected. We are of opinion that the more frequent sterility of strangulated herniæ is due to the relatively smaller area of intestine available for examination. Believing as we do that organisms make their way out, not only at the site of most severe damage but also from all parts of the bowel as it becomes distended, we see that with [illegible] general peritoneal cavity the [illegible] nisms in the general cavity than in the sac of a hernia. Of the bacteriology of the general peritoneal cavity in strangulated hernia we know nothing but we believe that organisms would be found to be present there just as in other cases of obstruction were we in a position to investigate the question.

The character of the exudate in intestinal obstruction, from whatever cause arising, [illegible] the amount varies considera[illegible] depend upon the acuteness of [illegible] quantity can be estimated at the time of operation. As a rule it appears to be most abundant in intussusceptions which are perhaps the most acute cases in our series. In no case was the turbid fluid observed, which will again be referred to in dealing with appendicitis. In the film preparations of the exudate polynuclear cells were rarely seen, whilst mononuclear and endothelial cells were often present. Micro-organisms were only twice seen in cases where the cultures proved sterile. In these two polynuclear cells were present and the organisms were intracellular. The 14 cases of intussusception form a group of particular interest and will be considered separately.

We now give in a tabulated form the results which have been obtained in 53 cases of the peritonitis which is associated with intestinal obstruction.

	Peritoneal exudate.				Intestinal surface.			
	All cases of intestinal obstruction.	Intussusception.	Obstruction apart from intussusception.	The *acute* cases of obstruction.	All cases of intestinal obstruction.	Intussusception.	Obstruction apart from intussusception.	The *acute* cases of obstruction.
Number of cultures examined...	49	13	36	5	50	14	36	6
Number sterile	39	9	30	3	22	3	18	0
Number of cases in which micro organisms were found ...	10	4	6	2	28	11	18	6
Number of cases in which the staphylococcus albus was isolated by itself ..	7	3	4	1	20	10	10	3
Number of cases in which the staphylo*coccus* albus was isolated with other organisms	1	1	0	0	2	1	1	0

Analysis of the fatal cases is as follows. Of the 53 cases of obstruction from causes other than strangulated hernia 22 died. Of these, ten were completely sterile at the time of operation. We may rule out of account those that died from causes other than peritonitis, which are seven in number. Three cases, sterile at the time of operation—one an intussusception, one a carcinoma of the cæcum, and one a gall-stone impaction—died from peritonitis. In the case of the intussusception the peritonitis was due to subsequent perforation. In both of the other examples the obstructed bowel had been opened during the operation and doubtless the peritoneum had received its fatal inoculation by that means. The explanation lies in the exalted virulence of the organisms present in obstructed bowel. Operations of resection or of short-circuiting performed during *the existence of* acute obstruction are attended by a higher death-rate than when done in a condition of intestinal repose. Corner has expressed the belief that the leakage of an anastomosis is not due to imperfect suturing so much as to infection along the stitches, and this view is upheld by the bacteriological facts. It is therefore on bacteriological grounds as well as on those of practical experience that one should as far as possible avoid opening the bowel during acute obstruction. If it becomes necessary to empty coils of intestine in order to be able to proceed with the operation grave additional risk is run. If resection or colotomy has to be performed they should be rendered *as far as possible* extra-abdominal manœuvres by appropriate suturing and packing.

In six of the 53 cases of obstruction the colon bacillus was present in the peritoneal cavity at the time of operation and of these not one recovered, death occurring in from a few hours up to the third day with one exception in which the fatal issue was delayed until the eighth day. This exception is of great interest. It was a case of carcinoma of the colon in a woman, aged 50 years, whose obstruction had been chronic for six weeks and acute for several days. The staphylococcus albus and the colon bacillus were isolated from the gut surface and the staphylococcus albus alone from the exudate at a distance. There was a minimal amount of clear fluid present, whilst the intestines were greatly distended and reddened. Colotomy was performed. Death took place on the eighth day and at the necropsy there was found a condition of universal peritonitis.

Prognosis.—We doubt whether a prognosis of much value would be derived from examining film preparations of the peritoneal exudate in cases of intestinal obstruction. All that we can say with any feeling of security is that positive evidence of the presence of the colon bacillus in the general peritoneal cavity affords sufficient ground for giving an extremely grave prognosis. Negative evidence, however, is of rather less value because it does sometimes, though rarely, happen that the colon bacillus makes its appearance after the obstruction has been relieved, as in one of our cases of intussusception. *If the intestine has been opened during* the operation then the bacteriological examination of the peritoneum is of no value whatever in indicating the probable termination of the case.

PERITONITIS DEPENDENT UPON APPENDICITIS.

Although the usual clinical distinctions are found by bacteriological examination to be only approximately accurate, we have found it convenient to follow that classification for the purpose of enumerating the 93 cases which we have examined. These are therefore considered under the headings of "diffuse peritonitis," "local abscess," "secondary complications," and "interval cases." The cases *of acute appendicitis, other than those of local abscess, we* have divided according to whether there was or was not a definite perforation present. In the one class are included some cases of gangrene and some of deep ulceration where the peritoneal tissue alone formed the wall; in the other are all degrees, from the minute perforation found only on close examination up to a complete diruption of the appendix. Our object has been to ascertain the bacteriological condition of the peritoneum as far away [illegible] as well as in its immediate [illegible] to inquire how far the resul[illegible] aspect of the cases.

Acute non-perforative appendicitis.—In three instances operation was undertaken before bacterial infection of the peritoneum had occurred. These were operated upon respectively 20, 27, and 48 hours after the onset of the illness and all of them presented very acute symptoms, the pulse-rate being increased out of proportion to the height of the temperature. In only one case was any exudate seen and this was a small quantity of almost clear fluid which microscopically contained enormous numbers of polynuclear cells. In each case the intestines in the lower part of the abdomen were reddened and distended. The appendices were remarkably unlike one another. One was a large, extremely thin sac containing pus, with a few flakes of lymph on its surface. Another was small, very œdematous, and of a bright red colour, with a small flake of lymph on its surface. The third was large, of uniform black colour, with a shiny peritoneal surface. There was no bleeding from the mesentery when cut across and the appendix was rigid, so that there was evidently thrombosis throughout the organ. On section the walls were found to hold myriads of micro-organisms.

Of these three cases one proved fatal from peritonitis, which was in all probability due to the fact that the distended small intestine was opened in order to empty it and to introduce magnesium sulphate into it. It may, of course, be said that the infection took place in removing the appendix, but we consider this not so probable, as the same method of removal—namely, by means of the clamp without opening the lumen—was in each instance employed and by the same operator. At the necropsy the stump was found secure. Moreover, evisceration and thorough irrigation were employed in the fatal case, whereas dry sponging was the method used in the other two. To this point attention will be directed later. In the other two cases no drainage was employed and the wounds healed by first intention.

In eight of the 11 non-perforative cases the peritoneum was found to be infected at the time of operation. In one instance the staphylococcus albus was the only organism present. The patient was a boy, 17 years of age, with a history of four days' illness. The pulse was 88 and the temperature was 102° F. The staphylococcus albus was isolated from the surface of the acutely inflamed appendix. The peritoneal exudate contained polynuclear and endothelial cells and the peritoneum at a distance was sterile. There were no adhesions. The appendix was large and swollen and in places exhibited necrotic patches. It was removed, the peritoneum in the neighbourhood was carefully sponged, and the abdomen was closed. Recovery was uneventful except that the wound suppurated.

In three instances the colon bacillus was the only organism found. One of these recovered but in this case, unfortunately, only the region of the appendix was examined bacteriologically, whilst the turbid, non-smelling fluid at a distance was not investigated. In this instance the illness had lasted only 24 hours. After removal of the appendix the peritoneum was treated by local dry sponging and drainage and the patient recovered. The second case was of three days' history in a boy, aged 13 years. Two types of exudate were present; in a remote region it was turbid and odourless, showed in film preparations large numbers of polynuclear cells but no organisms, and was sterile; in the immediate neighbourhood of the appendix, but not in a localised abscess cavity, there was thick offensive pus, which showed in films only Gram-negative bacilli and on cultivation grew only the colon bacillus. The appendix was removed and the peritoneal cavity was washed out and drained. Death took place on the tenth day and at the necropsy there was found a condition of universal purulent peritonitis. The third case was that of a child, three years of age, with a history of ten days' illness. The pulse was 150 and the temperature was 100°. At a distance from the appendix there was a quantity of turbid brownish fluid which in films showed polynuclear cells and Gram-negative bacilli but no other organisms. In cultures only the colon bacillus was grown. Immediately round the appendix, which was gangrenous but not perforated, there was thick foul pus, from which also the colon bacillus alone was obtained. The appendix was removed and the abdomen was washed out and drained but death occurred in a few hours.

In the remaining four cases of non-perforative appendicitis more than one organism was found: (1) bacillus pyocyaneus and staphylococcus albus both remotely and close to the appendix; (2) bacillus coli, staphylococcus albus, and staphylococcus aureus in both regions; (3) bacillus coli and a staphylococcus in both regions; and (4) staphylococcus albus alone at a distance and bacillus coli together with staphylococcus albus close to the appendix. The first three proved fatal but the fourth recovered after a severe struggle.

Perforative appendicitis with diffuse peritonitis.—We have examined 17 examples of this condition, the duration of the illness having varied from 36 hours to nine days. All were cases of what is usually called "general peritonitis" but the extent and degree of the peritoneal involvement varied considerably. In every case the changes were most intense in the right iliac fossa, and in those of longer history as a rule there had apparently been an abortive attempt at localisation, the thicker pus immediately round the appendix being feebly dammed back from the rest of the peritoneal cavity by agglutination of intestinal coils. In the worst cases of all there was no adhesion of any kind and the perforated appendix lay quite free in the peritoneal cavity. The exudate varied greatly in quantity and quality. In some there was no difference between that immediately round the appendix and that in the remote upper part of the abdomen; in others, again, there was a very distinct difference between the foul pus round the appendix and the turbid odourless fluid in the upper part. It is this turbid exudate to which we attach great importance from the point of view of prognosis; it is similar to that produced by experimental inoculation of the staphylococcus albus into the peritoneal cavity of guinea-pigs; it contains innumerable phagocytes.

In every case but one the colon bacillus was found free in the peritoneal cavity in the neighbourhood of the appendix, the one exception having the bacillus pyocyaneus and no colon bacillus. The peritoneum, at a distance, was investigated 15 times; on one occasion the odourless fluid around the spleen was sterile both in films and cultures, whilst the films showed many polynuclear cells. In one the staphylococcus cereus albus was alone present, in one the streptococcus pyogenes, and in one the staphylococcus albus and the colon bacillus. The colon bacillus was found alone on ten occasions. The relation of cover-slip examinations to culture methods, upon which so much stress is laid by those who regard the colon bacillus as of secondary importance, has been discussed elsewhere, but it is worth while in this place to draw attention to a striking point brought out by this series—namely, that on the one occasion in which streptococci were seen in the films they were also recovered culturally.

There does not appear to be any constant relation between the length of history of the illness and the bacteriological results. The colon bacillus may be found in a remote upper part of the peritoneum in less than 48 hours from the onset and, on the other hand, such a region may be sterile after five days' illness.

In discussing the result of treatment we consider together all the cases of diffuse peritonitis, both perforative and non-perforative, and these make up a total of 28. In 14 of these cases the colon bacillus was present in the exudate at a distance from the cæcal region; only three recovered. Two, in which the colon bacillus was found alone, were treated by appendicectomy, local dry sponging of the peritoneum, and drainage; the third had the staphylococcus albus present as well as the colon bacillus and was treated by removal of the appendix, general peritoneal lavage (but without evisceration), and drainage. Of the 11 fatal cases not one was treated by dry sponging but all by copious peritonea lavage, assisted, in the majority, by evisceration. These 14 cases, then, show a mortality of nearly 80 per cent. Now how do these results compare with the general run of cases of which we do not know the bacteriology? During the five years from 1899 to 1903 there were operated upon at St. Thomas's Hospital 119 cases of appendicitis with diffuse peritonitis. 100 were treated by washing the peritoneum with large quantities of sterile water or normal saline solution and of these 80 died. The remaining 19 were treated locally although the peritonitis was diffuse—that is to say, only the intestines in the neighbourhood of the cæcum were either sponged or washed over whilst the upper part of the peritoneal cavity was not interfered with, and of these ten died. The mortality, then, for general lavage is 80 and for local lavage or dry sponging only 47 per cent. It may be pointed out that perhaps only the less severe cases were treated by local cleansing but our reply is that we now know it to be impossible from examination at the operation to estimate the extent of the peritonitis, still less the nature and virulence of the infecting organism, so that selection of that kind is impracticable. On the contrary, the cases which our bacteriological examinations have taught us to be the less fatal are often the very ones which appear from the amount of the exudate to be the most severe and which would therefore probably receive the more energetic form of treatment.

The cases which have been operated upon by one of us, acting at various times for the surgeons at St. Thomas's Hospital, illustrate our point in a somewhat striking manner. Out of a total of 25 cases, 19 were treated by evisceration and thorough washing of the peritoneal cavity, the upper part being dealt with as thoroughly as the lower, and of these 18 died. The remaining six were treated locally, leaving the upper region of the peritoneal cavity undisturbed, and every one recovered. These cases were in no way selected, as, with one exception, they are the last cases in the series. One patient, in fact, was marked out for this line of treatment by the severity of his general condition, because he was much *too ill to stand extensive manipulation.* This was the case of a youth, aged 19 years, who had been ill for four days. The appendix was gangrenous and perforated, the intestines were everywhere inflamed and distended and bathed with turbid fluid which, odourless in the greater part, was of the usual smell in the region of the appendix, although not shut off by adhesions. The appendix was removed and the cæcal region was dry sponged and drained. The patient was extremely ill for two or three days but ultimately made a complete recovery.

An almost exactly similar case, treated differently, had a different result. A patient of the same age as the last had been ill for five days. The appendix was perforated and the intestines were everywhere red and distended. A large quantity of turbid odourless fluid was free in the peritoneal cavity even round the spleen. This exudate was thoroughly washed away with large quantities of saline solution, the appendix was removed, and the abdomen was closed. Death took place on the fourth day and at the necropsy a condition of universal peritonitis was found. Now the exudate was in this instance examined in two situations both by films and cultures. About the spleen it showed polynuclear and mononuclear cells but no organisms and remained sterile on cultivation. Close to the appendix the exudate showed polynuclear cells and Gram negative bacilli only and grew both aerobically and anaerobically the colon bacillus only. There can be little doubt that in this instance the interference with the sterile upper region of the abdomen not only spread the infection over a previously unaffected part but also washed away the phagocytic cells upon which the chief possibility of recovery depended.

Appendicitis with definitely localised abscess.—The bacteriology of the pus from a localised abscess is of little clinical interest, being practically the bacteriology of the intestinal contents. The very fact that it has become localised is evidence of a sufficient degree of power of resistance on the part of the patient. The peculiarly disgusting smell of the pus cannot be said to be characteristic of any particular organism. Veillon and Zuber consider it to be due to the various anaerobic organisms which they have isolated and Tavel and Lanz attribute it to what they term the pseudo tetanus bacillus. Four of our abscess cases, or 10 per cent., failed to show evidence of the colon bacillus, whilst the bacillus pyocyaneus was isolated from three of these four cases.

The condition of the peritoneum beyond the abscess, however, is of considerable interest. In most of our cases the abscess being adherent to the abdominal wall it was impossible to examine the peritoneum beyond, but in 16 instances the pus had to be reached through the general peritoneal cavity and these we examined bacteriologically. Nine proved sterile, whilst no less than seven grew a pure culture of the staphylococcus albus. In most cases there was an appreciable quantity of clear odourless fluid in the [illegible] ie intestines and omentum in [illegible] f the abscess were reddened [illegible] total number of 40 cases of local abscess only two died, neither from diffuse peritonitis. It appears that the opening of an abscess which is not adherent to the abdominal wall, provided that the peritoneal cavity is efficiently packed off with gauze, which is left *in situ* for two or three days after operation, is attended with little if any additional risk.

We were fortunate to observe two cases of appendix abscess which had to be reached through the peritoneal cavity, operated upon on the same day by the same surgeon and in precisely similar circumstances, a comparison of which offers significant support to our contention regarding the staphylococcus albus. One was that of a man, 34 years of age, who had had two previous attacks of appendicitis and had on this occasion been ill for 14 days. When admitted the temperature was 103° F. and the pulse was 100. The other was a boy, aged 13 years, in his first attack, who had been ill for five days. His temperature was 103° and his pulse was 112. In both cases the abscess was situated to the outer side of the cæcum. The general peritoneal cavity was first opened and in each instance contained a small quantity of clear odourless fluid, from which cultures were made. The peritoneal cavity was not packed off in either case but the abscess was opened and a drainage tube was inserted. From the foul pus the same organisms were obtained in both cases but the man's peritoneal exudate gave a pure culture of the staphylococcus albus, whilst the boy's was sterile. The subsequent progress was very different in the two cases. On the following morning the man was remarkably well, his temperature was 100.8°, his pulse was 88, the abdomen was soft and moving well, and there was no sickness or intestinal distension. Recovery was rapid and uninterrupted. The boy, on the other hand, presented a strikingly different picture. He looked seriously ill, with anxious facial expression, sunken eyes, and vomiting. The pulse was 142 and the temperature was 100.8°. The abdomen was rigid, moved badly, and was distended. Aperients and enemata were given with good result and on the morning of the third day the condition had begun to improve. The subsequent progress was good and recovery ensued.

There is a class of cases intermediate between the local abscesses on the one hand and the most acute perforative cases on the other calling for special attention because of the difficulty to which they give rise regarding the advisability of immediate operation. Opinion has gradually come round to the view that operation should be done upon nearly every case of appendicitis as soon as the diagnosis has been made, but the period about which alone any serious discussion still lingers is the period which lies between the second or third and fifth or sixth days. These are the cases in which nature is carrying on a hard fight against the invading organisms and the event hovers in the balance between the formation of a local abscess, when the natural protective forces may be said to have triumphed, and the rapid diffusion of the peritonitis which will if left alone lead inevitably to a fatal issue. The question whether at this stage nature can be assisted by surgery is one of the most difficult which the surgeon is called upon to answer. We therefore turn to bacteriology to see whether any light is shed by it upon the question.

There are six cases in our series which may fairly be said to come under this heading and may be set out thus:—

No.	Sex	Age (years)	Days of illness	Exudate at a distance	Exudate round appendix	Treatment	Result
1	F	21	Sixth	Sterile	Bacillus coli	General lavage	Died
2	M	18	Seventh	Staphylococcus cereus albus	"	"	"
3	M	19	Fourth	Bacillus coli	"	"	"
4	M	20			"		"
5	F	19	Third		"	Local dry sponging	Recovered
6	F	35	Fifth	Staphylococcus albus	Bacillus coli and staphylococcus albus	"	"

The conditions common to these six cases were that the colon bacillus was present immediately around the appendix in foul smelling pus which was feebly shut off from the inflamed peritoneum around by the agglutination of neighbouring coils of intestine or of omentum, and that clinically it was doubtful before and even at the time of, operation whether the condition was one of diffuse peritonitis or not. In three cases the colon bacillus was already present upon the peritoneum at a distance from the agglutinated area, one was sterile and the other two had staphylococci only.

What would have happened if operation had not been performed it is impossible to say, but it seems probable that the first three would have succumbed to the peritonitis which was already diffuse but not universal, whilst the other three might have formed a local abscess. The most important point, however, which is brought out in this table is that the four cases which proved fatal from universal peritonitis were all subjected to thorough washing out of the peritoneal cavity, whilst the two which recovered, although one contained the colon bacillus beyond the limits of the feebly shut off pus, were treated by local dry sponging and drainage. We conclude, therefore, that in these doubtful cases which present themselves for treatment after the second day of illness and before the formation of a definitely local abscess, whilst it is impossible to say what the outcome will be if left alone, yet operation may be performed without grave risk provided that every effort is made to limit the area of operation and to avoid the diffusion of septic material by too energetic treatment.

We now come to cases of infection at a distance from, but dependent upon, appendicitis, and we are able to compare the organisms found in these complications with those of the original disease. We have had the opportunity of examining two cases of subphrenic abscess, four other residual intraperitoneal abscesses, one case of empyema, one of abscess of the abdominal wall, one of acute pleuritis, and one of suppurative parotitis. These cases throw an important light upon the bacteriology of peritonitis originating in disease of the appendix and fall into harmony with our other observations, so that each deserves a brief notice.

Two cases of subphrenic abscess.—The first case was that of a female, 19 years of age, who had been operated upon three weeks previously for an imperfectly localised appendix abscess with diffuse peritonitis. A large quantity of turbid odourless fluid had been found in the peritoneal cavity and the intestines generally were red and distended. The patient was extremely ill at the time and nothing more than simple drainage was done. The turbid fluid proved to be sterile. The pus showed polynuclear cells and no micro-organisms in the films and gave on cultivation only the staphylococcus albus. The temperature kept high, the general condition was one of severe septic poisoning, and at the end of three weeks signs of pressure were noted at the base of the left lung. A large fœtid gas-containing abscess around the spleen was opened and drained. The patient recovered and ten months later the appendix was removed when practically no adhesions were encountered and the staphylococcus albus was isolated from the surface of the appendix. The pus from the subphrenic abscess showed polynuclear cells, groups of Gram-positive cocci, and Gram-negative bacilli. The cultures gave the colon bacillus and the staphylococcus cereus albus.

The second subphrenic abscess occurred on the right side. The patient was a boy, 15 years of age, who had had a localised, gas-containing abscess, from which a concretion escaped, opened 14 days previously. This had been shown to contain the colon bacillus and the staphylococcus albus. The temperature remained high and on the fifteenth day a small subphrenic abscess was opened. The pus contained the colon bacillus, the staphylococcus albus, and the bacillus proteus vulgaris. Two days later the patient died. At the necropsy similar purulent collections were found around the spleen and in the pelvis and the bases of the lungs were necrotic.

Other residual abscesses.—Of the other intraperitoneal residual abscesses two were close to the cæcum. The first occurred in a man, aged 22 years, who had had an abscess drained and the appendix removed two years previously and had been perfectly well in the interval. Films of the pus showed polynuclear cells, Gram-positive cocci, and Gram-negative bacilli. In both aerobic and anaerobic cultures the colon bacillus and the staphylococcus aureus were isolated. The patient recovered. The second was that of a boy, 12 years of age, who had had the appendix removed and the abdomen thoroughly washed out for diffuse peritonitis two years previously and who had been quite well in the interval. The pus from the residual abscess was thick and malodorous. Microscopically it showed Gram-positive cocci, Gram-negative bacilli, and polynuclear cells mostly degenerated. Both aerobic and anaerobic cultures remained sterile. The patient recovered.

Two other residual abscesses, one subhepatic and one on the left side of the abdomen, occurred respectively 17 and 30 days after the drainage of a local appendix abscess. Both contained thick odourless pus which showed polynuclear cells in the films. One, in which the pus was of a greenish colour, also showed a variety of bacilli and cocci, but on cultivation grew only the staphylococcus albus. The other showed exceedingly few bacilli, and these intracellular, and was sterile on cultivation. A case of perforative appendicitis in which the abdomen had been washed out and closed without drainage developed an abscess in the abdominal wall ten days after the operation. The pus contained the colon bacillus and a staphylococcus, both of which organisms had been isolated from the peritoneum. A right-sided empyema which proved fatal in a short time occurred in a man, aged 70 years. The pus showed Gram-positive cocci as well as Gram-negative bacilli but on cultivation grew only the colon bacillus. *Post mortem* the appendix was gangrenous and there was a large subphrenic abscess but no visible aperture in the diaphragm. A patient who had had an appendix abscess opened three weeks previously showed signs of pressure on the base of the right lung. Exploration for suspected subphrenic abscess was undertaken but no pus was found. Cultures from both pleura and peritoneum gave a pure growth of the staphylococcus albus. A case of left-sided parotitis occurred in a boy, aged 14 years, 24 hours after the opening of an appendix abscess of ten days' duration. The swelling gradually increased and softened and was incised on the fourth day. Soft necrotic tissue in very small amount was found deeply in the gland. Films and cultures were taken. The former showed only cocci arranged in groups and the latter gave a pure growth of the staphylococcus aureus. The right parotid gland was not affected. The patient recovered. Unfortunately we have no bacteriological examination of the pus in the abscess The patient's serum gave no agglutination reaction with the staphylococcus isolated.

Cases of appendicitis operated upon during a quiet period.—16 such cases have been examined: the peritoneum at a distance in 13, the surface of the appendix in 10, and the interior of the appendix in nine. The peritoneum at a distance was sterile in ten and showed the staphylococcus albus in three. The surface of the appendix was sterile twice and showed staphylococci eight times. The interior showed the colon bacillus alone seven times and staphylococci alone twice. The peritoneum at a distance was sterile in four out of six cases where the previous attack had been of the catarrhal variety; twice only was a staphylococcus found. The operations were performed from one to eight weeks after the attack had subsided. Of the cases where the previous attack had culminated in an abscess and where the patients had returned for appendicectomy with the wounds healed, a much larger proportion—namely, eight out of ten—grew staphylococci. The percentage of sterile cases after abscess formation is only 20, whereas after a catarrhal attack it is 66. The operations were undertaken from two to eight months after the abscess had been opened.

In the whole series of 16 cases suppuration of the abdominal wound occurred only four times and one of these was the case in which the staphylococcus aureus was present on the surface of the appendix. All the patients recovered. In one instance, after an interval of four months, a small collection of thick white odourless pus was found near the base of the appendix amongst some adhesions. From this a pure growth of the staphylococcus albus was obtained.

TREATMENT OF ACUTE PERITONITIS BASED UPON ITS BACTERIOLOGY.

It will be seen that the term "acute peritonitis" embraces a number of inflammatory diseases which differ widely in their symptoms, course, and prognosis. The main factors in these, as in inflammatory diseases of the cellular tissue, are the variety and virulence of the organism which has produced the disease and upon the power of resistance which the individual possesses against it. Unfortunately there is no opportunity of ascertaining what this organism is, in any given case, until after the operation, so that we can only act upon the knowledge of what are the organisms most frequently present in any given class of cases. In gastric and duodenal perforations, in intraperitoneal hæmorrhage, and in pelvic inflammations the organisms are, in the great majority of cases, of a mild type. In intestinal necrosis, on the other hand, it is the virulent colon bacillus which is by far the most common organism. The streptococcus pyogenes and the bacillus pyocyaneus are so uncommon and so uniformly fatal whatever the treatment adopted that it would be wise to treat all cases of peritonitis arising from intestinal necrosis as cases of colon bacillus peritonitis.

It is undoubtedly true that peritonitis of bacterial origin can subside without operative interference.

From what we have seen of the bacteriology of the peritoneum around an inflamed appendix it is impossible to believe that in all [illegible] appendicitis which subside without operation the [illegible] We also believe that in the cases [illegible] minate in abscess formation the peritonitis was at one time diffuse although no doubt of mild type and slight extent. But such terminations are not events to be reckoned upon, for at the beginning of an attack we can only conjecture what the bacterial infection may be and certainly none can foretell the result. The earlier operation is undertaken, therefore, the less likely is the peritoneal infection to reach a desperate stage. There are few at the present day who do not accept this view but there is still a wide difference of opinion regarding the extent of the operation which should be performed. Whilst there are those who advocate the most extreme measures of washing assisted by evisceration there are others, notably J. Murphy, who do not employ such drastic procedures. We are of opinion that the extent of the operation required depends upon the bacteriology of the case.

In streptococcic peritonitis, which is the most acute and fatal form that we know, it is doubtful whether any surgical procedure offers a prospect of success, but if there is any chance it must lie in the most thorough possible washing. At least this treatment can do but little harm, for the infective exudate is carried with such rapidity over the [illegible] washed away without robbing the patient of what in other forms of peritonitis usually constitute his chief line of defence. Peritonitis due to the bacillus pyocyaneus is of very little less virulence than streptococcic, but it is of rare occurrence and is impossible to detect at the time of operation. In this form, as in the other, the same line of treatment would offer the only possible chance of success, if indeed recovery from this infection is possible.

In the vast majority of cases, however, it is the colon bacillus which is the chief infective agent, and therefore most cases of peritonitis of intestinal origin must be treated as cases of colon bacillus infection. We believe that, from the observations which have already been set out, limited operations should be the rule, because of the mechanical impossibility of cleansing the peritoneum, the risk of washing away the phagocytes in the exudate beyond the area of most intense inflammation, and the danger of spreading infection over unaffected regions. In local treatment the question between local irrigation and dry sponging is of relatively small importance. We are inclined to believe, however, that dry sponging, so long as it is carried out with gentleness, is better than irrigation, because fluid poured into the abdomen is likely to carry infection beyond the area already involved. If those remote regions are already affected then no amount of washing is likely to be of much avail. In the case of mild infections, particularly those due to gastric perforations and intraperitoneal hæmorrhage, the washing should be thorough, with a view to remove the foreign material present, such as the contents of the stomach or blood clot.

The question of drainage is one upon which much has been written, but a great deal of the literature applies to the earlier days of abdominal surgery and concerns not only septic cases but all intraperitoneal operations. In mild diffuse infections, such as gastric perforations, intraperitoneal hæmorrhage, and the early stages of the peritonitis of obstruction, the organisms are comparatively harmless and can be safely dealt with by the peritoneum. It is the rule in such cases where the abdomen has been closed without drainage for the wound to heal by primary union. In severe diffuse infections, on the other hand, there [illegible] for drainage, although one [illegible] even suppuration of the [illegible] of local abscess the conditions are quite different. There is a definite cavity which for practical purposes is extraperitoneal and which can be drained. But where the peritonitis is diffuse the possibility of drainage depends upon the integrity of the peritoneum. In cases where fibrinous deposit is absent or insignificant, as in the gastric perforations, it is possible to drain, but where there is a sticky exudate present drainage becomes impossible because in a surprisingly short time the tube or other form of drain becomes surrounded by agglutinated intestine and omentum and its track becomes merely a sinus—a sinus, moreover, which is not without danger because extraneous organisms, particularly from the skin, have been found to extend with remarkable facility along such tracks. The objection of leaving a weak spot in the abdominal wall also is of some moment. We are therefore presented with the paradox that, apart from local abscesses, the cases which it is most desirable to drain are the very ones where drainage is impossible, whilst those where it is possible it is also unnecessary. In cases of gastric perforation where a tube has been left in the pelvis a large amount of fluid may be discharged during the first one or two days but in cases of appendicitis treated in the same manner it is remarkable how little fluid soils the dressings.

Next in importance to the operative technique in peritonitis comes the question of drug treatment. It is universally recognised that opiates should never be given before a diagnosis has been made on account of the concealment of important symptoms. But when once a diagnosis has been arrived at it is quite a common thing to see opiates given. If, rightly or wrongly, the decision has been arrived at not to operate, then the same objection still holds good, because when the patient is under the influence of opiates changes of vital importance which may at any moment occur are apt to escape notice. But there is an objection of little less importance than these which applies after as well as before operation. In obstructed or inflamed bowel the colon bacillus attains its maximum of virulence and in all probability under these conditions is able to make its way out at points other than the primary focus. It has yet to be proved that intestinal movements play any very important part in the spread of infection over the peritoneal surface. On the other hand, intestinal paralysis spells death, for it is of vital importance that the infective material shall be eliminated from the bowel at the earliest possible moment. A dose of morphine, superadded to the toxic paresis of the bowel, may just turn the balance against recovery. It is therefore obvious that the teachings of bacteriology harmonise with those of clinical experience in pointing to purgatives and not to opiates as the right drugs to be given in peritonitis.

Serum treatment.—The serum treatment of the septic diseases being in its infancy, and, so far, having shown only sporadic promise of the utility to which it may eventually attain, the little that we are able to say of its application to peritonitis can only take the form of speculation. We have endeavoured to show that in the large majority of cases of acute peritonitis it is the colon bacillus which kills the patient. At any rate it is possible to ascertain, in a given case, whether this is so very rapidly by means of cover-slip preparations and even of cultures taken at the operation. We believe that, did we possess a multivalent anti-bacillus coli serum the mortality of peritonitis would speedily diminish. At present we know of no such serum and we can only say here that experiments are in progress with a view to produce a multivalent serum against the various virulent strains of the colon bacillus which have been isolated from our cases of peritonitis. If films of the exudate were to show streptococci we might reasonably hope that one of the more recently produced multivalent antistreptococcic sera would prove of value. But the indiscriminate use of antitoxic sera in peritonitis, without regard to the bacteriology of the individual case, is to be deprecated as being as useless as it is unscientific. At least we have said enough to show that any hope based upon antitoxic sera must lie in the direction of a colon bacillus rather than upon a streptococcic antitoxin.

ABSTRACT OF

The Hunterian Lectures

ON

THE CHANGES PRODUCED BY INFLAMMATION IN THE CONJUNCTIVA.

Delivered before the Royal College of Surgeons of England on Feb. 27th and March 1st and 3rd, 1905,

BY M. STEPHEN MAYOU, F.R.C.S. ENG.,
CHIEF CLINICAL OPHTHALMIC ASSISTANT AT THE LONDON HOSPITAL AND AT THE ROYAL LONDON OPHTHALMIC HOSPITAL.

LECTURE II.[1]

Delivered on March 1st.

TRAUMATIC CONJUNCTIVITIS WITH SPECIAL REFERENCE TO THE CHANGES IN THE CELLULAR ELEMENTS AS THE RESULT OF WOUNDS.

Wounds of the conjunctiva.—Wounds of the conjunctiva occur as the result both of injury and of operation. Since the introduction of conjunctival flap operations for cataract and glaucoma a knowledge of the process of healing is of great importance, as after the flap is made the wound in the globe is shut off by it from direct communication with the conjunctival sac. Wounds in the conjunctiva are made also for the purpose of tenotomy, advancement, &c. Further, the conjunctiva of the bulb being largely free from cellular elements it offers one of the most favourable situations for the study of the early changes of traumatic inflammation, more especially as regards the formation, destination, &c., of the plasma cells, since these latter are of such frequent occurrence in all inflammatory conditions of the conjunctiva. In the course of some other work experimental wounds were made in the conjunctivæ of rabbits. At definite periods these wounds were carefully removed, fixed in alcohol, embedded in paraffin, cut transversely to the wound in serial section, and stained with logwood and dilute eosin and by Pappenheim's stain, the logwood and eosin showing the character of the cells with regard to their nuclei and the acid granules of their cytoplasm whilst the pyronine and methyl green of the Pappenheim stain showed the plasma cells and the various types of connective tissue cells, bacteria, &c. A preparation of rabbit's blood was made by fixing drops of blood in alcohol, embedding in paraffin, and staining by Pappenheim's method —adopting, in fact, the same process as that by which the sections of tissue were prepared.

---

[1] Lecture I. was published in THE LANCET of March 4th, 1905, p. 545.

[The experiments and the microscopic appearances of the *sections* were then described.]

CONCLUSIONS DERIVED FROM THE STUDY OF THE ABOVE SECTIONS.

A. Regeneration of the epithelium.—As the result of the contraction of the underlying elastic tissue the edges of the epithelium are turned downwards. As the result of the injury a few epithelial cells at the edges of the wound are killed, swell up, degenerate, and are probably either absorbed by the leucocytes or cast off in the discharge. The infiltration of the epithelium with leucocytes and plasma gives increased nutrition to the cells and therefore promotes their rapid division and spread and, further, by the phagocytic power of the leucocytes the destruction of organisms lying between the cells is carried on—a most important point, because although the conjunctiva always contains organisms it is very rarely that a wound of it becomes septic. Proliferation of the epithelium does not seem definitely to commence at the margin of the wound for at least 24 hours, nor could I find any evidence of it elsewhere beyond. The spreading margin is generally one cell deep, thickening taking place rapidly, as the growth of epithelium progresses across the wound. Should the growing epithelium meet obstacles, such as an exudation of lymph, in its endeavour thus to cover the surface, it becomes thickened, producing the peninsula-like processes which eventually dip down into the adjacent subconjunctival tissue and which are often only attached to the surface epithelium by a thin band. It is conceivable that if this band of epithelium subsequently atrophies from pressure of the contracting fibrous tissue it may leave a collection of epithelial cells in the deeper tissue which might become the seat of an implantation dermoid or even undergo malignant change. If the epithelium does not meet on the two sides the healing of the wound may be greatly delayed. The epithelium covers small incised wounds of the conjunctiva in 120 hours.

B. Changes in the subconjunctival tissue.—When the ocular conjunctiva is divided it retracts owing to the elastic tissue in its substance. The underlying episcleral connective tissue coming into the base of the wound the conjunctiva becomes firmly adherent to it in 48 hours, so that, arguing from analogy, it may be concluded that after a flap operation for cataract the wound is usually shut off from the conjunctival sac in that time. Generally some hæmorrhage occurs in which organisms seem to have the power to live, but any which gain entrance to the subepithelial tissue, except those in the blood clot, are taken up by the polynuclear leucocytes unless the wound becomes septic. A practical point, therefore, is to remove from wounds of the conjunctiva as much blood clot as possible. The leucocytes exuded during the first 24 hours are chiefly of the polynuclear type, and these cells possess a highly phagocytic power; indeed, unless sepsis occurs in a wound it is probable that these cells do not appear. After the first 24 hours, provided the wound be comparatively aseptic, the exudation consists practically of mononuclear cells only. Coinciding with this appearance of the lymphocytic exudation in the wound there is a large increase in the plasma cells. These latter cells and the lymphocytes appear around both the large and small vessels on *both* sides of the wound, which at this time have actively proliferating endothelium, and on the side away from the cornea are dilated to their fullest extent; they are also seen around the endothelium and perithelium of the gland tissue which has become incorporated in the base of the wound. The connective tissue cells at the deeper part of the margins of the wound show signs of proliferation. But although there is proliferation of these cells there are no plasma cells or mononuclear leucocytes in their neighbourhood. In the wound of 48 hours' duration the plasma cells have decreased in number and are mostly undergoing degenerative changes; whereas, on the other hand, the connective tissue cells are showing the greatest signs of proliferation, without forming true plasma cells such as are found in the exudation of lymphocytes, although a few scattered plasma cells can be found in the neighbourhood of the new vessels. In the wound of 120 hours' duration there are practically no well-formed plasma cells except in situations where there is still an exudation of lymphocytes.

From all these observations, therefore, it appears to me that the origin of the true plasma cell is probably not the connective tissue cell but that it is derived, with the lymphocyte, directly or indirectly, from endothelium or perithelium.

To recapitulate: 1. *The plasma cells make their appearance* at the time when lymphocytes appear in the wound, and it is then that they are found in the greatest numbers; the connective tissue cells in the deeper parts of the wound, although commencing to show changes, have practically no plasma cells around them, which seems to me strongly against their origin from the fixed connective tissue cells, but where the perithelium covering the gland tissues comes into the base of the wound it is packed around with plasma cells and mononuclear leucocytes. 2. They are arranged principally around the blood-vessels on both sides of the wound, being found equally near those containing blood and those containing practically no blood, and they are also found within them. Many of the vessels around which the plasma cells and mononuclear leucocytes are found have such thick walls that it is impossible to suppose that they have come through their walls. 3. They begin to disappear in 48 hours, when the lymphocytes decrease, and persist in any number only at the actual site of exudation of lymphocytes. 4. When the connective tissue cells show the greatest activity the plasma cells have to a large extent disappeared and the majority of those which remain show signs of degeneration.

These facts being taken in conjunction with the fact that plasma cells in all stages are to be observed developing from the endothelium, and, as will be shown, that in the lymphatic glands, in which the mononuclear cells are produced, there are found plasma cells, I think the evidence is strongly in favour of the origin of the plasma cell being with the mononuclear leucocyte from a common source, most probably the endothelium or perithelium.

Against the view of the origin of the plasma cell being endothelium, I have examined preparations from the pleura of a rabbit injected 48 hours previously with paraffin. The section showed much proliferation of the endothelial cells on the surface but there were no definite plasma cells lying between them. Directly beneath there were considerable numbers of plasma cells. J. Briscoe,[2] in examining the fluid from the peritoneal cavity of rabbits at various periods after the injection of normal saline solution, had been unable to find any plasma cells. Further, in examining some 15 cases of eyes enucleated for various acute inflammatory troubles I have never been able to find any plasma cells free in the anterior chamber, but in one case of chronic iridocyclitis there were numerous plasma cells present in the deposit on Bowman's membrane. This seems to point to the fact that it requires a special type of inflammation, usually of the very chronic variety, for the production of plasma cells in serous cavities.

Chorioplaques.—This form of giant cell appears in the peripheral parts of the wound in about 120 hours. It is rounded in shape, no doubt owing to the laxity of the connective tissue, and is derived from the plasma cells, its staining reaction and nuclei being similar. It appears as the plasma cells begin to disappear from the wound.

Giant cells proper, which have nuclei similar to the endothelial cells, are also seen in the wound of 170 hours' duration. They are evidently derived from the proliferating endothelium by the division of their nuclei without division of their cytoplasm. Thus in these two cells we have further evidence of the possible relation of the plasma cell to the endothelial cell

---

[2] J. Orth's Festschrift, 1903.

The blood vessels —The blood vessels show signs of commencing dilatation in six hours and at the end of 24 hours they seem to reach their maximum The leucocytes are found principally around their walls—that is to say, in the periphery of the blood stream—and the mononuclear varieties are more numerous within the vessels on the corneal side of the wound than in those on the other, cells identical in structure with lymphocytes and plasma cells can now be *seen budding off from their walls, at the same time the* endothelium shows signs of proliferation and at the end of 12 hours and at the end of 48 hours a quantity of newly formed vessels appear in the base of the wound

Lymphoid Tissue of the Conjunctiva

At birth, as has been seen, there is no lymphoid tissue in the conjunctiva—that is to say, the cellular elements are absent, although the connective tissue in the fornices is very loose in structure I have examined a number of conjunctivæ removed after death from children of various ages, from birth up to the fourth week, in which, so far as could be ascertained, there had been no previous inflammation or any silver nitrate or other irritant applied at the time of birth At birth the tissue is entirely free from lymphocytes and plasma cells There is no evidence of the so called germ areas of Ribbert and hence I think it is possible to exclude this theory in dealing with the conjunctiva After the first few days these cells begin to appear, chiefly around the vessels of the superficial layer in the superior fornix but also, to a less extent, around the deeper vessels; these cells gradually increase up to the fourth week when the lymphoid layer seems to be fully developed The fact that these cells appear first in the fornix is probably *due to the* extreme richness of its tissue in endothelium and perithelium as compared with the palpebral and bulbar conjunctivæ, the rapidity with which they form depends on the amount of irritation the conjunctiva receives, for if silver nitrate is applied at birth the lymphoid cells appear in 48 hours and all the endothelium of the vessels is found proliferating If we look at lymphoid tissue elsewhere at birth, such as in the tonsil or the lymphatic glands, we find it full of mononuclear leucocytes and plasma cells The cells are present for some weeks before birth and are evidently *produced* in these structures, probably from their endothelial lining

Going further afield we find that any connective tissue which is chronically inflamed becomes filled with these mononuclear cells It becomes a question, therefore, whether these cells are derived from the endothelium of the inflamed area, like those in the lymphatic gland, or whether they are brought to it by the blood stream Now in the case of the polynuclear leucocytes we are practically certain that they are brought by the blood stream, for it is found that they are increased in the blood and decreased in the organs in which they are produced during septic inflammation But in the case of the lymphocytes in chronic inflammatory processes there is no such increase of them in the blood, their number as compared with the polynuclear leucocytes being normally very small, so that they must either arise from a rapid division of the lymphocytes brought to the part by the blood stream or be a local production of the cells, probably from the endothelium at the site of inflammation This latter view is held by A Whitfield, with whom I strongly agree He looks on any endothelial or perithelial cell as capable of the production of mononuclear cells, in fact, he holds that any connective tissue can become lymphoid tissue This is only what is to be expected—viz, that a specialised cell, such as the endothelial cell, should revert to its simpler forms on rapid division

Further, it is a well known fact in surgery that after complete removal of glands new ones form and in cases of chronic inflammation new glands are found in unexpected places, such as in the muscles of the back, where we are taught by anatomists that there are no glands The conjunctiva seems to bear out this theory of origin of the lymphoid tissue from the endothelium most fully The subepithelial tissue of the fornix, being richest in endothelium, through irritation becomes filled with lymphocytes and plasma cells *varying* with the *amount* of irritation during the first few weeks of life, and if further irritated by atropine or any other form of chronic irritation it takes on the formation of typical lymphoid follicles, which are identical in structure and character with a minute form of lymphatic gland and behave both in health and in disease in a similar way to those structures, further, in Parinaud's disease we have the association of follicular formation with glandular enlargement Nothing to my mind can be stronger evidence than this of the local production of the lymphocytes and plasma cells

The importance of the early formation of the lymphoid tissue as a protection will be suggested in connexion with infection in ophthalmia neonatorum and the action of silver nitrate as a prophylactic in that disease The lymphoid *tissue appears first in the fornices and then spreads to the* palpebral conjunctiva It varies in extent with the amount of inflammation in the conjunctiva Unless inflamed the bulbar conjunctiva contains no lymphoid tissue and even then the mononuclear leucocytes disappear after the subsidence of the inflammation but even in this situation follicles occur in cases of very chronic inflammation, such as in trachoma of the limbus Plasma cells are always found in the lymphoid tissue, both in the conjunctiva and elsewhere unless the tissue be diseased, as is the case in follicles infected with trachoma and tubercle when the cells become rapidly broken up They are less numerous in rapidly formed follicles and in new lymphoid tissue than in the older parts They become increased in any tissue subjected to chronic irritation and a notable instance of this is the bulbar conjunctiva when irritated by the friction of the trachoma granules, but they disappear at the foci of a disease affecting the tissue as will be seen later We now pass on to the histology of the follicular formation

Follicular Formation

So called follicular conjunctivitis is characterised by the formation of follicles, which appear chiefly in the lower fornix Occasionally in severe cases they are found in the upper fornix and on the tarsal conjunctiva Their position in the lower fornix is a point of importance in distinguishing clinically this disease from trachoma, in which the follicles are principally situated in the upper fornix But the presence of follicles on the upper lid is not absolutely diagnostic of trachoma True follicular formations, such as are so commonly seen amongst children, give rise to no symptoms and produce no change in the conjunctiva, disappearing spontaneously without leaving any trace behind They can hardly, pathologically speaking, be called a disease since microscopically they are seen to be identical in structure with the follicles *found* in the ordinary lymphatic gland and show a marked difference in structure to that of a follicle infected with trachoma, except perhaps in

both microscopically and pathologically, follicular conjunctivitis) and enlarged tonsils are found and the lymphatic glands all over the body are apt to become enlarged on the slightest *provocation Apart from children, these follicles* also make their appearance in general diseases of lymphoid tissue, as is sometimes seen in Hodgkin's disease They also appear after the application of irritants to the conjunctiva, as in patients who suffer from atropine irritation. It is therefore, seen that the follicle (1) may arise as the result of irritation, and (2) may be associated with general lymphatic enlargements As a rule both factors probably play an important part in follicular conjunctivitis As we have already observed the lymphoid tissue of the conjunctiva is of new formation The follicles in an ordinary lymphatic gland in which mononuclear cells evidently originate in no way differ from those of follicular conjunctivitis and I think *therefore* that these latter follicles may be looked upon as an effort on the part of the tissue towards the increased local production of mononuclear cells, either as the result of irritation or of general increase of the lymphoid tissue Further, in Parinaud's disease we find follicular formation associated with glandular enlargement

The epithelium covering the follicles although thrown into folds, does not dip down into the tissue beneath, as in trachoma It is usually undergoing extensive mucoid change and especially is this evident over the tops of the follicles When this change is very excessive the epithelium is thinned and the follicles which lie directly beneath the epithelium no doubt occasionally rupture through it and subsequently become infected with pyogenic micro-organisms

---

[3] Coppez H Conjonctivite Folliculaire et Végétations Adénoïdes du Naso pharynx Archives d Ophtalmologie 1899 XIX 11

that give rise to the discharge which is sometimes associated with this disease and which, by producing further irritation, causes increased follicular formation.

The subepithelial tissue.—The follicles lie directly beneath the epithelium. They have sharply defined borders and there is a band of lymphoid tissue directly beneath the epithelium connecting one follicle with another. This lymphoid tissue in the neighbourhood of the follicles often contains a large number of plasma cells. The deeper layers of the conjunctiva are unaltered, there being comparatively no increase in the cellular elements or proliferation of the connective tissue cells, even in the cells in close proximity to the follicles. Occasionally, lymphatics and in some instances small veins are found packed with mononuclear leucocytes and plasma cells.

The follicles.—The follicles may be single or, as occurs when they are older and larger, they may contain masses of darkly staining cells which are due to the presence of another younger follicle within, thus resembling a lymphatic gland. They consist of a definite outer wall of endothelial cells which are often found proliferating. This outer wall is absent where the follicle is connected with the band of lymphoid tissue beneath the epithelium. Within the outer capsule of endothelium is a very delicate stroma, best seen in the older follicles. In this stroma are found occasional blood-vessels, also vessels which resemble lymphatics, since they are never found to contain blood.

The cells of the stroma consist of two types. The first form of cell making up the stroma is a typical endothelial cell. Some of these cells undergo a change, attention to which was first drawn by Leber. In connexion with trachoma he described these cells as containing "half-moon shape" and "coccoid-like" bodies, which he at first thought were parasites. Now if these cell inclusions be carefully examined the "half-moon shaped bodies" are seen to be not really half-moon shaped at all but round; that is to say, the chromatin, which is that which takes up the stain, is chiefly situated on one side of a round body, giving a half-moon shaped appearance. Numbers of the larger "coccoid-like bodies" show a pale centre with a darkly staining outer rim of protoplasm. Now these endothelial cells often also contain within them fully formed lymphocytes. The "coccoid and half-moon shaped bodies" are evidently produced by the digestion of the lymphocytes by the endothelial cells, all stages in the process being observable; they are not only found within the endothelial cells but also within the giant cells. As the cell inclusion is digested the protoplasm of the endothelial cell becomes vacuolated around it and when completely digested nothing but a vacuole is left. During the process of digestion the inclusion becomes more darkly staining, due no doubt to the shrinking and matting together of the reticulum of the cell. In a like manner whole plasma cells can be found within these endothelial phagocytes, the protoplasm of the endothelial cells around them becoming vacuolated until only the nucleus remains as a coccoid or half-moon shaped body. This endothelial phagocytosis takes place to an enormous extent in "resolving" follicles after the subsidence of inflammation and no doubt accounts very largely for the disappearance of the mononuclear infiltration after all inflammatory exudations. That this process of digestion of cells takes place in the endothelial cells elsewhere in the body (peritoneal cavity) has been shown to me by Briscoe,[4] some drawings from whose films I have made; they were taken from the peritoneal cavity of a guinea-pig two days after the injection of its own blood and show the inclusion of polynuclear leucocytes (pseudo-eosinophiles) by the endothelial cells and the process of their digestion. A similar change can also be seen in the endothelial cells on Descemet's membrane in cases of keratitis punctata.

The second form of cells making up the stroma are more typical connective tissue cells, with the ordinary pale blue nucleus and red nucleolus and badly staining protoplasm, when stained by Pappenheim's method. This cell is extremely rare in the follicles of follicular conjunctivitis.

The third form of cell, clasmatocytes or wandering endothelial cells, are large cells; their nucleus stains pale blue, with one or two red nucleoli, the cytoplasm staining red with Pappenheim's method. These cells are intermediate in structure between the endothelial cells and the plasma cells and cells are always found of which it is impossible to say whether they are clasmatocyte or plasma cells.

The cells of the follicles.—The character of the cells varies somewhat with the age of the follicle. In young follicles they consist very largely of mononuclear leucocytes (mainly lymphocytes) with a few scattered plasma cells. All the cells take the stain well, none of them show any signs of degeneration, and many can be found undergoing mitosis. In the larger and older follicles the cells, although consisting largely of lymphocytes, contain increased numbers of clasmatocytes and well-formed plasma cells. In some of the older follicles, as has already been mentioned, there are found collections of darkly staining cells with lighter centres, which are strongly suggestive of the commencing formation of new follicles inside the old (endofollicles). These groups are found in their early stages at the periphery of the follicle; some of the endothelial cells of the lining in their neighbourhood are proliferating, which probably furnishes their origin.

LYMPHOMA OF THE CONJUNCTIVA.

The most common situation for lymphoma is the inner end of the lower fornix. I have made sections from one such case in a female, aged 25 years, who some weeks previously had a mild attack of Koch-Weeks conjunctivitis.

The epithelium over the surface had undergone some mucoid changes.

The subepithelial tissue.—The lymphoma consists of a mass of encapsuled lymphoid tissue. Directly beneath the epithelium, and therefore in the neighbourhood of the small vessels, there is a layer of plasma cells. The lymphoid tissue is arranged in an exactly similar manner to the lymphoid tissue of a lymphatic gland. The stroma and the lining membrane of the lymphoma consist of endothelium and blood-vessels, numbers of the small veins of which are packed with mononuclear leucocytes and plasma cells. Within this stroma there are large numbers of typical follicles, consisting of mononuclear leucocytes and plasma cells. The follicles, at least in their early stage, are always found originating either from the endothelial lining of the lymphoma or from the blood-vessels within. The follicles contain, in addition to the lymphocytes and plasma cells, endothelial phagocytic cells and giant cells.

Conclusions.—In lymphoma, which is the outcome of previous inflammation, therefore we have the connecting link between the so-called follicle of follicular conjunctivitis and an ordinary lymphatic gland, the lymphoma being in size, structure, and probably in function identical with an ordinary small lymphatic gland.

[The description of cells found in the examination of the discharge in a large number of cases of both acute and chronic forms of conjunctivitis was then given and the following conclusions were drawn:—]

CONCLUSIONS AS TO THE CELLS OF THE DISCHARGE.

It may be said that in all the acute forms of conjunctivitis the discharge is principally made up of polymorphonuclear neutrophiles (94 per cent.) with an occasional polymorphonuclear eosinophile, but in some diseases, such as pemphigus and vernal catarrh, the numbers of the latter cell may be largely increased. The large mononuclears and lymphocytes each make up about 3 per cent. of the cells of the discharge. In the chronic forms of conjunctivitis, especially when the disease affects more the subepithelial tissue, as in trachoma, plasma cells are found in large numbers; they are also occasionally found in very small numbers in the discharge from acute conjunctivitis towards the end of the attack. Mast cells are found in the discharge principally in diseases of the subepithelial tissue, such as trachoma and phlyctenulæ but they are also occasionally found in the more acute forms of conjunctivitis when of long standing. The cells undergo degeneration by (1) vacuolisation, which seems generally to be due to the digestion of organisms, &c.; (2) hypochromatosis, gradual fading of the cell due to the absorption of fluid; and (3) pyknosis, shrinking of the protoplasm of the cell due to the loss of fluid, the latter two forms of degeneration depending on the osmotic properties of the cell wall.

CONTAGIOUS CONJUNCTIVITIS DUE TO MICRO-ORGANISMS.

Gonorrhœal conjunctivitis.—Clinically the disease is usually divided into two forms: (1) that found in newly born infants; and (2) that attacking adults. Newly born children are especially prone to infection of the conjunctival sac with micro-organisms, as has been previously shown, for the following reasons: first, the absence of lacrymal secretion; secondly, the epithelium is not so thick and there is no flattened layer as in the adult (numbers of the cells, especially in the fornix, have been lost owing to mucoid change which in places leaves the basement membrane bare), thirdly, there is an absence of leucocytes from the lymphoid tissue and fourthly, although the eyelids no doubt are closed as the child passes through the vagina they are in contact with the secretion for some hours before birth

THE CHANGES IN THE TISSUE AS THE RESULT OF OPHTHALMIA NEONATORUM

The following observations were made on three cases of ophthalmia neonatorum They were all extremely severe cases, one had ended in complete destruction of both eyes and the other two of one eye each

The epithelium on the surface is somewhat irregular in thickness and is desquamating some of the superficial cells containing the gonococcus The conjunctiva becomes papillated in consequence of the swelling beneath This is best seen in sections cut parallel to the surface when papillæ containing numerous blood vessels are seen completely surrounded by epithelium The epithelial cells are much separated from each other, chiefly no doubt by the passage through them of enormous numbers of polynuclear leucocytes *since the conjunctival sac will often become filled* with pus in less than five minutes after cleansing Many of the cells show evidence of mitosis Between the epithelial cells are found numbers of mononuclear and polynuclear leucocytes and although in the section the greater number seen are mononuclear cells the polynuclear cells are found in greater numbers in the discharge doubtless due to the greater power of amœboid movements on the part of the latter cells

The subepithelial tissue —There is an extensive exudation into the superficial layer of connective tissue the vessels in the deeper layer of connective tissue are dilated, and in and around the papillæ there are quantities of small vessels of new formation with proliferating endothelium These vessels contain large numbers of polynuclear leucocytes and show many beautiful examples of diapedesis The connective tissue cells of the superficial layer are proliferating but not to any marked extent The cells in the deeper layer of connective tissue show practically no changes

The cells of the exudation (polynuclear leucocytes)—Although these cells are found in large numbers in the subepithelial tissue they are not nearly so numerous as the mononuclear cells, their relative proportion becomes increased in the epithelium and in the discharge they make up about 94 per cent of the cells Hence it is seen that although they make up the greater proportion of the cells in the discharge they are not seen in such enormous numbers in the subepithelial tissue when compared to the mononuclear cells—a fact which can easily be accounted for by their more active amœboid movements Probably except in special circumstances these cells never re enter the circulation

Mononuclear cells —Mononuclear leucocytes both large and small are found in great numbers scattered throughout the exudation and are seen best in the papillæ which contain little else but these cells many of which are degenerating together with a few endothelial cells and new blood vessels

Plasma cells —Of great interest is the distribution of the plasma cell in this disease They are found in great numbers in the connective tissue beneath the papillæ but where they approach the epithelium they become rapidly broken up the cell staining more faintly and losing its protoplasm hence they are practically absent from the papillæ no doubt due to the presence of the toxin produced by the gonococcus growing in the epithelium The fact that the plasma cells become broken up is of great importance in showing the action of some powerful toxin on the cells and as will be seen in dealing with trachoma this fact is of great use in demonstrating the existence of a disease of which the cause has not been discovered I have been unable to obtain a specimen showing the early stages of this disease

KOCH WEEKS CONJUNCTIVITIS

Bacteriology —The bacillus of this disease is one of the most common causes of purulent ophthalmia being found all over the world The disease occurs frequently both in adults and in children in sporadic and epidemic forms often running through a whole school as it is extremely infectious Morax found 125 cases out of 1430 general ophthalmic out-patients Weeks Kartulis and Hoffmann have also pointed out that it occurs in epidemic form It almost invariably affects both eyes and is characterised clinically by intense injection of both palpebral and ocular conjunctivæ The injection in the ocular conjunctiva is very marked and there are numerous hæmorrhages all over the surface At the same time it is entirely free from chemosis I have examined 30 children with this typical clinical condition and have found the bacillus in 25 cases generally unassociated with any other bacteria In five out of the 25 cases above mentioned it was associated on the culture media with the staphylococcus albus pseudo diphtheric bacilli and diplobacilli From these observations together with the examination of a large number of cases by smear preparation I think it is possible to say almost with certainty *from the clinical condition* whether a case is due to this organism or not Towards the *end of the attack follicles form in the fornix which persist* for some time after the disease has subsided Hoffmann and Marl us have also pointed out the frequency of phlyctenulæ associated with this disease

Histology of Koch Weeks conjunctivitis —I have had the opportunity of examining the conjunctiva removed from the lower fornix at its junction with the ocular conjunctiva in two cases The first was from a severe case of the disease on the second day in a girl aged 20 years whilst the second was from a mild case on the eighth day of the disease in a man aged 30 years I have also examined a number of specimens from the lower fornix showing follicular formations, these follicles usually begin to appear about the sixth day of the disease forming rather earlier in children and persist for some time after the disease subsides

The epithelium —The epithelium shows extensive mucoid change which is not distributed evenly throughout but occurs in patches over the area of exudation into the subepithelial tissue and is more marked in the case of long standing than in the early case, the epithelium is occasionally found dipping down into the subepithelial tissue

The subepithelial tissue —The exudation unlike gonorrhœal conjunctivitis is unevenly distributed throughout the subepithelial tissue which contains between the patches of exudation very few more cellular elements than the normal number In the areas of exudation in the subepithelial tissue the vessels are dilated and the endothelium proliferating and there are quantities of newly formed vessels which are well marked in these areas in the sections from the case of two days duration there are also numerous small hæmorrhages into the subepithelial tissue The character of the cellular exudation varies in the two cases In the early case the exudation consists largely of polynuclear leucocytes but there are also numbers of mononuclear cells which are principally lymphocytes together with a few plasma cells these cells are found around the blood vessels of both the superficial and deeper layers the polynuclear leucocytes (spider cells) being more numerous around the small newly formed vessels whilst the mononuclear leucocytes are found around the larger vessels there are very few plasma cells present In the older case there are more newly formed blood vessels the mononuclear exudation is more marked and there are fewer polynuclear leucocytes than in the early case Plasma cells are present in large quantities where the mononuclear exudation is situated that is to say around the vessels, they are broken up wherever there are large numbers of poly [illegible] at the site of most active [illegible] ations do not differ in [illegible] follicular conjunctivitis In the early stages of their formation they do not contain many plasma cells These cells gradually increase in number as the attack subsides As the follicles begin to disappear the *endothelial phagocytic cells make their appearance* in enormous numbers and I have been able to count as many as 12 under a single field of the $\frac{1}{12}$th

From the above observations it is seen that in the early stages the plasma cell is not present to any extent but that as the disease subside and the tissues become locally immune it appears in increasing numbers Evidently the affection of the subepithelial tissue is much more localised than in gonorrhœal conjunctivitis as evidenced by the *unequal distribution of the exudation* but at the same time it is very acute as shown by the multiple hæmorrhages and polynuclear exudation This localised infection no doubt accounts for the frequency of phlyctenules and the localised hæmorrhages seen in the bulbar conjunctiva in this disease and also no doubt for the frequency of follicular formation after the acute stages have subsided

DIPLOBACILLARY CONJUNCTIVITIS.

W. Stock has examined a whole conjunctival sac from a patient who died while suffering from a chronic diplobacillary conjunctivitis. I have examined pieces of tissue removed from the lower conjunctival sac in three typical cases of two, three, and four weeks' duration. Although my observations are in the main similar to his he does not demonstrate the character of the cells by means of plasma stain.

The epithelium.—The greatest changes take place in the epithelium which undergoes very extensive desquamation and mucoid change. In the later stages of the disease it dips down into the subepithelial tissue and new glands are formed; these new glands are very liable to become occluded, with the result that retention cysts are produced.

The subepithelial tissue.—There is no increase in the polynuclear or mononuclear leucocytes in the subepithelial tissue, except in the regions where the epithelium dips down into it or where there are cystic formations. Elsewhere the change consists in a large increase in the number of plasma cells, of which the exudation consists almost entirely; directly beneath the epithelium the cells are somewhat broken up, no doubt due to the presence of the toxin. There is also a considerable increase in the mast cells of the underlying tissue. In one case which was of long standing there was a considerable amount of hyaline degeneration present. The diplobacillus is a non-pyogenic organism and causes a conjunctivitis which is extremely chronic if untreated but very amenable to treatment in the early stages. It produces the greatest changes in the epithelium in which it grows. The reaction caused by the toxin in the subepithelial tissue is not an exudation of polynuclear or mononuclear leucocytes, as is seen in the more acute forms, such as Koch-Weeks and gonorrhœal conjunctivitis, but is the production of plasma cells. These cells, as they come near the epithelium, are broken up through the presence of the bacilli and, therefore, owing probably to the low vitality of these cells, the disease is not eradicated spontaneously.

The Lettsomian Lectures

ON

TOXIC MENTAL DISORDERS.

Delivered before the Medical Society of London on Feb. 6th and 20th and March 6th, 1905,

By GEORGE H. SAVAGE, M.D. LOND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO, AND LECTURER ON MENTAL DISEASES AT GUY'S HOSPITAL.

LECTURE II.[1]

Delivered on Feb. 20th, 1905.

MR. PRESIDENT AND GENTLEMEN,—In the last lecture I commenced with a definition but it would be difficult to give any definition of toxic insanity and it is difficult concisely and with proper interest to place the subject fairly before you.

Mental and nervous disorders which depend chiefly upon toxic agents may depend directly upon them but also may not infrequently depend upon secondary toxins—that is to say, toxins which have been produced by the primary infections. A large number of nervous and mental disorders depend upon toxic agents and some of the toxic agents seem to have special or specific effects upon certain parts of the nervous system, leaving others comparatively untouched. In some instances the differences between one toxic cause and another is rather a question of degree than of the nature and though they may resemble one another in many aspects yet there is no doubt that some of these poisons are much more persistent or malignant, or both, than others. In comparing the effects produced by alcohol with those produced by lead we find that they are very similar in character, and in some cases hardly to be distinguished one from the other, but yet the effect of alcohol is as a rule transient, the effect of lead being more persistent and more serious. In the same way, if the effect of alcoholic poisoning be compared with that of syphilitic poisoning one has to recognise the great differences between the transient results of alcohol and the more invading and persistent infection of syphilis. The mental symptoms depending upon poisoning depend to a very great extent upon the quantity as well as upon the character of the toxic agent. There are certain poisons which if taken in large quantity will produce stupor, whereas if taken in only small quantities they have a stimulating effect. In the epidemics, such as scarlet fever, influenza, and the like, we constantly find at the early part of the epidemic a potent poison, whereas later it is less potent and has less serious effects upon the individual.

The frequency with which the poison is taken is of importance. A man who is having continuously repeated doses of poison suffers mentally and nervously much more seriously as a rule than the man who has one or more large doses of poison but not constantly repeated. There are specific peculiarities in poisons and there are specific differences in the persons poisoned. It seems probable that the neurotic individual is likely to suffer along the nervous side from infection much more than is the person who is not neurotic. It is believed by many that the infection of syphilis is much more serious when it attacks a person of neurotic but not insane inheritance—that the danger signal will be shown along the neurotic line whenever the affection occurs. There is a special idiosyncrasy as well; there are some people who are intolerant of the smallest amount of cocaine, and the smallest doses by instillation of atropine or of duboisin have produced most marked and serious mental disorders, temporary I admit but yet showing the extreme susceptibility of some people. Then, again, a person may become unstable and intolerant of any poison as a result of traumatism, such as sunstroke or any severe injury to the head or any strain.

First we will consider the toxic agents from without the body—that is to say those introduced into the body, such as alcohol, morphine, and the like. Then we will take toxic agents which form within the body as a result of some other infection, taking it for granted that it is not an influenzal infection or the syphilitic virus directly that produces the mental disorder, but that they set up a process which produces the toxin which gives rise to these troubles. Then we will consider the generation in the body of poisons the result of disordered metabolism; such conditions are to be met with in Bright's disease, in myxœdema, in diabetes, also probably in similar disorders depending upon a disturbance of healthy metabolism resulting from shock, fright, and alarm. Also acute delirious mania, the so-called acute delirium, or, according to some of the more recent continental writers, acute bacillary delirium. Then we have a very important class of cases of auto-intoxication from the gastro-intestinal tract. Then there is a fifth class which I am hardly prepared to accept as being different from the second, due to micro-organisms from without getting directly into the blood stream and thus producing acute infection. It is necessary to mention this in order to make the subject complete, but I shall not consider it. As to the general likeness which occurs under these conditions there is no question but that the following are the chief common characteristics. First of all the disorder is most commonly and in the earlier stages generalised and not localised. Next there comes a general confusion of function rather than anything else. Later we get sensory and motor troubles. Taking alcohol again we get staggering from the motor side and doubt and uncertainty and defective control on the mental. With the further development of the symptoms we get loss of higher control in the individual, loss of self-respect, he suffers in social relations after the attack, and he seems unable to fit in with his surroundings. Later come the craving and the desire for the cause and the falling before temptation. This does not exist in relationship to all the toxic agents and is much more marked with some than with others. Then another very important thing is to note the effect of most poisons sooner or later upon the storage mental capacity, so that defective memory is a marked and conspicuous sign. The end is generally dementia. In some cases there is comparatively small evidence that this result is impending. For instance, with certain poisons—belladonna, hashish, alcohol, and the rest—one gets an apparent brilliancy, which has been compared to cerebral usury leading to cerebral bankruptcy.

---

[1] Lecture I. was published in THE LANCET of Feb. 18th, 1905, p. 409.

The effects of the poisons may be either direct or indirect; they may at once seem to affect the nervous system, probably through the blood current, or they may seem to go directly through the circulatory and nutritional centres to the nerve centres. A certain number have not only direct but indirect effects; a poison which has affected the liver or one which has affected the kidneys chiefly reacts by producing further derangement or disorder of nutrition of the highest centres. It is important to remember that some poisons tend to produce moral defect, whereas others tend to sensory defect, others to muscular defect, and [illegible] There are, [illegible] or power of [illegible] and syphili[illegible] has to remember the persistency of certain poisons; it is a question whether a man who has once acquired syphilis is ever free from it. There is also the cumulative effect of such mineral drugs as arsenic [illegible] remembered. I would there-[illegible] toxic agents may depend [illegible] their persistency, or upon their cumulative power.

As to poisons from without, the first which I must refer to is alcohol. A large dose of alcohol may at once produce poisonous symptoms and stupor. Any agent which will produce any temporary nervous or mental disorder may produce a similar disorder in an aggravated form, so a very large dose of alcohol may render a man a fool, but it may render him permanently, or for days or weeks, a [illegible]

a time when the alienist is called in. It is difficult to know what to do with these cases. Probably they have been freely purged and all sorts of things have been tried to give them rest and sleep; they may have got into a condition in which they sleep fairly well and take food fairly well, and yet in their waking moments they are chronically mad. Some of these cases can only be treated by a hair of the dog that bit them. One hesitates to give alcoholics alcohol but sometimes it is necessary. Delirium following any form of mental disorder which can be produced temporarily can become permanent, a slight delirium may become a persistent delirium. Head injury, sunstroke, and the like [illegible] excessive consumption [illegible] some and dangerous sy[illegible] alcoholism are epileptic seizures. True epilepsy seems to be developed after middle age in some chronic alcoholics. Alcoholic insanity, so-called, which embraces alcoholic mania, alcoholic melancholia, and dementia, is characterised by delusions, hallucinations, and suspicions. The patients frequently become homicidal and not infrequently are in a maudlin, weak-minded state and become suicidal.

Perhaps I should say a few words about dipsomania. Is there such a disease as dipsomania pure and simple? Or is it simply a variant of recurrent mania in which there is a tendency to drink at the periods of depression? Nearly all the dipsomaniacs I have come across have belonged to neurotic families and have been liable to other attacks of nervous disorder. It seems to me interesting that dipsomaniacs do not tend to dementia so certainly or so rapidly as the ordinary drunkard. They seem to be able to recover completely from their disorders for a time. The most characteristic symptom of chronic alcoholic insanity is loss of memory for recent events, as in the mental disorders and the weak-mindedness which occur with senility, with decay, and, in fact, alcoholism may almost be called alcoholic senility. There is defect of memory for all recent events to a most extraordinary degree. And in passing I would say that one of the characteristics of this is that very frequently with the loss of memory there is loss of craving, loss of desire. Another almost characteristic defect of memory occurring with senility and also occurring in alcoholism is loss of the sense of time and place There is the individual who sits by his fireside and tells you that he has been to the office that morning, that he is sorry he has not changed his clothes but he was getting into his dressing gown, preparatory to dressing for dinner. As a matter of fact, he has not been out of the house for weeks. Or there is the individual who tells you that he is going home presently, he being in his own house where he has lived for years. This loss of appreciation of time and place relationship with the loss of recent memory is extremely interesting.

I will roughly sum up this part with these few remarks: that the nervous symptoms proceed apparently from the periphery to the centre; that sensation, motion, and intellect are in order affected. These lead to various mental disorders, to sensory disorders, giving rise to illusions or hallucinations such as of electricity, galvanism, or poisoning. Sensory defects, such as that of sight or hearing, lead to similar disorders of mind, confusion of ideas, with ideas of undue influence. Motor disorders probably play a part in the confusion as to time and place and also they cause ordinary giddiness. The chief marked intellectual defect is gradual and steady loss of mental power in all directions, loss of memory for recent events being the most characteristic. There is what I may call the sensory motor disorder seen in the epileptic; troubles so common in the advanced cases of this may be followed by a paresis resembling general paralysis or some form of local palsy. The progressive decay of the mind, due to alcohol, is marked by the progressive loss of moral sense, deadening of the feelings and of the higher civilisation, and later again in the onset of the affection a tendency to impulsive and dangerous acts. The form in which the alcohol is taken also has undoubtedly some effect. It used to be thought that there was little danger in beer, that there was some danger in wine, that there was still greater danger with spirit, and that liquors such as absinthe were specially pernicious—in fact, there was developed the term absinthism to indicate nervous disorders in which epileptiform seizures were particularly common.

Now to pass on to the next most important poison from without—namely, opium or morphine. The origin of the morphine habit (which occurs so commonly, unfortunately, in members of our profession and those connected with drugs) is often pain, more commonly sleeplessness, and extraordinarily commonly pure inquisitiveness. It is an interesting fact that I have rarely seen a serious acute attack of mental disorder follow the beginning of the taking of opium or morphine, even though a fairly large dose has been taken. I have seen a single large dose in habitual morphine-takers produce stupor, which has persisted, very similar to the stupor met with in alcoholics. As a rule, morphinomaniacs become such in a slow gradual way. There are slow progressive deterioration and loss of self-control, not so much loss of memory but an utter confusion of ideas, and there are disturbed ideas of time and place relationship. When mental trouble arises it not infrequently leads to profound melancholia, sometimes through the stage of acute mania when the morphine is withdrawn. Then the symptoms become acute and it is common for there to be at this time suicidal attempts. The moral decadence seems to be in relationship with the strength of the poison: a drunkard is a liar but a morphinomaniac is an accomplished liar. In some cases there is moral dementia out of all relationship to any intellectual defect. If with morphine there are ideas of poisoning and of persecution these are almost always associated with visual hallucinations, sometimes of the sensuous and sometimes of the sensual type. Not infrequently the individual who is poisoning himself accuses others of poisoning him.

Next to morphine I would refer to cocaine because it is not at all an uncommon thing to find that an individual who has been a morphine-taker, having made good resolutions and failed, determines to strengthen his good resolutions by taking cocaine. One advantage, from the medico-legal point of view of the cocaine-taker, is that he develops hallucinations of his senses which are readily detected and which call attention to his vice. The cocaine-taker hears voices much more commonly than the morphine-taker. The morphine-taker more frequently sees things, the cocaine-taker hears whispers and voices. Next to the auditory hallucinations are those of the skin. Persons who have been in the habit of taking cocaine will complain that there are worms under their skin, or will complain that by some means or other people are using the x rays or radium upon them. And such people, although there is n[illegible] will pinch it up and desire you [illegible] there. I have not come across [illegible] owed their origin directly to the use of cocaine. I have seen extraordinary susceptibility and in two cases I have seen temporary delirium and temporary stupor [illegible] the use of cocaine in the extraction [illegible] teeth.

seen the same thing follow on more than one occasion the instillation of atropine into the eye. Many years ago I heard somewhere that duboisin had been used as an exhilarant and I used it for dilatation of the pupils and one patient had, after the dilatation of the pupils, marked excitement, this patient having been melancholic before. I tried it in several other cases; in only one other did I meet with the excitement. Belladonna may produce delirium and there again, passing from the delirium, we may find delirious mania set up. In England we see nothing of hashish poisoning but it is only right to mention it in passing. When I was in Cairo some years ago I spent several days in the asylum there and saw a great many cases of delirious excitement depending upon hashish poisoning. The taking of paraldehyde even, loathsome as its taste is, may grow into a habit and may give rise to symptoms like those due to alcohol. I have seen one or two cases in which the taking of paraldehyde led to hallucinations of all the senses with ideas of persecution and poisoning.

Passing from the simpler poisons such as alcohol and vegetable poisons, I would refer briefly to mineral poisons such as lead. Almost any form of nerve disorder can result from lead poisoning. I have seen acute mania follow it. As a rule the symptoms are those affecting muscle rather than mind; they are cumulative in their effect. And what is most important is that lead alone or lead with alcohol will give rise to nearly all, if not all, the symptoms which are commonly met with in general paralysis of the insane. It seems pretty certain that lead will produce true general paralysis of the insane. I have seen cases of mental disorder following poisoning by coal gas. Following the use of any of the anæsthetics mental disorder may occur and I have met with several cases in which surgical dressings such as iodoform have produced temporary insanity.

Now comes, perhaps, the most important of all, next to alcohol, and that is the neurosis of influenza. Influenza, like other fevers, may set up any psychopathy, or any psychopathic changes may result from, or follow, influenza. Insanity may come on at various stages of the disease. One has seen influenza in an early febrile attack, with the temperature at 103° or 104° F., start acute delirious mania of a fatal type. One has seen the febrile stage of the disease give rise to maniacal disorders of various forms which may then start any form of insanity. The rôle of influenza varies in the production of the insanity. In some cases, undoubtedly, it is merely an exciting cause. People who have been subject to other attacks of insanity, sufferers from recurring mania or melancholia, get an attack of influenza and that again precipitates the attack. Therefore it may be the predisposing or the exciting cause of any form of mental disorder. But in nearly all cases where there is mental disorder following influenza it occurs in persons of neurotic inheritance or in those of a degenerate type. The alcoholic, for instance, may have been chronically alcoholic and not have suffered much from it perhaps, yet when he gets an attack of influenza he may become either a melancholiac or the victim of delusional insanity. The insanity follows, then, from an altered brain nutrition, possibly and most probably toxic, directly or indirectly. The onset of the insanity is often sudden and bears no relationship to the severity of the attack of influenza. Some of the most marked cases of insanity following influenza which I have come across have been those in which the influenza itself had been comparatively slight. The curability of the cases following influenza depends rather upon the form of the mental disorder than upon the severity of the influenza. Of course if the affection starts general paralysis of the insane or the evidences of general paralysis of the insane, it is no more curable because it was started by influenza than if it had been started by a blow or a shock. The insane are said to be less disposed to take influenza but I doubt it. It has occasionally had an interesting effect in curing psychoses. It is interesting also to remember that a person who is suffering from chronic insanity may, during an attack of influenza, have lucid intervals. There is no special indication so far as treatment is concerned.

The consideration of influenza leads to the consideration of neuroses following fever generally—that is to say, post-febrile disorders. One has seen disorder of mind following every one of the fevers. For instance, in typhoid fever there seems to be a post-febrile condition in which loss of memory is much more common than in any other disorder. In many of the others the mental disorder depends very greatly upon the fever and upon the delirious condition

It would be wrong for me to leave out gastro-intestinal auto-intoxications and I should like to speak of the acute delirious mania. Perhaps it is enough to say that one of the commonest symptoms which patients complain of when they come to me is constipation and indigestion—that is to say, various forms of gastro-intestinal trouble. Now and then the mental disorder has a direct relationship to the state of the stomach or of the bowels. And one has seen cases in which free purgation has brought about relief of the mental symptoms.

I have not time to speak of toxic conditions following upon surgical operations. I can only mention acute delirious mania or what has been called acute bacillary insanity. Under this head have been described cerebritis, acute meningitis, and by distinguished American physicians it has been termed delirium gravé. Acute delirious mania is a very good term unless bacillary infection can be proved. A shock of any kind will start a delirious condition, anything which alters rapidly and acutely the nutrition of the brain. I believe starting from the brain itself there may be auto-intoxication, a toxin which will produce delirium, and which develops into probably one of the most dangerous and fatal diseases which exist.

And now the time has arrived for me to sum up, and I feel that the whole subject must be left rather for your careful consideration; one has had to bring too many subjects under review. I do not wish to trace the origin of all mental disorders to micro-organisms, but I feel that we must accept the fact that associated with very many diseases there are bacillary growths, and yet that these micro-organisms are not the true causes. I would say that the part taken by such organisms varies greatly. I think the high tide of belief in bacillary causation has been reached and that we must next look for some cause of a physiological and chemical nature. But whatever we do we must be careful not to accept too readily the last idea, which is often very like the man seen against the sky who looks very big because of his position, and from that alone

---

ON THE DIAGNOSIS AND TREATMENT OF HYPERTROPHY OF THE PYLORUS IN INFANTS.[1]

BY GEORGE F. STILL, M.A., M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; ASSISTANT PHYSICIAN FOR DISEASES OF CHILDREN TO KING'S COLLEGE HOSPITAL.

THE importance of early diagnosis and of a clear understanding of the lines of treatment in the so-called "congenital hypertrophy" or "hypertrophic stenosis" of the pylorus in infants has become increasingly evident within the past few years, for it has been shown that what was formerly regarded as an incurable and inevitably fatal condition is, sometimes at least, amenable to treatment. Judging from my own experience I should say that many, perhaps even a majority, of these cases recover completely if only they are recognised sufficiently early and subjected to suitable treatment. I propose to deal chiefly with these two points, diagnosis and treatment, and my remarks will be based upon 20 cases which have been under my own personal observation either in hospital practice or in private consultation. Several other cases have been in the wards of this hospital and some of these also I have had the opportunity of watching, thanks to the kindness of my colleagues.

So much has been written recently about congenital hypertrophy of the pylorus that it is unnecessary to weary you with any detailed description of the disease; but let me remind you of its salient features. An infant under the age of four months has been vomiting his food. The vomiting began at the age of three or four weeks and for the first week or so was thought to be no more than a little indigestion might account for. But it persisted and soon began to attract notice, more by its persistency than by its frequency, for it occurred perhaps only two or three times in the 24 hours. Then the food was thought to be at fault and change after change was made in the feeding, each time, perhaps, with temporary diminution of the vomiting. But still the vomiting persisted and at times was noticed to be so sudden, copious, and forcible that the vomit was shot out a foot or more from the mouth and perhaps through the nostrils as well. Since the vomiting began the bowels have been costive, perhaps only opened with enemata. And now the infant is wasting to a marked degree and perhaps it is this wasting rather than any alarm at the vomiting which leads the parent to seek medical advice. Such is the history which leads one to examine specially for the two characteristic signs—visible and very marked peristalsis of the stomach and a palpable thickening of the pylorus—upon which the diagnosis rests.

---

[1] This paper is founded on a lecture delivered at the Hospital for Sick Children, Great Ormond-street, on Feb 9th, 1905.

DIAGNOSIS.

Having said thus much by way of general description I shall proceed to consider in detail the various points which bear upon diagnosis. But first let me emphasise the fact that no symptoms or combination of symptoms, however suggestive they may be, are sufficient for the diagnosis of congenital hypertrophy of the pylorus in the absence of the two characteristic signs which I have already mentioned. No doubt such a history as I have outlined would be strong ground for suspecting the existence of this disease and the suspicion might or might not prove correct, but where treatment, especially operative treatment, is so vitally serious a matter we have no right to be satisfied with anything short of certainty, and this depends upon the presence of well-marked visible peristalsis of the stomach, associated with palpable thickening of the pylorus.

Sex.—I would not have you imagine that any great stress is to be laid on sex in the diagnosis of this disease, but none the less I think that the predominance of males is noteworthy. Of my own 20 cases 17 were in males; only three were in females.

Age.—Far more important is the age incidence. On this point some misapprehension has arisen out of the nomenclature of the disease. More than once when I have seen these cases in consultation and have spoken of the condition as "congenital hypertrophy of the pylorus" I have been met with the objection, "But this is impossible, for the baby was perfectly well until it was four or five weeks old. How can the condition, therefore, be congenital?" Let me say at once that whatever may be the correct view as to the pathogeny of the disease, whether it be a congenital hyperplasia of the muscular tissue of the pylorus or a congenital lack of coördination with resulting spasm and thence hypertrophy, as Dr. John Thomson has suggested, or, whether the hypertrophy be entirely of post-natal development, the symptoms are very rarely congenital. Of my own 20 cases only one began as early as the third or fourth day and only three others within the first week. The term "congenital," therefore, is misleading and although I retain it as, perhaps, representing a correct theory there is no proof that all cases are congenital in origin. That the obstruction is primarily due to spasm of the pylorus I regard as certain and to me it seems most probable that the hypertrophy also is the result of spasm; how long this hypertrophy may take to develop we cannot tell; but so far as the spasm is concerned I see no reason why it may not, like the disturbance of coördination which is evident in the hiccough which babies so easily get, or in the stuttering which is almost physiological in the young child who is learning to talk, be due in some cases to irregularity of function beginning after birth; may not the nervous mechanism of the stomach be as easily disturbed as the nervous mechanism of speech, particularly in the early days before function has become stereotyped by usage? Perhaps, indeed, the analogy may be closer than this and the tonic spasms of the muscles of speech find a counterpart in a stuttering stomach. But however this may be, the point I would emphasise is this, that the symptoms very rarely date from birth; of my own cases, 12 certainly, and one other probably, dated symptoms (vomiting) from before the end of the fourth week; in the remaining cases vomiting began between the fourth and the end of the seventh week. It is not always possible to be certain of the date of onset, for slight regurgitation which the parents have regarded as normal and which may, of course, be so in early infancy, has sometimes been present before the definitely abnormal vomiting began. I have never seen a case in which vomiting began later than the seventh week, but onset at least as late as the ninth week has been recorded.

Obviously these facts have an important bearing on diagnosis. For example, in the case of an infant, aged nine months, who had been vomiting persistently for three weeks, a diagnosis of congenital hypertrophy of the pylorus was suggested but in such a case the age alone, apart from various other indications, was almost, if not quite, sufficient to exclude this condition. I am aware that the name "congenital hypertrophy of the pylorus" has been applied to a condition supposed by some to be identical herewith in the adult and if the disease is primarily spasmodic it is conceivable that it might begin at any period of life, but so far as children are concerned the onset of the disease is almost, if not quite, invariably before the age of three months and unless vigorous measures are adopted death usually results before the end of the fourth month.

Vomiting.—Let me insist first with regard to vomiting that, however persistent and chronic it may be, it is never *per se* proof that an infant has congenital hypertrophy of the pylorus. Cases have been recorded as instances of this disease with no other evidence than persistent vomiting; let me warn you against such an entirely unwarrantable assumption. No doubt it is the symptom which in most of the cases has first suggested the presence of this condition but it is only when it is associated with the characteristic signs, the visible peristalsis of the stomach and the palpable thickening of the pylorus, that it becomes diagnostic.

Apart from its persistency the vomiting of congenital hypertrophy of the pylorus has certain features which are suggestive of the disease. 1. Its forcible character. A mother informed me recently that her child with this condition "pumped up" his food suddenly with such force that it shot out more than two feet from the mouth. Her account may have been exaggerated but it may serve to illustrate my point. She also mentioned another frequent result of this forcible expulsion, that the vomit comes through the nostrils also. 2. Its occurrence in an infant who has been carefully fed, particularly when, as happened in 10 out of my 20 cases, the infant was being fed by the breast only. 3. Its persistence in spite of such alterations of feeding and such general treatment as will usually control the vomiting of dyspeptic conditions. 4. Its large amount showing that the vomit represents more than one feed, perhaps the accumulation of several feeds, in the dilated stomach. When vomiting in an infant under four months has these features there is very strong ground for suspecting the presence of congenital hypertrophy of the pylorus, but each of the four, including the forcing of vomit through the nose, has occurred within my own experience, also in cases in which there was no reason to suppose the presence of pyloric obstruction

I have referred incidentally to the fact that the vomiting is sometimes distinctly influenced by diet. In most cases the improvement is only short-lived, perhaps for a day or two, but I have known this to cause error in diagnosis; the temporary improvement with each change of diet was taken to indicate that the vomiting must be dependent simply on some fault in the feeding. The observation was correct, the inference was wrong.

Naturally much stress has been laid upon vomiting as a prominent symptom of the disease, but it must be remembered that the vomiting is not necessarily frequent; it may be only once or twice in the 24 hours. There may even be an interval of 24 hours in which there is no vomiting. No doubt this depends to some extent upon the degree of dilatation of the stomach which has occurred but I suspect that it means more and points to [illegible] tion, a variation which see[illegible] varying degrees of spasm o[illegible]

As the result, no doubt, [illegible] some cases this symptom has sometimes attracted much less attention than the wasting which accompanies it, and in two of my cases at least the vomiting was thought scarcely worth mentioning, the condition being regarded as simply obstinate infantile marasmus. In one of these both the medical attendant and the nurse stated that the vomiting was "nothing particular," but on cross-questioning one found that the vomiting, although it occurred sometimes only once in the day, was often more in amount than one or even two feeds and that it was shot out with unusual force through the mouth and nose.

Constipation.—The association of chronic constipation with this persistent vomiting is of some importance in diagnosis, for where chronic vomiting in an infant at this age is dependent upon faulty diet it much more often keeps company with loose, or at least unhealthy, slimy stools and frequent action of the bowels. But there are exceptions in both ways. I have seen congenital hypertrophy of the pylorus with loose and frequent stools and I have notes of chronic vomiting with constipation in infants who showed no evidence of congenital hypertrophy of the pylorus. Nevertheless, I think it is a useful rule to examine carefully for congenital hypertrophy of the pylorus in all cases where chronic constipation is associated with persistent vomiting in an infant under the age of four months.

Wasting.—This, as already mentioned, may be the symptom which has attracted most attention and I only mention it again to warn you of the possibility of mistaking the case for one of marasmus from faulty feeding. I suppose there can be no doubt that until recently these cases of pyloric obstruction have mostly passed for the common marasmus of infancy or have been attributed to unsuitable feeding, and the mistake is easy enough to make, for the history may differ but little, if at all, from that of many a commonplace case of infantile wasting.

The two characteristic signs.—My own experience leads me to think that the condition is overlooked largely because the method of examination for the two characteristic signs is not generally understood. In three or four of my cases the presence of this disease had been suspected, but as the characteristic signs were supposed to be absent no diagnosis had been made, whereas when the case was examined under the requisite conditions the signs were shown to be extremely marked. In the first place it must be recognised that these two signs are only present at intervals, so that cursory inspection and palpation of the abdomen may, and almost always do, result in overlooking the condition altogether. Patient examination, occupying perhaps ten or 15 minutes, may be necessary before the signs can be elicited and occasionally, though, I think, rarely if proper precautions are taken, examination on a second occasion may be required. The reason of this is simple: both signs depend upon active contraction of the muscular wall of the stomach, and just as happens with the uterus during labour, at one time it is easily stimulated to activity and at another it remains inactive in spite of all efforts to excite contraction. The second point to be considered is the time at which the examination is to be made. I have almost always found that the abdomen has been examined without any reference to the time at which the infant was last fed and the result has been failure to detect the characteristic signs. The abdomen should be examined immediately after the infant has been fed. It is at this time, and apparently in some cases hardly at all except at this time, that the abnormal peristalsis of the stomach is to be seen, and it is during peristalsis that the thickened pylorus is to be felt. I think it is well also to watch the abdomen during the taking of the feed; sometimes after part of the feed has been taken vigorous peristalsis of the stomach commences. I would add as a third counsel, and one particularly applicable to these cases, that warm hands are no unimportant factor in the palpation of an infant's abdomen.

Visible peristalsis of the stomach.—Sometimes spontaneously, sometimes only after repeated stroking or gentle kneading of the epigastrium, a rounded lump, varying in size from half a large walnut to half a Tangerine orange, rises at the left costal margin and passes very slowly across the epigastrium slightly downwards towards the right hypochondrium. Before this lump has yet reached the mid-line a second similar lump is already rising at the left costal margin and sometimes before these two have yet disappeared in the right hypochondrium a third is already appearing on the left side, so that at one time three bulging eminences are seen like a chain of hills extending across the epigastrium. They move so slowly that at times they may even be seen to pause altogether but each in turn fades away in the right hypochondrium and a succession of these bulgings may continue to appear for one or two minutes. This peristaltic wave is so gross that it could easily be seen at a distance of two or three yards and in two of my cases the mother or nurse specially noticed it. Upon this grossness I lay some stress, for it is of importance in the diagnosis.

Two questions obviously arise with regard to the diagnostic significance of the sign: 1. Can any other movement be mistaken for this peristalsis of the stomach? 2. Does visible peristalsis of the stomach occur in infants apart from this disease?

There are two movements which I have known to cause doubt in diagnosis. One is the voluntary irregular contraction of the muscles of the abdominal wall, which in an infant "squirming" about as an infant often will, especially when the abdomen is exposed for observation, may cause local bulgings in the hypochondrium or epigastrium, but these, although they may deceive the unwary, ought not to cause any real difficulty, for the bulging produced thus does not travel transversely across the epigastrium, nor does it appear and disappear with the slow, even regularity of the gastric peristalsis; moreover, it is definitely coincident with voluntary muscular effort. The other movement is much more difficult to distinguish; it is peristalsis of the transverse colon in certain cases where, owing to an unusual arrangement of parts, peristalsis is from left to right in a portion of the colon. In an infant who was taken to King's College Hospital with vomiting at the age of five weeks I found definite but very slight peristalsis passing from left to right in the epigastrium; the pylorus could not be felt and the peristalsis was so slight that I doubted its significance. The infant looked ill and was admitted and died with broncho-pneumonia and pleurisy. It was found that the transverse colon passed across from the hepatic flexure towards the left hypochondrium and then turned back upon itself into the right hypochondrium before passing finally across the epigastrium to the splenic flexure; it formed, therefore, an S-shaped loop in one part of which, of course, the peristalsis would *travel from left to right*. In this case the feeble character of the peristalsis had suggested during life that it was not due to hypertrophy of the pylorus. With regard to the second question I think it may be said that visible gastric peristalsis of such marked degree as that to which I have referred is during the first few months of life almost, perhaps quite, peculiar to hypertrophy of the pylorus. So far as my own experience goes I have never known it to occur apart from this condition.

But I have purposely emphasised the degree of peristalsis, for I have seen in infants with chronic vomiting and constipation, where there was no other evidence of pyloric hypertrophy and where simple treatment by careful feeding and aperients caused rapid cessation of the vomiting, a very feeble peristaltic wave passing over the stomach just after feeding. I suspect that this might be found more often if specially sought. The peristalsis in these cases was so slight that it could only just be detected by inspection of the abdomen obliquely in a good light; the pylorus could not be felt. Of course, it may be argued that such cases were very slight degrees of pyloric hypertrophy, and this I cannot disprove. The peristalsis to which I have referred as a characteristic sign of hypertrophy of the pylorus, and which was seen in all my cases except the first (which occurred some years ago before the methods of examination were known to me), is something altogether more striking than this and if it happens to occur whilst the abdomen is uncovered is as obvious to the layman as to the medical man.

Palpable thickening of the pylorus.—On deep palpation, usually just outside the right nipple line and about a third of the distance from the umbilical level to the costal margin, a hard lump, barrel-shaped, and seeming perhaps about three-quarters of an inch long by half an inch wide, is to be felt *at intervals*. This tumour, the hypertrophied pylorus, behaves exactly like an intussusception in its variations of palpability. We are all familiar with the intussusception tumour, which at one moment may not be felt at all and the next moment is so hard that it is obvious to anyone. So it is with the pyloric tumour; it is during peristalsis that it is to be felt; at other times the muscle is so soft that no amount of *tactus eruditus* will enable you to feel it. For this reason palpation should be made during the visible peristalsis of the stomach and at these times I suspect that with experience the pylorus could be felt in every case, although perhaps more than one examination may be necessary. Out of my 20 cases the pylorus was distinctly felt in 19. Occasionally, even when there is no visible peristalsis in progress at the time, the pylorus can be felt evidently undergoing contractions, being palpable and hard one moment and completely lost the next. Such contraction may be excited by gentle kneading with the tips of the fingers pressed deeply into the abdomen in the situation of the pylorus.

It may be doubted whether any assistance is to be gained from an anæsthetic in this examination; indeed, it seems probable that it might actually prevent detection of the pyloric thickening by hindering indirectly the occurrence of peristalsis; certainly any anæsthetic is quite unnecessary; tact, patience, and warm hands are much more likely to be successful. No doubt the diagnosis of pyloric hypertrophy can be made with all but certainty from the visible, well-marked peristalsis of the stomach alone but it is my opinion that in every case the evidence should be clinched by feeling the thickened pylorus.

TREATMENT.

I shall preface my remarks by some general considerations on the treatment of this disease. You are all aware that within the past few years successful results have been obtained by operative relief of the pyloric obstruction— [illegible] method of relief which seemed at first to promise but littl [illegible] hope at so frail an age. But now it would seem that ther [illegible] is a danger lest the very brilliance of this success shoul [illegible] lead us into adopting as routine a mode of treatment which, however greatly methods may improve, can never be otherwise than dangerous in an infant a few weeks old. If the disease were incurable by other and fa [illegible] we might well accept the chanc [illegible] as I shall show you it is now [illegible] cases in which no operation whatever is necessary, and there are other cases in which the child's chance of surviving operation may be greatly increased by the use of simpler measures for a time until the infant is older and stronger and therefore in a better position for operative treatment. If, as I hold, the hypertrophy be merely a secondary phenomenon, the result of spasm, then we have a rational basis for adopting such treatment as may tend to allay the spasm, and if this can be done one may suppose that just as the hypertrophied muscles of the athlete degenerate when he ceases his exercises so the hypertrophied pylorus loses its hypertrophy and partly from the diminution in the thickness of its wall, but much more from the cessation of spasm, the obstruction ceases to exist. This seems to me the most natural explanation of the complete recovery which occurs in some well-marked typical cases under such simple treatment as repeated stomach washing and sometimes even with simple care in feeding. How these measures allay the spasm I know not, but that they do is I think actually demonstrable in the gradual disappearance not only of the vomiting but also of the two characteristic signs which I have mentioned.

Passing now from theory to more practical considerations I would warn you that by whatever method this disease is treated, whether by medical or by operative measures, the medical man must be prepared to give much time and much care to the case, not for a few days but for many weeks, if the infant's life is to be saved. It might be imagined that operation, inasmuch as it relieves all symptoms of pyloric obstruction forthwith, would solve all difficulties at once and that after the few days immediately succeeding the operation but little care would be required. As a matter of fact it is often far otherwise and the infant's life hangs in the balance for several weeks after operation.

One factor in success I will mention here, for it is equally important whatever method of treatment is adopted—namely, [illegible] in weight, so [illegible] of the utmost [illegible] juisite changes in the feeding may be many and may be of vital necessity and often have to be determined by the loss or gain of an ounce or two.

Treatment by dieting only.—As already mentioned, many cases are improved temporarily by change of diet, but it is probably very rarely that a cure can be effected by such treatment alone. Dr. H. Willoughby Gardner of Shrewsbury has published the case of a male infant whose vomiting began at the age of eight and a half weeks and who showed a peristaltic wave "almost the size of a small Tangerine orange" and had also a palpable thickening of the pylorus. The infant was fed with whey only for a time, then malt was added, then barley water and maltine were given occasionally, and gradually raw meat juice and white of egg were given also. For a long time all residue-leaving food was avoided and the amounts at each feed were only slowly increased from a teaspoonful every 20 minutes to two, three, and four teaspoonfuls at longer intervals. The [illegible] all symptoms disappeared, and [illegible] and a half months weighed 20 [illegible] ise in which the effect of even simpler dietetic measures was equally striking. A female infant, aged six weeks, was brought for persistent vomiting which had begun at the age of three weeks; the vomit was said to be "shot right out," coming through the nostrils as well as the mouth. The infant had been carefully fed with milk and barley water. A well-marked wave of gastric peristalsis was seen but on the two occasions on which I saw the child at this stage I was unable to feel the pylorus. The food was changed to peptonised milk and some bismuth was given. Four days later gastric peristalsis was still very obvious and vomiting continued; gradually, however, the vomiting became less and after about four weeks it ceased. The gastric peristalsis also gradually disappeared and when I [illegible] -lf months she [illegible] In this case [illegible] pylorus may [illegible] in absolutely certain but it does not alter the importance of the clinical fact that an infant with chronic, very forcible vomiting and with well-marked visible peristalsis of the stomach recovered [illegible] ith simple alteration of food.

[illegible] *by nasal feeding.*—My colleague, Dr. F. E. [illegible] published a case which I also had the opportunity of watching, in which an infant, aged 11 weeks, with typical symptoms and with the two characteristic signs pronounced, recovered completely with nasal feeding. All feeds (consisting of two ounces of milk and one ounce of barley water) were given by the nasal tube for 27 days, except on one day when bottle-feeding was unsuccessfully tried. I have not usc [illegible] hat it is lia [illegible] which, apart from operation, promises, I think, to be of most value and it is my own opinion that when careful feeding with some thin fluid, such as whey and raw meat juice, fails after a trial of a few days to arrest the loss of weight, which is the chief indication of the gravity of the vomiting, stomach washing should be given a trial in every case, the duration of its trial to be determined by its effect upon the weight. It is certain that some cases which, so far as can be judged clinically, are in every way typical instances of pyloric hypertrophy and which show just as marked signs, a peristaltic wave travelling in bulging prominences across the epigastrium and a hard palpable pylorus, recover completely and so far as my present experience goes show no tendency to recurrence after no other treatment than stomach washing.

The stomach is washed out twice daily for several weeks just before a feed and then once daily for some weeks longer with a solution of sodium bicarbonate (two grains to one ounce) through a Jacques's soft rubber catheter, No. 12 or 14. The frequency of the washings and the duration of treatment depend upon the improvement in the vomiting and espe- [illegible] remained almost stationary, or even [illegible] ounces at one weighing and regained its former level at the next, for two or three weeks, in one case for five weeks, before continuous gain began. So long as the infant is not definitely losing ground there is no need to rush to operation. Of course, with wasted infants at this early age every ounce is of importance and the utmost care and judgment [illegible] or against the continuance [illegible] long as there is any gain [illegible] my opinion should, be deferred. The food during this treatment has generally consisted of whey with raw meat juice or a very weak peptonised milk mixture, perhaps with a very small quantity of cream. As to the actual results of the treatment in my own cases, two recovered completely [illegible] the patience and perseverance [illegible] one patient was under the c [illegible] Streatham Hill and the other was under the care of Mr. C. F. Wakefield of Horley. The former patient I saw first at the age of eight and a half weeks; he showed, in addition to chronic forcible vomiting, very marked visible peristalsis of the stomach and at times the pylorus could be felt. He had lost 2 pounds ¼ ounce in weight since birth. The stomach was washed out first twice and then once daily for 19 weeks. All vomiting gradually ceased, the weight after two and a half weeks began to rise steadily, the two characteristic signs disappeared, and when he was last weighed at 14 months old he had been quite well for more than six months and weighed 23½ pounds. The other patient I saw first at the age of eight weeks. He was wasting and had been vomiting forcibly since six and a half weeks old; he showed the two characteristic signs in a marked degree.

Mr. Wakefield washed out the stomach at first twice and then once daily, then from two to three times per week for 16 weeks. During this time all symptoms and signs had gradually disappeared and the patient is now, at the age of two years and seven months, a bonny, healthy child weighing 35 pounds.

At the present time I have under my care in King's College Hospital an infant who, at the age of three weeks, was brought with the usual history and the two characteristic signs. My house physician, Mr. G. P. Young, has washed the stomach out twice daily for ten weeks and although for the first five weeks the weight was almost stationary and some vomiting continued the weight then began to rise and the child, whose weight on admission was 5 pounds 14 ounces and who was so feeble and puny that laparotomy would have been a desperate measure, has gained 22 ounces in the last five weeks and now weighs 7 pounds 4 ounces and has altogether more strength and vitality.

In another case an emaciated infant, with the usual signs and symptoms of pyloric hypertrophy, aged seven weeks, and already "almost too feeble to cry," was treated by stomach washing for six weeks; at first she gained weight slowly if at all and after about a month was only half an ounce heavier than when washing began; then she began to gain weight steadily and in 13 days had gained 13½ ounces. The child being now stronger it was decided to operate. From the day of the operation, although the vomiting was stopped thereby, continuous marasmus occurred and the child died in convulsions 25 days after the operation. It is easy to be wise after the event but here the steady gain in weight which had commenced before the operation makes it probable, in the light of the two cases already mentioned, that had the stomach washing alone been continued the child would have recovered.

In one case after washing out the stomach for 14 weeks there had been a gain of 22 ounces but progress was so slow that operation was done and the child recovered. In two other cases where stomach washing was done for a few days only there had already been slight gain in weight but it was decided to operate.

Whether the weight rises at once or not there is usually a marked diminution of the vomiting after the stomach has been washed out for a few days; but this must not be taken as an indication for stopping the stomach washing until the infant has been making steady and considerable progress in weight for several weeks.

Having said thus much of the success of stomach washing in this condition it is only right to mention its failures and possible risks; in four cases where stomach washing was tried for a few days only there was no improvement; in one case death occurred with some pyrexia about 48 hours after stomach washing was begun, and although the necropsy showed no evidence of vomited material in the respiratory passages death may have been due to matter drawn into the lungs in vomiting during the stomach washing; if so it must be an exceedingly rare accident, for I have had infants' stomachs washed out many hundreds of times without such an occurrence. In another case a dry rotten tube was inadvertently used and the end broke off in the stomach, necessitating immediate resort to the operative treatment which we had intended to defer; the pylorus was stretched, but an accidental rupture of its wall was overlooked (the operation was done in great haste owing to extreme feebleness of the infant), and death occurred about 27 hours later. Such exceedingly rare accidents must, however, weigh but little, and I think it remains true that stomach washing is a procedure which should certainly be tried in the pyloric hypertrophy of infants before resorting to operation; in some cases it is sufficient alone to secure complete recovery, in others by increasing the nutrition and the strength of the infant and by enabling us to postpone operation till the infant is a few weeks older it increases the chances of success from operation; where, however, the weight is steadily diminishing for several days in spite of stomach washing the question of immediate operation must be considered.

Lastly, I would insist upon an important point—namely, that the degree of gastric peristalsis (I mean the size of the bulging wave which is seen) and the palpability of the hard pylorus are no criterion of the possibility or even probability of recovery or improvement by stomach washing or of the likelihood of necessity for operation; the most pronounced signs and symptoms may occur in cases which respond well to stomach washing alone.

Operative treatment.—The actual operation to be done, if any be necessary, is a question which falls outside my province; forcible dilatation of the pylorus, pyloroplasty, and gastro-enterostomy have each their advocates. Nine cases out of the 20 included in my series (one of which was only seen by me once in consultation and was subsequently operated upon successfully by Mr. H. J. Stiles of Edinburgh) were treated by forcible dilatation of the pylorus—all except one by my colleague, Mr. F. Burghard—and seven of these nine recovered. One of these died several months later from broncho-pneumonia. Operation has risks apart from those connected with shock and with the operation itself. There is a tendency to looseness of the bowels after it and also a difficulty of nutrition which in some of my cases seemed to make death from marasmus almost inevitable for some weeks after the operation, although they ultimately recovered; an important point this, which increases the need for careful consideration before embarking on operative measures, and which increases also the importance of previous stomach washing if thereby even a few ounces of weight can be gained.

As to the proportion of cases in which operation is necessary much more experience is required before a trustworthy estimate can be formed. It must be pointed out that three of the 20 cases in my series occurred several years ago before the modes of treatment were known and two are at present under treatment. In many cases, including several in my own series, stomach washing was not tried or was given up because it was assumed that the condition was incurable without operation. That in some of the cases operation is the only method of saving life is, I think, certain, but as I have already said there is no way of determining this until other measures have been thoroughly tried.

Harley-street, W.

ACUTE ASCENDING PARALYSIS IN CASES OF CHRONIC CYSTITIS.

BY T. J. WALKER, M.D. LOND.,

SENIOR SURGEON TO THE PETERBOROUGH INFIRMARY.

IN the comparatively limited field offered in my private practice, general and consulting, I have met with three cases of long-standing chronic cystitis which terminated fatally by acute ascending paralysis of a most malignant type. Although urinary paraplegia has been generally recognised by the profession for 70 years, since 1833 when Stanley directed attention to the malady in a communication to the Royal Medical and Chirurgical Society, I can find no allusion by authors dealing either with urinary diseases or with Landry's paralysis to the occasional association of the latter ailment with chronic cystitis. Stanley gives a short note of the case of a man admitted with gonorrhœa and phimosis into St. Bartholomew's Hospital, under the care of Dr. Erle, who died suddenly three weeks after admission and 12 hours after paraplegia had set in; but Stanley expressly mentions that the paralysis was not higher than the waist and as the man suddenly fell back in his bed and died the case was certainly not identical with those which occurred in my practice. Saundby gives the case of a man, aged 60 years, who was admitted into the General Hospital at Birmingham and who died four weeks after the onset of symptoms of a progressive paralysis. The disease here was possibly pathologically of the same nature although not showing the same terrible rapidity in its course as did the cases of which I will now detail the salient points.

CASE 1.—The patient was a man, aged 40 years. When 15 years old he fell astride a rail and injured his perineum. Ten years later he came under my care for retention of urine and stricture of the urethra and was treated in the Peterborough Infirmary. The retention had come on gradually, the patient having gone about habitually with a distended bladder. He never completely lost the chronic cystitis, which did not inconvenience him greatly and did not prevent his taking and working a baker's business. He seldom sought medical aid unless there was an acute exacerbation or some indication of the stricture requiring dilatation. In April, 1877, such an exacerbation occurred and the patient had been under treatment by my partner Dr G Kirkwood and myself for nearly a month when, on the morning of May 19th, I was sent for and found that in the course of the previous night he had felt numbness in the feet and some loss of power in the legs. When I saw him there was paresis of the limbs up to the thighs. By the evening the paralysis had extended upwards to the arms and the thorax and the breathing was already embarrassed The symptoms rapidly progressed and death took place 18 hours after their onset

No post-mortem examination was made but it seemed probable that some direct causal relation between the urinary disease and the rapidly fatal almost fulminating ascending paralysis must exist My notes of the case are very meagre but to the best of my recollection the patient did not require the use of the catheter or bougies during this last illness

CASE 2—The patient, a man, aged 62 years, was first seen by me about the year 1877, when, in consultation with Dr C N Elliott of Oundle, I operated upon him for a stricture of the meatus of the urethra for which he sought medical aid only when the symptoms of distended bladder and cystitis with painful micturition made his life intolerable A few years later, having come to live close to Peterborough, he came under my care and I learned that he had never lost his cystitis.

On Dec 31st, 1886, I was called to him on account of an acute exacerbation of his bladder trouble, accompanied with much malaise and some fever The symptoms were not urgent, there was no difficulty in micturition, and no catheter was passed I saw him again on Jan 2nd, 1887, when he was somewhat better He was not visited on the 3rd but on the early morning of the 4th he experienced uncomfortable sensations and some muscular feebleness in the lower limbs and at my visit about midday I found distinct indications of paraplegia The sudden onset of the paralytic symptoms, with the history of long standing cystitis, &c , and the feeble general condition reminded me at once of the case which I had seen ten years previously I gave a prognosis which led to the patient promptly settling his affairs By the 5th the symptoms had made considerable progress and early on the morning of the 6th, 48 hours after the first [illegible] patient succumbed. A necropsy [illegible]

CASE 3—This case was seen by me in consultation with the late Mr W J Pilcher of Boston, whose son, Mr C W Pilcher, has furnished me with notes of the case The patient, a man, aged 67 years, who resided at Boston, had for many years suffered from chronic cystitis and for the three months preceding his death had been under Mr Pilcher s care suffering from prostatic disease and cystitis requiring catheterisation He had been confined to his bed for some time On the morning of March 13th, 1894, when the patient got out of bed, he appeared feeble and unsteady on his feet He was catheterised as usual by Mr Pilcher and in the course of the day I was sent for I saw the patient at about 8 P M I noticed when I wished to feel his pulse that the movements of the hand and arm were impaired and on further examining into the history recognised that I had another case of the same character as Cases 1 and 2 Already, only 12 hours after the onset of the symptoms indicating implication of the nerve centres, the paralysis had progressed upwards until the upper extremities were involved With my experience of the former cases I gave *a prognosis of urgent* danger, demanding the immediate settlement of the patient's affairs This opinion was justified by his death 18 hours after the first onset of the paralytic symptoms No necropsy was made

Each of these three cases of progressive ascending paralysis is distinguished by the sudden invasion of the attack, by its terribly rapid progress, and by the fact that it occurred as the fatal termination of a chronic cystitis As to their pathology I am unfortunately able to give no certain information, they are recorded mainly for the benefit of those actively engaged in the prosecution of our art—those who, like myself, have little time or opportunity to advance our science

I can recall only two other cases of Landry s paralysis of this virulent type in which I have been consulted, so that my experience is that out of five cases of this malady three were associated with urinary disease, and yet by none of the authors whom I have been able to consult is this association referred to Farquhar Buzzard, in the important paper on the pathology and bacteriology of Landry's paralysis published in *Brain*,[1] speaking of the associated morbid conditions met with sufficiently often to justify their mention, names only two—enlargement of the spleen and evidence of extensive pleurisy in the form of old and recent adhesions. But in the light of my experience I cannot believe that the absence of recorded cases must be taken as a proof of the rarity of the association of Landry's paralysis with disease of the urinary organs , it is rather that this association never having been recognised as causal in its nature cases have not been published A very brief glance at the pathological history of the nervous affections known to be associated with disease of the bladder and at that of Landry's paralysis will, I think, help to show the probability of the occurrence of cases such as those which I am reporting in which, as I believe, the one disease gave rise to the other. Although rarely alluded to by writers on diseases of the urinary organs, "urinary paraplegia" has, as I have already said, been recognised since Stanley, in 1833, directed attention to the malady, accounting for it in accordance with the dominant pathological theory of that date as a form of reflex paralysis, and even 53 years before this Troja (as quoted by Leyden[2]) stated that violent inflammation of the kidney may produce an irritation of the nerves of that organ which may extend to the nerves of the spinal cord giving rise to paralysis and loss of sensation in the lower limbs

Gull, in a paper published in Guy's Hospital Reports for 1861, attacked the wavering faith in the nervous reflex view of the pathology of urinary paraplegia, contending that it was due to an inflammation of the cord which escaped detection in fatal cases owing to the imperfection of the examinations made at that time (1861) In this paper he enumerates the characteristics of urinary paraplegia under 15 heads, the second, third, and fourth of these being: (2) usually only lower limbs paralysed , (3) no gradual extension of the paralysis upwards , and (4) usually paralysis incomplete , from which it is clear that every character of "the symptom complex" (Farquhar Buzzard) which we call Landry s paralysis is wanting in "urinary paraplegia" as hitherto described

Leyden,[3] in a clinical lecture on the subject of reflex paralysis, goes fully into the history and pathology of urinary paraplegia and he concludes that in a considerable number of cases of paraplegia urinaria an anatomical affection of the cord has been proved in the form of a myelitis which begins in a circum*scribed lesion in the upper part of* the lumbar enlargement He assumes that the inflammation first passes to the nerves and induces in them a progressive neuritis which as has been proved by experiment may lead to myelitis He concludes that this may therefore be looked upon as the most natural *and frequent mode of occurrence* in paraplegia urinaria

Hurry Fenwick,[4] who gives a fuller consideration to the matter than any other of the writers on urinary diseases whom I have [illegible] he points out that it would be rash [illegible] possibility of reflex paralytic sym[illegible] urinary diseases, accepts the more recent view of the pathology of urinary paraplegia as expounded by Leyden and others

Beyond this stage the pathology of urinary paraplegia has not been advanced I can find no record of bacteriological investigation in this malady Affections of the bladder associated with but secondary to, disease of the nervous system have *not, I think*, any bearing on the question under consideration, therefore I now pass briefly to the history of Landry's paralysis, by which I mean acute ascending paralysis such as that which proved fatal to my patients, a mortal malady which until now, as Farquhar Buzzard points out, is to us only a " symptom complex," not a disease

Landry, in his original paper,[5] published ten cases of ascending paralysis showing a pernicious and malignant cha[illegible] of general progressive para[illegible] morbid conditions in the [illegible] these cases an absence of every appreciable nervous lesion This, which he regarded as the essential characteristic, can no longer be so regarded, as since 1859, when Landry s paper was published, the microscope, at first unaided by the various hardening and staining processes, and latterly with their most valuable help, has been brought into use for the examination of the nervous structures and the number of fatal cases of acute ascending paralysis in which no pathological change can be found has been proved to be very small. In the great majority there are microscopical changes in the cord and in the meninges such as could not be detected by the pathologists of 1859, and the opinion of the most recent investigators is that the symptoms are due to an acute intoxication of the nervous system caused by microbic toxins.

[3] Op cit

[4] Cardinal Symptoms of Urinary Diseases 1893

[5] Gazette Hebdomadaire de Medecine et de Chirurgie, vol vi , 1859.

Farquhar Buzzard, after a careful consideration of the results of the bacteriological and microscopical examinations of these cases, concludes that it has been shown by investigations on man and the lower animals that the clinical manifestations of Landry's paralysis are the result of a local infection, a general pyæmia, or, lastly and most frequently, of an acute intoxication. Beyond this stage he has himself advanced the pathology of the disease by his discovery of an organism which he regards as specific and as the cause of the disease, although he is careful to say that he does not as yet claim to have in any way proved that this is the only microbe that can produce the fatal toxins.

Assuming, then, that it has been proved by competent investigators that Landry's paralysis is an intoxication of the nervous centres due to infection by specific microbes and that urinary paraplegia is the result of the spreading from the urinary organs to the lumbar portion of the cord of a specific inflammation, I think we have grounds to justify a probable explanation of the pathology of the cases to which I am directing attention. In every infection three factors are necessary: (1) the presence of microbes having active infective powers; (2) a medium in which these microbes when conveyed to it can develop; and (3) the resistant power of the tissues must be weakened. I venture to suggest as a provisional view that in my cases these factors existed. First, the specific microbes were to be found in the urinary organs, probably in the bladder; secondly, at a certain stage of the disease they were conveyed along the same course, almost certainly the nerves, by which inflammation spreads from the urinary organs in paraplegia urinaria to the cord, in which medium they developed rapidly, producing a virulent intoxication; and thirdly, the tissues were weakened by the long-standing cystitis.

Whether this view be accepted or not, whether it be confirmed or disproved by future investigation, the clinical facts remain the same; and although in neither of my cases did my being able to come to a correct diagnosis and prognosis prolong or save the life of the patient, I look forward to the time when, the pathological association of this acute ascending paralysis and chronic urinary disease having been definitely established, remedial measures (probably organo-therapeutic) may be discovered which may stop the rapid course of the malady and avert its fatal termination. It is with this hope that I press these observations on the notice of my fellow practitioners and especially of those members of the profession who can devote themselves to pathological investigation.

Peterborough.

FURTHER NOTES ON THE AFTER-HISTORY OF CASES OF PYLOROPLASTY.

BY G. GREY TURNER, M.B. DURH., F.R.C.S. ENG.,
SURGICAL REGISTRAR TO THE ROYAL INFIRMARY,
NEWCASTLE-ON-TYNE.

IN THE LANCET of Feb. 11th, p. 351, there appeared a short paper on Pyloroplasty by Mr. Rutherford Morison. In that paper I am credited with having followed the after-history of his patients and in support of this some few brief particulars of the cases are given. As a matter of fact I prepared a table giving full details of each patient with a note of their progress up to the last time I heard of them in August, 1904. This table, very much to my regret, has been lost after leaving our hands. I wish to take this opportunity of amending the very brief particulars given in Mr. Morison's paper, so that those who are interested in this subject may be better able to judge why that surgeon still adheres to an operation which appears to have a rapidly waning popularity.

CASE 1.—The patient, a woman, aged 48 years, was operated on in October, 1894. The pylorus was thick and firm and would not allow a pair of closed Spencer Wells forceps to pass. She has remained well ever since the operation. She takes ordinary food and has very good health. In August last she weighed 10 stones 7 pounds, which is more than double her weight at the time of the operation and about three stones more than her previous normal weight.

CASE 2.—A woman, aged 37 years, was operated upon in October, 1895. The pylorus was bound down but was œdematous and reddened and on the upper margin there was a cicatrix; it only admitted the tip of the little finger. The patient has remained well ever since the operation. At present she has better health than she has enjoyed for years, can take any kind of food, and has no trouble whatever. In August, 1904, she weighed 9 stones—a gain of 1 stone 3 pounds since the operation.

CASE 3.—The patient, a man, aged 31 years, was operated upon in January, 1896. There was a hard nodular mass surrounding the pylorus which admitted the tip of the forefinger. The patient has been in very good health since the operation, has no stomach trouble, takes any kind of food, and in August last weighed 10 stones, a gain of 2 stones 7 pounds since the operation.

CASE 4.—A man, aged 32 years, was operated upon in August, 1896. The pylorus would only admit a pair of closed Spencer Wells artery forceps. The patient has remained well ever since; he went through the South African war without any stomach trouble and at present, in spite of drink and poor food, he has none of his old symptoms. When seen in August, 1904, he had just recovered from pneumonia and looked thin and ill but he was able to take as much of any sort of food as he was able to get. His general health is better than before and he weighs 9 stones, a gain of 1 stone 9 pounds.

CASE 5.—The patient was a man, aged 25 years, who was operated upon in October, 1896. The pylorus looked and felt normal from the outside but would only admit the tip of a Spencer Wells artery forceps. He has remained well since operation; his general health is better than before and he can take ordinary food. In August last he weighed 9 stones 7 pounds, a gain of 2 stones 7 pounds since operation.

CASE 6.—A man, aged 42 years, was operated upon in March, 1897. There was no organic change at the pylorus and it was then suggested that the symptoms might be due to spasm. The patient has remained fairly well since operation; he takes ordinary food in small quantities and has no vomiting but he complains that he does not gain strength. In August, 1904, he weighed 11 stones 10 pounds, a gain of 1 stone 5 pounds. He does his ordinary work.

CASE 7.—A man, aged 38 years, was operated upon in March, 1897. An ulcer was found on the posterior wall of the pylorus but there is no note as to stricture. This patient remained very well until the early part of 1901, when he had a "stomach attack," which lasted for two weeks; in spite of this in June, 1901, he weighed 10 stones—a gain of 1 stone 7 pounds. Since then he has had a recurrence of his trouble each spring; he had pain after food and vomiting, but between the attacks was fairly well. For about three months before his re-admission to the hospital in June, 1904, he was quite ill with pain and vomiting and had lost flesh. The stomach was very much dilated and the vomit contained sarcinæ. On exploration the stomach was found to be dilated and there was an œdematous mass at the pylorus but there was no certain evidence as to its nature. Posterior gastro-enterostomy was performed; he made a good recovery and there followed a very rapid gain in weight.

CASE 8.—A woman, aged 39 years, was operated upon in September, 1897. The pylorus would not admit the tip of the forefinger. The patient has remained very well since the operation, her health is better than before, and she takes ordinary food. Since she reported herself in June, 1902, she has vomited once or twice every three months but there are no other symptoms and her gain in weight is now greater than it was at that time. In August, 1904, she weighed 8 stones 3 pounds, a gain of 2 stones 1 pound since the operation.

CASE 9.—A man, aged 56 years, was operated upon in September, 1897. The omentum was adherent to the pylorus which was hard to the touch and only admitted the tip of a closed Spencer Wells forceps. The patient remained very well until two years ago when he began to suffer from indigestion with occasional vomiting; for two or three months he would remain free from symptoms but a year ago his attacks became more frequent. During the six months preceding the second operation he vomited every day and had to live entirely on liquids. At the second operation in May, 1904, the stomach was found to be dilated and there was a mass at the pylorus; there were no positive signs of malignancy. Posterior gastro-enterostomy was performed and up to the present he has done well.

CASE 10.—The patient, a woman, 46 years of age, was operated upon in November, 1897. The pylorus admitted the little finger. She remained very well until the autumn of 1903, when she had a transient return of her old symptoms. She can now take ordinary food and her general health is better than before and she has gained 2 stones 7 pounds, weighing in August last 7 stones 12 pounds.

CASE 11.—A man, aged 23 years, was operated upon in June, 1898. No ulcer or constriction was found and the symptoms were supposed to be neurotic. The patient has remained well without any of the old symptoms and he can take ordinary food. In August last he weighed 8 stones 6 pounds, a gain of 1 stone since the operation.

CASE 12.—A man, aged 41 years, was operated upon in [illegible]

[illegible] very well since the operation and has had no trouble beyond an occasional bilious attack. She takes ordinary food. In August last she weighed 8 stones 6 pounds, a gain of 2 stones 4 pounds since the operation.

CASE 14.—A woman, aged 39 years, was operated upon in November, 1898. The pylorus admitted the little finger. This patient was never robust, she has been better since operation and can take ordinary food with care, though she occasionally has pain and vomiting; before the operation the pain was continuous. In August last she weighed 6 stones 7 pounds, a gain of 7 pounds since the operation. In 1901 Dr. W. H. Mackinlay reported as follows: "Patient never was robust and is not now robust, but from leading a life of constant pain she now suffers an inconsiderable amount. She is profoundly grateful for benefit derived."

CASE 15.—The patient, a man, aged 46 years, was operated upon in November, 1898. The pylorus would only admit a closed Spencer Wells forceps and there was the scar of an old ulcer just on the stomach side of the pylorus. He has remained well ever since the operation. He has none of his old trouble, takes any kind of food, and in August, 1904, weighed 14 stones 5 pounds, a gain of 3 stones 5 pounds since the operation.

CASE 16.—The patient, a woman, aged 45 years, was operated upon in March, 1899. The finger could be passed through the pylorus but there was a scar on its posterior wall. For 12 months she was very well and could take any sort of food but at the end of that time she began to complain of her old symptoms, especially pain after food and vomiting. She continued to have "attacks" of stomach trouble and by June, 1903, she was in a miserable state, being afraid to eat on account of the pain which food produced; she had lost a great deal of weight. The abdomen was reopened; there were no great dilatation of the stomach and no mass at the pylorus, no ulcer was seen or felt in the interior of the stomach, and the new pylorus admitted three fingers with ease. Anterior gastro-enterostomy was performed and recovery was uneventful. For six months the patient remained well and was able to take any kind of food without trouble. She had gained 1 stone 4 pounds since the operation. Her symptoms now began to recur but she has not continually lost ground, for from time to time she has periods of good health without pain or vomiting.

CASE 17.—The patient, a woman, 36 years of age, was operated upon in May, 1899. There is no note of the condition of the pylorus but the stomach was very much dilated. She has remained well since the operation without ever having any trouble. In August last she weighed 8 stones 10 pounds—a gain of 2 stones 10 pounds.

It is scarcely necessary to add that in every instance the operation was performed for symptoms of stricture of the pylorus and that in every case physical examination disclosed a dilatation of the stomach.[1]

Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RUPTURE OF THE BLADDER IN A YOUNG CHILD.

By JOHN CROPPER, M.D. CANTAB.

ON Sept. 26th, 1904, a fellah boy, aged four years, fell from a flat roof 12 feet high on to his stomach, striking a coping of stone. He suffered great pain but when he was brought to me soon afterwards I could discover nothing beyond some bruising, especially on the left side of the abdomen. I was told later that he had voided urine the same evening. The next day the pain was worse with great distension of the abdomen and on my return in the evening I passed a No. 1 indiarubber catheter, drawing off less than half a pint of bloody urine at the patient's home, the catheter being left in position. The distension was considerably relieved and the bowels were opened. His pulse rate was 150 and his temperature was slightly raised.

I explained the condition of affairs to the parents, telling them that the bladder was certainly ruptured and that an operation was urgently required. On consultation with friends they refused either to have an operation performed or to allow the child to be taken into the hospital in Jerusalem. On the next day (Sept. 28th) he had slept and was much relieved; his bowels had been moved twice and he had passed urine twice; his temperature was 100° F. On the 29th the distension had increased and the motions were foul and light coloured. Five ounces of clear urine were passed but the child looked worse; his temperature was 99° and his pulse rate was 150. Seeing his condition and knowing that he had little chance of recovery the parents, convinced also by some very plain speaking on my part, consented to an operation which was accordingly performed under ether on the afternoon of the same day. Before the operation the patient had a very bad ashy-grey colour; his abdomen was tympanitic in the upper half, while the lower half was dull and firmly resistant, especially during the anæsthesia. An incision was made from below the umbilicus almost to the pubes. On reaching the peritoneum the bowel was found to be firmly adherent [illegible] to it, but on separating the [illegible] bloody urine at once welled [illegible] space bounded on either si[illegible] was very plainly felt. At [illegible] bladder could be felt. The rupture in it was of course intraperitoneal, was to the right of the apex, and admitted two fingers easily. Owing to the thickness of the abdominal wall (at least one inch of fat) and the length of time (three days) which had elapsed since the accident I considered that any attempt to close the bladder was out of the question. Certainly in the event of want of union the bladder sutures would have complicated matters and probably led to a fatal result. Accordingly I p[illegible] to the bladder and packed the [illegible] otherwise widely open. The [illegible] was 180. The patient slept well. Next day he was in very fair condition and enjoyed the ride of ten miles into Jerusalem to the Hospital of the London Jews Society, proper nursing being impossible in his own home. For the first few days there was a good deal of offensively smelling discharge with the urine which drained away freely. On using a considerably stronger lotion than had been used at first—namely, a [illegible] strength 1 in 2000 solution of [illegible] is twice daily—syringed thr[illegible] beyond a lit[illegible] the conditio[illegible] in an silver nitrat[illegible] painted on the wound there was nothing to note in the treatment. In spite of a smart attack of remittent fever with splenic enlargement the wound was firmly closed on Nov. 5th. The only trouble after this was incontinence of urine which persisted for some days. The patient was discharged from the hospital in very good condition four or five weeks later.

---

[1] See tables in The [illegible] of Feb. [illegible] l, and Med. Jour., Oct. [illegible]

In conclusion, it may be remarked that in native villages in this country almost the only accidents to children arise from falls from the flat roofs which are quite unprotected. In this case, as already stated, the child fell fully 12 feet.

Ramallah, Palestine.

NOTE ON A METHOD OF EXTENSION OF THE "GRIDIRON" OPERATION FOR APPENDICITIS WITHOUT DIVIDING MUSCLE FIBRES.

BY M. P. HOLT, M.R.C.S. ENG., L.S.A.,
MAJOR, R.A.M.C.

VERY occasionally the classical muscle-splitting operation unexpectedly fails to provide sufficient room. The following is a method which I have several times adopted of extending the area and which I have not seen described elsewhere. On such occasions the tendon of the external oblique is by a few touches of the knife separated from that of the internal oblique, where these begin to blend together for the formation of the sheath of the rectus, to well beyond the outer edge of the rectus and then retracted inwards; the line of splitting of the internal oblique and transversalis muscle is then carried on through their tendons well on to the rectus sheath for an inch or so; the remaining part of the anterior sheath of the rectus is then divided upwards, or downwards, whichever be desired, as far as is necessary; the rectus is then displaced inwards and the posterior sheath is similarly divided in a vertical direction, in a line a full inch nearer the middle line than the site of the outer border of the muscle. The triangular flap thus obtained is displaced outwards and downwards (or outwards and upwards, as the case may be). The incision in the peritoneum is easily extended to any desired point in the line of original incision and very free access is obtained. This method takes but a few minutes but its chief advantages are only obvious when the layers are severally united by sutures. When the posterior sheath of the rectus has been sutured, the rectus muscle secured by a few points in its original bed, and the anterior sheath similarly united, the internal oblique and the transversalis muscles will be found accurately lying together in the line in which they were split; the external oblique, of course, comes together without the least difficulty. In this way there has been no division of muscle fibres and the nerve- and blood-supplies to the rectus are practically untouched. The method provides precisely the same security against hernia as does the less extensive classical "gridiron" operation, a matter that cannot be overrated in young men. Drainage, if necessary, is made through a separate wound. I have used this method where a small localised abscess within omental adhesions due to a perforated appendix was found firmly glued to the posterior surface of the symphysis pubis and quite recently where an unusually long appendix was adherent by its tip behind the ascending colon close to the hepatic flexure, as well as in other less difficult cases. I quite recently saw in the dissecting room an appendix adherent throughout its whole length in front of the ascending colon, the tip lying actually on the hepatic flexure. Operating surgeons must necessarily have experienced many similar instances. I would emphasise that the method has only been used for those cases where the abdomen has already been opened by McBurney's incision and where investigation has shown that unexpectedly much more room is necessary and it is in no way recommended to take the place of a "right semilunar" incision. This method of extension of the "gridiron" operation can be demonstrated very easily on the *cadaver*.

I would add that Lennander's method of displacing the rectus *outwards* after a "right semilunar" incision is far preferable to that in which it is displaced *inwards*, as by the former absolutely no interference with either blood- or nerve-supply is risked.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

LEEDS GENERAL INFIRMARY.

TWO CASES OF DOUBLE MALIGNANT TUMOURS OF THE INTESTINES.

(Under the care of Mr. A. W. MAYO ROBSON, Dr. C. M. CHADWICK, and Mr. R. LAWFORD KNAGGS.)

CASE 1.—A man, aged 35 years, was admitted under the care of Mr. A. W. Mayo Robson to the Leeds General Infirmary on May 27th, 1902, with symptoms of chronic intestinal obstruction. These had commenced in December, 1901, and he had lost three stones in weight. No tumour could be felt in the abdomen and on examination the rectum was found to be healthy. At the operation on May 29th a stricture, causing almost complete obliteration of the lumen of the bowel, was found about the middle of the ileum. It was excised and end-to-end anastomosis was performed. No secondary deposits were seen. The growth (No. 2529 C in the Museum of the Royal College of Surgeons of England) is described as a portion of jejunum "which was excised for the close stricture shown, the constriction being due to the shrinkage accompanying the growth of a carcinoma which has invaded the muscular wall and advanced into the tissues beyond." It was obviously a carcinoma but no microscopical examination had been made as the interest of the specimen lay in the tightness of the stricture. The patient was readmitted on July 29th, 1904, under the care of Mr. R. Lawford Knaggs. He had had good health since the operation till about five weeks before, when he began to suffer pain in the sacral and left iliac regions and had experienced some difficulty with his bowels. In the scar of the old incision there were two hard masses. One at the upper end was as large as a walnut and involved the deeper structures of the abdominal wall. The other at the lower end was larger and felt as if it were not limited to the parietes but extended to parts beneath. Within the rectum, two inches from the anus, the finger impinged on a raised mass on the anterior wall which proved to be the indurated edge of an excavated ulcer large enough to lodge the terminal phalanx of the examining finger. The ulcer was about three-quarters of an inch deep. The mass was firmly fixed to the parts in front of the bowel. Several enlarged and hard glands could be felt between the sacrum and the posterior wall of the bowel and both glands and the posterior bowel wall felt tethered to the bone. Examination was not painful. A left lumbar colotomy was performed on August 2nd and the patient went home on the 17th.

CASE 2.—A man, aged 27 years, was admitted to the Leeds General Infirmary on Nov. 26th, 1903, under the care of Dr. C. M. Chadwick for an enlarged liver and a malignant growth in the rectum. He had suffered from typhoid fever when he was 21 years of age. In July, 1903, he began to have diarrhœa and to lose flesh. He had had "hæmorrhoids" for the last 12 months. He suffered from constant pain in the sacral region and the tenesmus was so distressing that he was transferred to the surgical wards and inguinal colotomy was performed to lessen his sufferings. He died two or three weeks later on Dec. 21st.

Necropsy.—The stomach appeared to be "trifid." On laying it open, however, it was found that the appearance was caused by a polypoid growth involving and distending the parts in the region of the pylorus. With regard to the rectum and the anus, there was a mass of growth (ulcerating) at the lower end of the rectum involving the anal mucous membrane and the skin about the anus. There was another growth constricting the gut just below the colotomy wound. The mucous membrane between these growths presented a curious polypoid appearance. Otherwise the intestines were normal. The liver weighed 12 pounds. There were weak adhesions to structures in the neighbourhood. The surface showed several large umbilicated growths of a cream colour. On section almost the whole of the liver was seen to be occupied by large masses of secondary growths uniformly distributed. The gall-bladder was normal. The pancreas, the spleen, the kidneys, and the thoracic viscera were normal.

The microscopical examination of the different tumours may be briefly stated. The stomach growth was an adenoma. There was an overgrowth of glandular tissue but the arrangement was regular and nowhere showed any tendency to invade the muscular layer. The polypoid projections on the rectal mucous membrane were also adenomatous in character; in some places the glandular cells showed a disposition to proliferate. Both here and in the stomach there was evidence of inflammatory infiltration. Both upper and lower rectal growths were columnar carcinomata. The secondary growths in the liver were also columnar carcinoma.

Remarks by Mr. LAWFORD KNAGGS and Dr. O. C. GRUNER.—It has been already stated that the polypoid condition of the rectum was limited to the tract between the two growths and that the mucous membrane was healthy above the upper one. This fact would seem to point to the development of the "polyposis" subsequently to the formation of the upper growth. And if this inference is correct the altered condition of the mucous membrane was due to influences introduced by that growth. At the anal extremity of the rectum the polypoid mucous membrane gave place to another carcinomatous tumour. Which of the two malignant growths was the first to make its appearance? The microscopic appearances are if anything rather in favour of regarding the upper one as the older of the two; the fact we have alluded to in connexion with the limitation of the polyposis would tend to confirm this view. Further assistance may be derived from the probable origin of the anal growth. It is impossible not to associate that origin with the polypoid state of the mucous membrane. Where the irritation is naturally greatest—viz., at the anus—the pro- [illegible] ılar layer [illegible] ·ction can [illegible] he actual [illegible] be determined. The growth is too extensive.

What was the cause of the polyposis? Irritation or passive congestion? The only form of irritation that suggests itself [illegible] until they [illegible] ı the cause [illegible] ıre also to have been affected. On the other hand, passive congestion was not unlikely to be produced by the constriction of the [illegible] nphatics in the [illegible] -mortem obser- [illegible] ımour is clear. It cannot, therefore be regarded as a secondary or metastatic growth. But it is [illegible] hronic inflammation and it is sit[illegible] ..ere malignant disease most commonly occurs. Of the goal towards which it was tending there can be little doubt when the conditions connected with the anal growth are borne in mind. The term "pre-cancerous" may be fairly applied to it. The only possible connexion that it may have had with the rectal growth is through the dyspepsia which obstruction may have caused. We are unable to express an opinion as to whether the secondary growths in the liver were derived from one or both rectal growths.

Finally, our conclusions may be stated as follows: (1) There existed a tendency to cell proliferation and hypertrophy in parts of the gastro-intestinal tract when inflammation was excited; (2) the stomach growth was a direct result of this tendency and was not malignant; (3) the upper rectal growth was probably the primary disease; (4) the polypoid state of the rectum was in some [illegible] pendent of the upper growth and in no sense a "secondary" or metastatic tumour); and (6) the liver deposits were secondary to one or both of the rectal growths.

Microscopic report by Dr. GRUNER. — 1. The stomach. The polypoid condition was preceded by a rather œdematous condition of the gastric mucous membrane with some round-celled infiltration around the orifices of the glands. Near the hypertrophic portion the round cells became very abundant and there were even small accumulations like minute abscesses here and there in the submucosa. The polypoid [illegible] by shrun[illegible] was conti[illegible] the least tendency to ingrowth into muscular tissue. 2. The polypoid rectal mucous membrane. This consisted of [illegible] the glands—namely, proliferative processes in the former [illegible] the mucous membrane was traced from above towards the growth the glandular elements were seen progressively to increase their proliferative tendencies until at the seat of growth the gland acini were actually embedded in groups of muscle fibres constituting true columnar-celled carcinoma. The cells lining these glands were more cubical in shape than were those lining the glands of the mucous membrane above and they did not show excess of mucin. Where the proliferation of mucous membrane was commencing there was definite evidence of inflammation in the interglandular connective tissue. 4. Upper rectal growth. The mucous membrane in the immediate vicinity of this growth was much more œdematous than that in the lower growth, the glandular elements being widely separated by a very loose connective tissue in which there was great accumulation of leucocytes. This inflammation extended no deeper into the intestinal walls than the mucous coat, and the outskirts of the growth had merely the aspect of overgrown glands without any tendency to invasion of tissue. This portion of the tissue passed continuously but rapidly into true columnar celled carcinoma. The gland spaces in this growth were large, in marked contrast to those in the lower growth. The cavities were filled with mucoid material and the lining cells were distorted, presumably from the overproduction of mucin. The portions in the deepest parts of the growth showed tracts of dead cells amongst the carcinoma acini. There was not much fibrous tissue around the growth. 5. The liver. The liver substance in the neighbourhood of the secondary growths was profoundly altered. The vessels were surcharged with blood, the liver trabeculæ were attenuated, and the cells had lost their shape for some considerable distance away from the growth. There was, however, little cellular exudate from the vessels. The growth had the characters of a columnar-celled carcinoma resembling the rectal growths but not showing such large spaces as were seen in the upper one of the two. The cells were, however, much shrunken and the interstitial tissue was very loose. It would be impossible to state whether the secondary growths in the liver arose from one rectal growth more than the other but the stage of growth which each of the three growths presented showed that the secondary growths (the last to appear) were more like the lower rectal growth, which would thus be more recent in origin than the upper one (the gland spaces of which had become much larger and showed degenerative processes).

POLICE HOSPITAL, BANGKOK, SIAM.

A CASE OF LIGATURE OF THE LEFT SUBCLAVIAN ARTERY.

(Under the care of Dr. H. CAMPBELL HIGHET.)

THE patient in this case was a young man, a Siamese, who was admitted into the Police Hospital, Bangkok, Siam, in August with a fishing trident firmly embedded in the muscles around the front of the left shoulder. Mr. E. A. Bryan, the hospital assistant, finding that the prongs of the trident were too firmly fixed to be easily removed, administered chloroform and with much difficulty and some enlargement of the wounds extracted the weapon. This proved to consist of three prongs, each four and a half inches long, three-sixteenths of an inch in diameter, and furnished at about an inch from the point with a strong barb one quarter of an inch long. The three points formed an equilateral triangle, each point being one and a half inches from its neighbour. The wounds were two and a half inches deep. As the trident was in a highly septic condition when it was thrust into the man's shoulder, and as it had been embedded there for over two days, it is not surprising that all the wounds were suppurating and that the arm and shoulder were much swollen and reddened. After some days' treatment the cellulitis seemed to improve but 11 days after admission hæmorrhage commenced and could not be controlled by plugging. On the night of August 30th the wound from which most blood was exuding was therefore enlarged and an attempt was made to tie the axillary artery in its third part. This was found to be impossible owing to the fact that a large portion of the artery was in a sloughing condition. The left subclavian artery was then tied in its third part; the operation being rendered somewhat difficult as the assistant had to maintain direct pressure on the bleeding point and so the shoulder could not be depressed. Three days after the operation a herpetiform eruption appeared on the left loin and on the right shoulder and upper arm accompanied by considerable fever and an icteric appearance of the skin and conjunctiva. The fluid from the vesicles was examined and found to be sterile. The man left the hospital practically well and was seen again by Dr. Highet two months later when the following note was made: "Seen at the Criminal Court to-day. Is well and strong; all wounds cicatrised; humeral and radial pulse imperceptible; movements of shoulder-joint very good; arm rather thinner than right arm but not markedly so."

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Annual Meeting.

THE annual meeting of this society was held on March 1st, Sir R. DOUGLAS POWELL, the President, being in the chair.—The annual report showed that the financial condition of the society was extremely satisfactory but that the attendance at the meetings of the society left something to be desired. With a view to improve this it had been decided by the council to print abstracts of papers in advance and to send them with formal invitations to persons named by the authors. During each session at least one special discussion would be arranged. The President's address in connexion with the centenary of the society would be delivered on May 22nd and the Marshall Hall prizeman, Dr. Henry Head, F.R.S., would give an address on Afferent Nerves under a New Aspect on May 23rd. A banquet would be held on May 22nd at the Hotel Cecil, at which the society would entertain His Royal Highness the Prince of Wales and other distinguished guests. A conversazione would be held on the night of May 24th and during the week there would be an exhibition illustrating medical matters of 100 years ago.

The HONORARY LIBRARIANS announced that a card catalogue of the books in the library had been completed.

The PRESIDENT gave the Annual Address, in the course of which obituary reference was made to those Fellows of the society who had died during the last year. In discussing the work of the society the question of a possible amalgamation of the various metropolitan medical societies was raised and the advantages accruing from such a scheme in the way of economising time and money were clearly emphasised.—Dr. J. E. POLLOCK proposed, and Sir WILLIAM H. BROADBENT seconded, a vote of thanks to the President for his address and supported the idea of initiating an amalgamation of the societies.—Sir THOMAS SMITH proposed that the council of the society should be requested, with as little delay as possible, to invite the leading medical societies of London to arrange for a joint meeting for the purpose of considering the advisability of amalgamating and to take the necessary preliminary steps for that purpose.—The motion was seconded by Mr. D. H. GOODSALL and unanimously carried.

Sir W. H. Broadbent and Dr. T. Buzzard were elected new vice-presidents of the society. Dr. Howard H. Tooth, Dr. Dawson Williams, Mr. Clinton T. Dent, Mr. A. Marmaduke Sheild, and Mr. Thomas Wakley, jun., were elected new members of the council.

Discussion on the Subsequent Course and Later History of Cases operated on for Appendicitis.

An adjourned meeting of the society was held on March 7th, Sir R. DOUGLAS POWELL, the President, being in the chair.

The PRESIDENT resumed the discussion on the Subsequent Course and Later History of Cases operated on for Appendicitis. He said that he had nothing to add to the subject of absence of relief after operation in cases of appendicitis. He had met with pulmonary embolism many times in the sequel of injuries and of surgical operations and, without giving actual numbers, he felt sure that it had been more frequent in his experience after operations *for appendicitis than after other operations.* Although this complication did not appear from the statistics to be very common it was probable that many of the cases of pleural effusion and dry pleurisy occurring after operation were due really to pulmonary infarction. In Oppenheimer's series 16 per cent. of the acute cases developed pulmonary embolism. With a view to prevent this complication it was advisable in the chronic cases to keep the patient in bed for a few days before operation, to order a simple diet, and to give small doses of calomel as an intestinal antiseptic An interesting case of secondary pulmonary infarction which had become tuberculous occurring some months after an operation for appendicitis had been observed in consultation with Mr. Charles Hartley and the patient was now progressing satisfactorily abroad.

Dr. H. P. HAWKINS drew attention to the fact that in spite of increased earliness of operation the mortality from appendicitis showed no fall and in some cases a slight rise as compared with a period of ten years ago. He accounted for this by a gradual rise in the severity of the disease which was occurring *pari passu* with its increased frequency. He agreed that a great reduction in the mortality was to be anticipated by continual insistence on early operation. As regards imperfect relief or recurrence of symptoms after excision he thought cases were few. Putting on one side cases where confusion occurred between appendicitis, floating kidney, and renal and biliary colic (the occasional difficulty of differential diagnosis being allowed), he believed that the rest of the cases of imperfect relief should be attributed to a colon neurosis. Of this group mucous colitis, a non-inflammatory motor and secretory neurosis, was the best known example, but it shaded off into minor grades of pure enterospasm of which a clinical description could be given. In all degrees of the neurosis, if the trouble occurred in the ascending colon with attendant neurasthenia and secondary hypochondriasis the appendix could be excised without necessarily giving relief.

Sir WILLIAM H. BENNETT believed that the real value of statistics lay in their relative rather than their absolute application and that those derived from hospital practice presented a gloomier picture than the truth. In cases of appendicular abscess it was not desirable to attempt to remove the appendix for the sake of making sure that the origin of the disease was destroyed. He had never regretted leaving the appendix in such cases but he had on more than one occasion regretted making the attempt to remove it Complications often arose from inadequate operations in simple cases of appendicitis and the practice of leaving a stump was, in his opinion, often a source of after trouble. The fact that a stone in the right ureter might give rise to symptoms suggesting appendicitis was illustrated by a case in which a healthy appendix was found but in which a ureteral calculus was discovered at the operation and passed four days later per urethram. It was advisable to submit doubtful cases to examination by the x rays for the purpose of excluding this source of error. No prolonged pain in the scar was ever met with if a rule was made never to apply a ligature through the undivided peritoneum. Recurrence of symptoms had been present in three cases, in all of which a history of malaria, and in two of which a history of dysentery, had been noted. Fæcal fistulæ occurred in 5 per cent. of cases but many of these healed very quickly and would be better regarded as temporary fæcal discharges rather than true fistulæ.

Mr. C. B. LOCKWOOD stated that the main object of the discussion was to learn what happened to those patients who had had the appendix removed. It was clear that the method of proceeding by clinical statistics alone was incomplete and fallacious, mainly because so many possibilities were ignored and so much was omitted. The future of the patient must in a large measure depend upon the disease which existed in the appendix at the time of its removal. For instance, some were tuberculous, some were cancerous, and some were actinomycotic. Correct conclusions could not be arrived at by examining the appendix with the naked eye and in a scientific inquiry clinical evidence should be supported by microscopical and, if possible, by bacteriological examination. Some of these requirements had been fulfilled in the synopsis of 200 cases of his own which he had provided. In a case of primary columnar-celled carcinoma of the appendix *the disease was unrecognisable by the naked* eye and although the cæcum and the end of the ileum were removed the disease continued to grow slowly in the pelvic glands and ultimately proved fatal. A section of the ordinary type of carcinoma of the appendix had been given to him by Mr. W. McAdam Eccles who said that on removal the nodule was thought to be tuberculous. If appendices were systematically examined probably 1 in 250 would prove to be cancerous. Only four instances of tuberculous disease of the appendix occurred in the *200 cases but the prognosis of this condition* was unfavourable. The question of removing the appendix after an appendicular abscess had been evacuated should be decided in each case on its merits, but as a general rule that course should be adopted if the general and local conditions did not forbid it. The commonest disease of the appendix was ulceration of the mucosa with penetration of bacteria into the tissues of the mucosa and into the lymphatics and onwards through the hiatus muscularis into the peritoneum. The ulceration was associated with septic, muco-purulent, or fæcal contents and the latter with concretion in 23 out of 200 cases. Reference was made to two cases of mesenteric thrombosis in patients suffering from acute intestinal obstruction. Among the causes of recurrences of appendicular symptoms was the presence of enormous dilatation of the cæcum with fæces which could be readily treated by means of enemata and care in diet.

Mr. W. H. BATTLE referred to five cases in which there was a return of symptoms after an abscess had been evacuated with success. In all of these the appendices were removed later and showed marked pathological changes. In five other cases a secondary abscess formed, the appendix not having been removed at the first operation. Sinus formation occurred in six cases after a localised abscess had been opened and drained. In two other cases operation was performed for commencing peritonitis where there had been previous localised suppuration. The appendix had been removed in seven cases after an abscess had been evacuated and all inflammatory symptoms had subsided. In several of these cases concretions were found and in all these were evidences of pathological conditions which might give rise to further trouble. Similar conditions were found in the appendices removed after evacuation of the abscess into the lower part of the bowe[illegible] sfully extirpated in seven [illegible] was present but in one of [illegible] from a cardiac seizure four days after the operation. The condition of the appendix was also described in several cases which had died from general peritonitis or from some other cause which was *not fully explained by the post-mortem examination.* In conclusion, early evacuation of an abscess and secondary removal of the appendix were advocated in the majority of cases and the removal of a concretion at the first operation was not considered an indication for believing that the patient would be free from recurrence of symptoms.

Mr. GEORGE R. TURNER preferred to operate on all acute cases as early as possible unless they were obviously [illegible] nortality was 10 in 125 and [illegible] s were obtained in patients [illegible] ack. Operation during the [illegible] ility of 0·5 per cent. in the combined statistics of five hospitals; in all other cases the combined statistics showed a death-rate of 23 per cent. A great reduction of fatal results would be produced by operating at an early period in the disease and at the same time complications and unfavourable sequelæ would also be much reduced in numbers. The method of opening the abdomen by separation of muscular fibres was justifiable in simple cases but was inadequate when pelvic complications had to be dealt with.

Mr. H. F. WATERHOUSE referred to the fact that although appendicitis was three times more common in the male than in the female sex complications were infinitely more frequent in women. The appendix should be removed flush with the cæcum and the absence of this precaution was responsible for recurrent trouble in some cases. Ventral hernia did not occur when [illegible] incised —a method [illegible] had empha[illegible] right ovary and tube at the time of operation. Pyonephrotic kidneys and ureteral calculi were possible sources of errors in diagnosis. Early operation was a very important factor in reducing the mortality of the disease and in 19 cases which had been operated on within 24 hours of the onset of symptoms *there had been no deaths in* spite of the fact that perforation had been present in three instances. The appendix should not be removed when evacuating an abscess.

Mr. J. P. LOCKHART MUMMERY emphasised the importance of care in the after-treatment of operation cases.

The discussion was then adjourned until the next ordinary meeting of the society.

OBSTETRICAL SOCIETY OF LONDON.

Chyluria complicating Pregnancy.—Pregnancy in a Rudimentary Uterine Cornu.—"Grape-like" Sarcoma of the Cervix Uteri.

A MEETING of this society was held on March 1st, Dr. W. R. DAKIN, the President, being in the chair.

Captain J. C. HOLDICH LEICESTER, I.M.S., read a short communication on a case of Chyluria in a Eurasian, 18 years of age. She had been married eight months and had advanced to the eighth month in pregnancy. She presented herself for treatment at the Eden Hospital for Women, Calcutta, on account of severe pain on micturition. The urine had become milky for the first time on the previous day. For five months she had had a swelling in the right thigh which had occasionally given rise to pain. The swelling felt like an enlarged gland in the femoral ring; it quickly subsided. On examining the urine drawn by catheter it was milky-white in colour with a faint pink tint and contained some white sediment; it had a specific gravity of 1022 and was *faintly acid; the albumin amounted* to one-quarter. Traces of blood and chyle were present. Phosphates were in excess. On microscopical examination, besides phosphates and oxalates and blood corpuscles, bladder epithelium and several filaria embryos were found. The urine was found to clot shortly after being passed but soon broke down again and remained fluid. Both the labour and the puerperium passed naturally except for a rise of temperature to 101·8° F. on the sixth day after delivery. The urine as a rule continued to preserve its milkiness. *The blood* was examined *on three separate* occasions and on each was found to be swarming with filaria embryos. The case resisted all treatment, whether of diet, drugs, or posture, and the condition of the urine remained practically the same throughout. The patient's general condition showed considerable improvement during the time she was in hospital. In Captain Leicester's opinion there was little doubt that in this case the pregnancy was the exciting cause of the chyluria, which was due to the disturbance of the pelvic lymphatics which had been previously affected by filarial obstruction of the thoracic duct.

Dr A. H. N. LEWERS related a case of Pregnancy in a Rudimentary Uterine Cornu in which he had operated for severe internal hæmorrhage. The patient was 24 years of age and had been married 13 months. She had had a miscarriage at about the sixth month of pregnancy six months after marriage. One menstrual period had occurred 13 weeks after the miscarriage. On the day prior to her admission to the London Hospital she was suddenly taken ill with severe pain in the abdomen. Preparations were at once made for operation. The patient's condition was so bad that both rectal and intravenous saline injections and hypodermic injections of strychnine were resorted to. On opening the abdomen the ovum was discovered on the left side. The sac burst on handling and a fœtus of at least three months gestation escaped with the liquor amnii. The pedicle was found to be much thicker than in a tubal gestation; it was transfixed and tied a second time to render it secure. On subsequent examination the wall of the sac proved to consist of muscular tissue, about half an inch in thickness, formed by the rudimentary horn on the left side. It was noted that the left *ovary did not contain* the corpus luteum, from which Dr. Lewers inferred that external migration of the ovum from the opposite ovary had occurred. The patient passed a decidual cast eight days after the operation and made a good recovery.

Dr. HERBERT WILLIAMSON showed a specimen of "Grape-like" Sarcoma of the Cervix. He remarked upon the rarity of this form of sarcoma of the cervix, only 16 cases having been previously recorded. The specimen (which was removed by operation from a woman 39 years of age) consisted of a firm central core to which were attached a number of branching processes. These processes here and there throughout their length were dilated into cyst-like bodies of the size of cherries. Microscopically the growth was a mixed-celled sarcoma; the cysts were covered on the surface by several layers of stratified squamous epithelium and their fluid contents appeared to have accumulated as the result of œdematous infiltration rather than of myxomatous degeneration of tissues.—Dr. M. HANDFIELD-JONES brought forward the history of a case in which sarcoma of the same type had been found springing from the whole lining membrane of the body of the womb. In his own experience the disease had shown very little evidence of malignancy and the patient's life had been prolonged for several years after the disease was first recognised.

The PRESIDENT delivered his inaugural address.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The Etiology of Carcinoma.

A MEETING of this society was held on March 1st, Professor JOHN CHIENE, the President, being in the chair.

Dr. GEORGE THOMAS BEATSON (Glasgow) read a communication on the Etiology of Carcinoma. He said that recently various authors had strongly endorsed the view that in carcinoma they had to deal with a microbic disease. He referred chiefly to the researches of Professor Doyen of Paris and of Dr. W. Ford Robertson and Mr. Henry Wade of Edinburgh and stated that so far apparently as they went they did not fulfil the postulates laid down by Koch. There was yet wanting in connexion with them the crucial test of the reproduction of carcinoma in animals by means of the respective micro-organisms and this was almost an essential for the establishment of the position which these authors took up. If it were true that Professor Doyen's serum had a curative effect in carcinoma it formed a most convincing evidence in favour of his theory. He had been most impressed in the communications he had read on the effects produced by Doyen's serum by the absence of any evidence of changes in the cancer cells themselves. Great stress was laid on the mobility that it induced in the growth. This was what might be expected to result when the source of the serum was considered and the conditions which were usually present in cancerous growths. The presence of generally an extensive area of small cell infiltration was one of the most constant features of such growths. This infiltration was inflammatory in its nature and formed the factor that served in many instances to fix down the growth to the surrounding tissues. The presence of this condition was not considered by surgeons as a favourable condition for operation as it seemed to be associated with a tendency to recurrence. It was not unreasonable to hold that a serum made from microbic tissue (as Doyen's was) should have an effect on this inflammatory area as was seen in other instances of serum-therapy. This would allow of an operation being done which otherwise might be contra-indicated. If this were so such a serum would be of great value and its future rôle might be as an adjunct to operative treatment, being used as a preliminary to localise the tumour and to lessen the tendency to dissemination of the cell growth. Assuming that the parasitic theory of carcinoma had not yet been established Dr. Beatson was entitled to bring forward certain views that he had formed either as the result of experimental or clinical observations. The more he worked at carcinoma clinically the more he was inclined to regard it as a tissue vice and the more he leaned to the views which he had put before the society nine years ago and which he might designate as "*the germinal theory of cancer.*" He then stated that cancer consisted in the epithelium of the part affected taking on the active proliferation which was the marked characteristic of the germinal epithelium and that the special cells seen in sections of cancer (cancer bodies) would eventually be shown to be special ova or germinal cells. After alluding to the beneficial effects on mammary carcinoma induced by removal of the tubes and ovaries, the nature of the change consisting in a great increase in the stroma of the growth and a marked disappearance and fatty degeneration of the epithelial cells—an atrophic condition being induced, Dr. Beatson stated that it was on these grounds that he had based his germinal theory. To establish it on a scientific and trustworthy basis, however, they ought to find (1) nuclear protrusions (polar bodies) and (2) fewer chromosomes in the so-called germinal cells. In certain films from carcinomatous tissue made by Mr. Ernest G. Fortune there were appearances in certain of the cells containing the so-called parasite which indicated a body (stained green) either leaving or just entering the cells. In some cases it was surrounded by a distinct vacuole but it was not absolutely clear whether this was an extrusion or intrusion of a possible leucocyte and so no actual proof of the formation of polar bodies was established. Cancer cells which were dividing and undergoing mitosis showed a clearer appearance than the other, as if the process of division had some clarifying effect on the whole protoplasm of the cell. Mr. Fortune had also observed that while in the films made from cancer tissue cells could be found in all stages of karyokinesis, the cells containing the alleged parasite had never been seen dividing, though the cancer cells in their vicinity were doing so. Dr. Beatson drew attention to the work done by Professor J. B. Farmer, Mr. J. E. S. Moore, and Mr. C. E. Walker, in which they showed that the division of the nucleus of malignant cells very closely resembled that found in developing reproductive tissue. He drew attention to the marked *cellular* character of carcinoma, which was always regarded as made up of (*a*) epithelial cells and (*b*) connective tissue stroma. Its characteristic feature, however, was the disorderly distribution of its large, irregular, and polymorphic cells. The stroma was derived from the connective tissue spaces into which they were forced and they had no blood-vessels, nerves, or lymphatics of their own. Cancer cells simply lay in an intercellular fluid unpermeated by any newly formed blood-vessels. A cancerous tumour was composed of cells only, its stroma being a pre-existent element into which the cells had been forced by pressure. In such a tumour there was only a massing together of cells which had no tendency to develop into permanent tissue and so were entirely devoid of organisation. Cells so situated were of low vitality and were liable to decay, a characteristic which specially marked carcinomatous swellings (e.g., malignant ulcers). Another characteristic of the cancer cell lay in its *unirritating* nature. When cast off from the primary tumour and arrested in a distant part no local disturbance took place or constitutional derangement. Small local foci of dissemination in the lungs or the liver were often not revealed by any physical signs or symptoms. This had always seemed to Dr. Beatson a strong point in favour of the view that the carcinomatous cell was one which was the offspring of the body tissues and was in no way a stranger to them. Were this not so they ought to have in both primary and secondary tumours that disturbance of nutrition known as inflammation and this was generally observed in microbic or protozoal infections. The delay often found in seeking medical advice was frequently unavoidable. He was thoroughly opposed to the teaching that the general public should be instructed in the early symptoms and manifestations of carcinoma. The apprehensive frame of mind thus induced Dr. Beatson regarded as a powerful predisposing cause of the very condition which they wished to avoid. He alluded to the general good health which was so frequently associated with carcinomatous disease. The very pigmented condition of the fat in some of these cases had also attracted his attention. It presented a reddish-yellow (yelk of egg) appearance and had a colouring matter present which was not found in ordinary fat. This might also be associated with the lemon-tinged cachexia often seen in cancerous patients. He had also noticed while operating on cases of mammary cancer that the fat was in an oily and fluid condition and it was a general experience that in such cases carcinoma disseminated itself more rapidly than in those of spare build. As regards the source of the procreative fluid of the human body the ovaries and testes prepared certain modified epithelial cells (ova and spermatozoa), by the union of which the human embryo was produced. Maturation had first, however, to be accomplished and in the case of the ova and spermatozoa a series of cell divisions took place by which in each case there was a reduction of half the number of their chromosomes. In both these organs this process was accomplished by great cellular activity and the question arose, What was the stimulus which set it in motion so that in the ovum they had the polar bodies extruded and the reducing division in spermatozoa? It must be a secretion of some kind and it might be elaborated by the testes and ovaries themselves or by all the tissues of the body. In the latter case the testes and ovaries were merely instrumental in elaborating the work done by the rest of the body. The fluid portion of the seminal fluid, largely produced by the seminal vesicles, prostate, and Cowper's glands, was not only essential to the motility of the spermatozoa but also to their fertilising power. Again, removal of tubes and ovaries led to an increased deposit of fat in the body as if some secretion were being stored up and was no longer being removed from the tissues (as mucin accumulates in myxœdema). If this theory were correct there was a secretion which had to be reckoned with which not only bestowed vigour on the tissues themselves and which might even in certain circumstances confer on them a proliferating power but which seemed to have a special affinity for one particular tissue—viz., the fat. In this latter it might be retained and kept as a reserve, as when functional activity on the part of the ovaries and testes did not utilise it. It was generally stated that a tumour in the human body performed no physiological function and in carcinoma the cells had been likened to an invading host advancing to the conquest and eventual destruction of every tissue in the body. The more, however, that Dr. Beatson had thought over the subject the more he felt that the so-called autonomous proliferation of cells was a mere assumption and that possibly carcinomata were doing work for the organism by eliminating or dealing with some body product. If so this would bring them into line with the other body cells and presented them not as rebels but as taking up some new [illegible] duties of other cells no longer [illegible] ground for such a view be [illegible] shape of rounded bulbs or nodules in the roots of healthy bean and clover plants bore, Dr. Beatson thought, on the work of Dr. Robertson and Mr. Wade. These growths varied in size from a small pin-head up to a fair-sized potato and occurred on the healthiest plants. These nodules were packed with nitrifying organisms which absorbed nitrogen from the air and supplied their hosts, the plants, with the only food they required. The healthier the plant was the greater was the number of these nodules. Dr. George Moore of Washington grew these bacteria and packets of them were now made up and sold commercially to inoculate the ground. The result is that crops on soil so treated have increased a hundredfold, thus making the barren places to rejoice. Paget long ago drew attention to the [illegible] case of carcinomata he thought there were indications that this was so and this seemed to be confirmed by Farmer, Moore, and Walker, who found that there existed in malignant growths special cells which were characterised by a reduced number of chromosomes and which had their prototype in the reproductive cells of the body. Thus in functional inactivity or diseases of the testis or the ovary the part affected by the carcinoma did vicariously their work or helped them in an excess of work thrown upon them. If the procreative fluid were elaborated in the body tissues the possibility of this interchange was not unreasonable. The absence of organisation in the crowds of cancer cells of the tumour would suggest that they were *cast-off cells* which, were they not shut in by the tissues, would escape, as did those in the testes by the vasa deferentia. There were enacted in the tissues of the tumour the same cell activity and proliferation which went on in the testis and the ovary. Some of the neoplasms were glandular in character. Another point which had some bearing on the question of cancer as a secreting organ lay in the effects of operations for carcinoma. It was a very general experience that after removal of the tumour patients often put on flesh, cachectic signs might disappear. This was not easily explained unless the removal of the carcinoma had put a stop to something which was draining the tissues and markedly modifying them. Did the putting on of fat point to the fatty tissue of the body again taking on storage property to deal with a secretion which was no longer being used up by the carcinoma? If this were so, and Dr. Beatson inclined to the view, then the fat of the body bore some relation to carcinoma both previously to the onset of that disease and after its successful removal by operation. Under both conditions it had a salutary influence and it might be that only when its storage power was weak the more specially developed though degenerate cells of any body organ or tissue might draw upon the body secretion that the fat contained and by dealing with it in a different way manufactured it into an epithelial secretion on the lines of the normal reproductive tissue of the body. The beneficial results of oöphorectomy might result not only from a lessening in the amount of Dr. Beatson's suggested body secretion but also by adding to the capacity for fat development. In conclusion, Dr. Beatson said that the germinal theory of carcinoma harmonised most with the facts and course of the disease though it assumed the existence of a general tissue secretion. In the event of the testis or the ovary being unable to deal with this procreative fluid through decay or disease, and the fat of the body having no special capacity for storing it, it was probable that tissues or organs which had retrograded physiologically might take upon themselves the function of secreting it. If this were correct then in carcinoma they had a tissue secretion to deal with in relation to which the fat of the body probably acted as a middleman. This being so Dr. Beatson thought they should not take too pessimistic a view of the therapeutic position in connexion with the disease or despair altogether of its successful treatment.

In the discussion which followed Mr. **Harold J. Stiles** said that they ought to look at carcinoma from the widest and from the most fundamental points of view and this was what Dr. Beatson had done, and his propositions were deserving of the most careful consideration. The starting point of a carcinoma was in the epithelial cell. The essence of the condition was the atypical uncontrolled proliferation of cells. In opposition to what had been said he affirmed that these cells did cause inflammatory proliferation and so fibrous tissue was produced. In a carcinomatous lymphatic gland distinct diapedesis from venules could be observed. What originated the starting process? This ought not to be studied in the mamma but in an exposed epithelium—e.g., ulcer of the tongue, or in the conversion of a chronic ulcer of the leg into a carcinomatous one. In such there was a proliferation of epithelium and this got into new surroundings. In the case of the ulcer the epithelium endeavoured to cross over and to cover the granulations, while at the same time there was a proliferation downwards at the edges of the ulcer and ultimately the deeper layers took on a deeper growth and thus a lymphatic infection ensued. Mr Stiles did not think that the testes or the ovaries had any part to play in the production of carcinoma, for this disease was found in every kind of individual, thin or fat, healthy or weakly. If malignant cells were decendants of epithelial cells they did not know what converted them into germinal cells and he doubted if they ever would find this out. The glandular appearance seen in certain cases of mammary carcinoma was simply due to the fact that epithelial cells endeavoured to perform their normal function. This could be best studied in those conditions which were on the border line between inflammatory breast tumours and real carcinoma. The most interesting condition was Paget's disease; here one found the malignant cell isolated in the midst of perfectly healthy epidermis. It looked very like the ova. Each proliferated and formed a cluster in the deeper layers of the epidermis. Where had they come from? If a section were made of the mammary duct as it passed through [illegible]

The [illegible] functio[illegible] also be [illegible] every malignant tumour was an excessive local reproduction. The migration was due entirely to want of food and the large cells in Paget's disease were migratory. Did the tumour arise because of an excessive amount of the maternal or of the paternal element? Under normal conditions there was a healthy balance between these and an [illegible] grew, or, in other words, [illegible]e ovaries this maternal [illegible] still hope for improve[illegible] the woman was past ovulation.

Dr. **William Russell** remarked that Dr. Beatson's argument was based upon observations showing that removal of the ovaries was useful in cases of mammary cancer. One had to remember, however, the close sympathetic relation between the pelvic organs and the mammæ in women. It was not claimed that this operation was equally useful in carcinoma of other parts and so he did not quite follow the drift of the argument. In the removal of the testes for enlargement of the prostate and of the ovaries in myomata the atrophic influences induced had to be remembered. The blood serum was the expression of the secretion from all cells in the body, so the serum must be modified by the removal of any important gland. This had been abundantly proved in the work on bacteriolysis, hæmolysis, and especially cytolysis. In the case of epithelioma of the lip the germinal view was that certain germ cells in the epithelium multiplied and so formed the tumour. Even if it were true that epithelioma of the lip began in two or three cells the mass of epithelioma took on a general proliferation and this process extended to adjoining columns of epithelium. He could not believe that any maternal plus process could cause this. It was very distinctly an infective process. This was further shown by the occurrence of metastases. A cell was carried by the blood or lymph stream and was arrested in some organ. In spite of all the protective properties of the cells around it the cell which ought to have been destroyed proceeded to multiply and not only so but cells in the new organ sometimes became cancerous. A malignant nodule on the surface of any abdominal organ, if it broke down and the débris escaped into the abdominal cavity, caused a general infection of the whole peritoneum. Dr. Russell hoped that before long it would be shown that carcinoma is caused by an external parasite which gains entrance and stimulates cellular reproduction.

Professor A. R. SIMPSON, Dr. P. MACBRIDE, Dr. W. TAYLOR, and Dr. JAMES RITCHIE also took part in the discussion and Dr. BEATSON replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

A New Plaster Apparatus for Fractured Femur.—Fracture of the Tibia.—Excision of Joints.

A MEETING of this section was held on Feb. 24th, Mr. E. H. BENNETT being in the chair.

Dr. W. I. DE COURCY WHEELER exhibited an Apparatus designed by himself to facilitate the application of plaster of Paris to fractures of the femur either as a primary dressing or at any period before union had taken place. It consisted essentially of two gates swung on an upright iron bar on which rested a padded crutch to receive the perineum. The machine was so arranged that accurate extension could be kept up during the entire operation of encasing the leg and the pelvis in plaster. At the same time (extension being applied by means of a clove hitch attached to the ankles and rollers surmounting the end of the gates) abduction and adduction could be made relatively equal and the errors arising from obliquity of the pelvis could be avoided. The amount of extension put on could also be estimated by two Salter's balances which intervened between the rollers at the end of the moveable gates and the clove hitch attached to the legs of the patient. Five or six cases had been treated on the apparatus with success. The ideal fractures were those near the middle of the shaft. Extension was put on until both legs were the same measured length, no errors being likely if the gates were open to the same extent; this latter measurement could be read off a graduated bar provided for the purpose. The plaster was rapidly rolled on and very free access to the limbs was obtained. Only one assistant was necessary. Special provision was made for the surrounding of the pelvis with the roller bandage and this could be done without any hoisting of the patient from the table by a simple manipulation of the apparatus. The apparatus was very simple, could be made by any ironmonger, and cost about £2. In suitable cases the injured limb was encased with the pelvis and also the sound limb as far as the knee-joint, leaving a strong wedge of plaster in the perineum. The patient was allowed to move about on crutches in a few days and frequently no shortening resulted.—Mr. BENNETT expressed the opinion that the apparatus was probably useful in general hospital work but could hardly be used by country practitioners.—Mr. R. F. TOBIN said that Mr. Wheeler's method would be useful in the treatment of fractures of the femur in field service.

Mr. BENNETT read a paper on Oblique Fracture of the Tibia. He said that fracture of the tibial shaft alone was rare as a result of indirect violence, although common enough when the violence acted on the bone directly. Oblique fractures of the central portion of the shaft without accompanying fractures of the fibula were rare. In a case which recently came under his notice the patient, a girl, aged 15 years, jumped from a height of about 12 feet on to the ground and immediately fell backwards. Although she was able to stand up she could not put any weight on the injured limb or attempt to walk. On being taken to hospital soon afterwards she was found to be suffering from pain and complained of loss of power in the limb but it was not possible to obtain crepitus or to detect any evidence of abnormal motion in the limb. An x ray examination, however, revealed the presence of a fracture. It was very oblique, traversing almost four inches of the shaft of the tibia in its middle segment. Its direction was from above, and without downwards and inwards. The progress of the case was uneventful and union was perfect in the ordinary time. The absence of deformity was explained by the integrity of the fibula. The skiagrams obtained from this case afforded the only example which he had seen of *oblique fracture of the shaft of the tibia only from indirect force.*—Dr. W. S. HAUGHTON said that in studying the long bones stereoscopically it was found that the oblique direction of the lamellæ was the rule and not the exception and that when fractures were regarded from the anatomical standpoint it could be seen that their planes ran parallel to the direction of these bone lamellæ.—The communication was also discussed by Mr. TOBIN, Mr. EDWARD H. TAYLOR, and Mr. G. JAMESON JOHNSTON.

Mr. KENNEDY read a paper on Some Cases of Joint Excision. One case of excision of the knee was remarkable as the joint was riddled with sinuses and had been fixed at a right angle for years; the patient also showed symptoms of well-marked pulmonary tuberculosis, a cavity being present in one lung. Nevertheless recovery quickly followed operation, the lung healed rapidly, and the patient was enabled to get about. In connexion with this case Mr. Kennedy dwelt on the importance of fixing the bones together after excision of the knee by Tobin's clamps or by suturing. A case of excision of the shoulder and one of excision of the elbow were quoted as examples of dry caries of the articular ends of bones. Although in each the disease had existed for years not a trace of suppuration was present in either. The diagnosis was difficult and was made clearer by skiagraphy.—Dr. HAUGHTON said that stereoscopy was of great value in diagnosing early tuberculosis of joints by means of the x rays. By its aid areas of rarefaction could be discerned and their true relations to each other and to the joint made out.

Mr. JOHNSTON exhibited a patient who had the power of voluntarily producing a partial dislocation of the knee.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in the medical school, Sheffield, on Feb. 17th, Dr. D. Lloyd Roberts, the President, being in the chair.—Dr. S. Buckley showed an example of Multiple Parovarian Cystic Disease together with Uterine Fibroid. The fibroid was enucleated and both appendages were removed as there was in close relationship to each ovary a cluster of small cysts of parovarian origin.—Mr. R. Favell showed a Dermoid of the Ovary as large as a seven months uterus which contained a well-developed mammary gland with a nipple as well as teeth and hair.—Dr. Sinclair White showed a similar specimen from a girl, aged 13 years, which was generally adherent and had a doubly twisted pedicle but had caused no symptoms.—Dr. Donald had removed an ovarian dermoid from a patient, aged 71 years.—Dr. A. Wallace showed three Uteri removed from patients, aged 50, 51, and 53 years, on account of hæmorrhage. Two were examples of cancer of the body, while the other had within the uterine wall a thickening layer composed of fibrous trabeculæ enmeshing muscular tissue. This uterus three weeks before operation was so large as to reach to the umbilicus. It was much less at the operation and was removed vaginally by means of vaginal incisions. Schuchardt's paravaginal incision was used in one of the other cases, while the abdominal route was chosen in one where the vagina was very narrow. Dr. Wallace had seen marked suppuration in Schuchardt's incision in several cases and had observed rapid recurrence of cancer in the scar.—These observations were confirmed by subsequent speakers.—Dr. Buckley men- [illegible] cyst of the outer part of one tube lined by granulation [illegible] Microscopic examination [illegible] chorionic structure.—Dr. [illegible] patient on whom he *operated for the relief of pain and hæmorrhage. A single soft* [illegible] Fibroid Tumour of the Uterus from the fundus of which a soft vascular red fan-shaped growth was springing. This was a spindle-celled sarcoma. The fibroid had been present for two [illegible] caused pain [illegible] ed the case [illegible] size in the lower uterine segment. She became pregnant and at the sixth month was very ill through pressure symptoms, jaundice, and albuminuria. The position of the fibroids excluded every measure short of hysterectomy. This was accordingly done, after which the symptoms rapidly disappeared.—Dr. J. E. Gemmell mentioned two cases of Primary Sarcoma of the Ovary in girls, aged 17 and 20 years. *These were remarkable for their rapid growth and extremely rapid recurrence in the form of soft generalised sarcoma of* the omentum and the mesentery.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on Feb. 22nd, Mr. W. B. Holderness, the President, being in the chair.—Mr. A. A. [illegible] ssion upon the subject [illegible] might be divided into [illegible] obstruction of the lumen [illegible] fæces, or bands; (2) inflammation without suppuration; (3) inflammation with abscess; (4) sloughing and peritonitis with sup- [illegible] no acute attack. The [illegible] transient and acute, the [illegible] ach disturbance, such as [illegible] children. Those in the [illegible] onset and were often preceded by nausea and abdominal discomfort. The pain was often all over the abdomen or more in the epigastrium. When general abdominal pain had subsided a lump was often to be felt and might remain long after the pain had gone. In the third class the onset was as in the second but often more severe. Occasionally a rigor was present. The pain and fever might persist after three days or the fever might [illegible] h day. [illegible] h day. [illegible] re was often a definite shock with the sudden onset. There was a low temperature with a rapid pulse which soon tended to become feeble. The pain was very acute at first but might decrease as the patient became more ill. Mr. Bowlby next detailed the treatment that he was in the habit of adopting in this disease. In all cases of sudden onset of pain apparently due to the appendix he would give morphine. No food should be given by the mouth, the patient being fed with enemata. He would continue the treatment by morphine and strychnine and apply fomentations locally. If the case belonged to Classes 1 or 2 the symptoms generally quickly improved and an operation for removal of the appendix might be undertaken in about three weeks or after a longer interval if the attack were more severe. He would avoid operation in the acute stage. In Class 3 as soon as the pus was localised he would open the abscess but would not search for the appendix. In these cases, however, he would still avoid early interference. In Class 4 he would operate at once and remove the appendix at the same time.—The discussion was continued by the President, Mr. J. W. Gooch, Mr. E. W. Adams, Dr. E. S. Norris, Mr. W. H. Beresford, Mr. J. O. Skevington, Dr. Wood, Dr. W. Wrangham, Dr. W. A. Ellison, and Dr. C. R. Elgood.

BURNLEY AND DISTRICT MEDICO-ETHICAL ASSOCIATION.—A meeting of this society was held on March 2nd, Dr. A. M. Sinclair being in the chair.—Dr. Thomas Snowball read a paper on Myopia in which he discussed various causes of the condition, including among others the performance of close eye work with defective illumination and stooping at eye work which tended to prevent the free return of venous blood. Myopia usually began in early school life and gradually increased. Bondi made an examination of 2000 school children and found that in the board schools (Volkschule) 4 per cent. were myopic, in the secondary schools (Burgerschule) 12 per cent., and *in the Obergymnasien 27 per cent.* Mr. C. H. Usher of Aberdeen, in an examination of the students at the *University of Aberdeen, found that 15 per cent. were myopic* and that the town-bred myopes were to the country-bred myopes in the proportion of 7 to 5. In the Report of the Royal Commission on School Training (Scotland) it was stated that girls were more myopic than boys and that the degrees of myopia increased with age up to 15 years. Dr. Snowball eventually discussed the formation of the myopic crescent and true posterior staphyloma, defective light sense, *diminished field of vision, and the causes for defective* central vision, especially that occurring in myopes between 40 and 50 years of age. He said that the complications of myopia included the black spot, the formation of cataract, opacities of the vitreous, displacement of the lens, thinning of the cornea, increase of intra-ocular pressure, and (most serious of all) detachment of the retina. He related instances of hereditary myopia which had occurred in his own experience and spoke of Head's observations with regard to local and referred pain in ordinary and progressive myopia. *There were two kinds of treatment—one by glasses and one by operation. In prescribing glasses some adopted* partial correction and some preferred full correction. Mr. Ernest Clarke recommended full correction and in cases of progressive myopia removal of the patient from school to open-air life in the country. Other preventive measures must be attended to, such as holding work well away from the eyes, avoidance of stooping, good illumination, and writing in an [illegible] be useful or operation was contra-indicated.—Dr. H. Edmondson corroborated Dr. Snowball's remarks about heredity in myopia and gave examples of it in several successive generations of cotton-weavers. He advocated the discission operation, as from his own cases and from cases about which he had inquired he found that over 50 per cent. were highly benefited.—Dr. J. S. Wilson and Dr. G. S. Pullon *also took part* in the discussion.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Feb 21st, Dr. T. Vincent Dickinson, the President, being in the chair.—Mr. J. Foster Palmer read a paper entitled "Pre-appendicectomy Appendicitis, its Bearing on Causation and Treatment." Referring to the largely increased numb [illegible] last few years [illegible] and "sixties," [illegible] period, the di [illegible] room. *Many of these cases, therefore, would have been* saved by modern treatment. In addition to the fatal cases *the nature of* which was thus discovered there must have been a number of others in which no diagnosis was made, besides a large proportion of milder cases which recovered. Taking, therefore, the number of recorded fatal cases as a kind of basis on which to form an approximate estimate of the total number of cases it would appear that about the end of the "fifties" and the beginning of the "sixties" there [illegible] appendicitis of [illegible] which had take [illegible] inference drawn was that the prevalence of the disease was not to be accounted for entirely by mechanical causes but that certain cyclical or quasi-epidemic influences might be at work which they did not at present fully understand. With regard to treatment it was only necessary to compare the post-mortem records of this earlier period with the results attained by modern surgery to be convinced of the great saving of life which had been brought about by their present methods.—Mr. C. Edward Wallis read a paper on Dental Caries, with lantern slides illustrating the pathological changes that [illegible] the opinion that to improve the [illegible] only be necessary [illegible] child's life but also [illegible] ng the period of pregnancy included in her dietary such calcium and other salts as would enable the teeth of her offspring to be properly calcified. Besides this, investigations had shown that breast-fed children possessed far better dentitions than those brought up on cow's milk and its many derivatives.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held at Birmingham on March 1st, Dr. E. W. Wood White, the President, being in the chair.—Dr. J. W. Russell showed a man, aged 29 years, suffering from Acromegaly.—Mr. L. P. Gamgee showed a man, aged 45 years, the subject of Adiposis Dolorosa. The disease had been in existence for five years and the patient had symmetrical masses of fatty tissue at the back of the neck, a mass in the right axilla, and a large one in the subcutaneous tissue of the abdominal wall. The tumours were softer and of less definite outline than ordinary lipomata, while those in the axilla and the abdominal wall were very tender on pressure. One of the tumours on the back of the neck was the seat of severe neuralgic pain. There was no abnormal pigmentation of the skin over the tumours and there had not been any subcutaneous hæmorrhages. The patient had for many years been a confirmed alcoholic. Attention was called to the fact that this disease very rarely occurred in males.—Dr. J. Jameson Evans showed an Eye which contained a Melanotic Sarcoma which had perforated the sclerotic near the corneal limbus. Before the eye was removed the large extra-ocular mass projected between the eyelids on to the patient's cheek. The following were the points of interest in the case: 1. The growth had arisen in an eye the sight of which had been destroyed by an injury from a piece of steel three years previously. 2. The symptoms before the growth perforated the globe were comparatively mild but its growth afterwards was exceedingly rapid. There was never any increased tension but there were a cystoid cicatrix at the site of subsequent perforation and some ciliary injection. According to the patient's statement the extra-ocular growth had only existed for three weeks. 3. The patient now (ten months after excision) was suffering from metastatic growths in the lung, liver, and in the skin of the face, chest, abdomen, and extremities. Dr. H. E. Utting of Walsall records that the number of growths on the surface exceeds 200.—Mr. J. W. Taylor read a paper on the Value of Colpotomy in the Thrombotic Form of Puerperal Fever (early thrombotic pyæmia).

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on March 2nd.—Dr. W. Hirst Bateman opened a discussion on Puerperal Pyrexia from the point of view of immediate treatment. It was important to decide (1) that the rise of temperature was connected with the puerperal condition and (2) to distinguish between sapræmia and septicæmia. Treatment should be (1) a calomel purge; (2) if the temperature did not fall within a few hours the uterus should be douched with perchloride of mercury; (3) a mixture of quinine and ergot should be given; (4) if the temperature remained high after two or three douches the uterus should be curetted, douched, and packed with iodoform gauze, the packing to be removed in five or six hours; and (5) antistreptococcic serum might be used.—Dr. S. B. Brentnall drew attention to the value of polyvalent serum.—Mr. G. W. Malim emphasised the importance of distinguishing between sapræmia and septicæmia. He doubted the advisability of curetting except in cases where there was retained membrane. Douching should be avoided altogether in real septicæmia.—Dr. W. E. Jameson spoke of the value of antistreptococcic serum.—Mr. S. T. Lord, Dr. J. Melvin, Mr. H. H. I. Hitchon, Mr. W. Pooley, Dr. J. G. Standing, and Dr. H. Harris also took part in the discussion.—Dr. Bateman showed a case of Acromegaly presenting the characteristic features. The feet were not markedly enlarged. There was complete atrophy of the left optic nerve and the right showed neuritis with temporal hemianopsia.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal West Kent Dispensary on March 3rd.—Dr. W. E. Pountney was elected an ordinary member of the society.—Dr. F. S. Toogood showed the following clinical cases: (1) Gout; (2) Tuberculous Wrist-joint; (3) Tuberculous Abscess of the Head; and (4) Phthisis.—Dr. R. D. Muir showed a case of Herpetiform Morphœa and a case of Multiple Fibroma.—Dr. R. E. Scholefield showed a case of Myxœdema and a case of Senile Chorea.—The cases were discussed by the members present.

Reviews and Notices of Books.

Museums, their History and Use. By DAVID MURRAY, LL.D., F.S.A. Glasgow: James MacLehose and Sons. 1904. In three Volumes. Total pages 1043. Price 32s. net.

VOLUMES II. and III. of this intersting work are composed of catalogues and bibliography, subjects which, although eminently important and useful, do not lend themselves to review. But Vol. I. comprises a history of museums that sets forth the ideas of a scholar and antiquary and a museum expert upon the right use of museums and these ideas merit the serious consideration of all those interested in education, whether as teachers, ratepayers, or philanthropists. Dr. Murray gives a delightful account of the very early museums, using the term to mean a collection of rarities. Passing over the ark and the collection of curiosities which, according to some authors, King Solomon had got together, he reminds us that in the Middle Ages the churches were the great storehouses of curiosities. Excluding relics, a common object to be seen in churches was an ostrich egg. These eggs may be seen any day at the present time in sundry Eastern churches and occasionally in those of the West. Durandus gave various mystical reasons for their presence but the most probable explanation is that they were regarded as a symbol of life. Their use was common in all branches of the church and almost universal in Mohammadan mosques. But from the very beginnings of "religion" the egg was regarded as a symbol of life and even in these days the Pace egg—i.e., the Easter egg—is still in use.

Dr. Murray says that the griffin's eggs, of which there were several in Durham Abbey, are believed to have been ostrich eggs. We can hardly agree with this theory for the ostrich egg was well known in mediæval times. Raine in his "St. Cuthbert" (Durham, 1828) gives a list of the treasures which were in Durham Abbey in 1383, and among them were nine griffin's eggs. He also suggests that they might have been ostrich eggs. One is said to have been ornamented and cut in two. Now Lethaby in his "Architecture, Mysticism, and Myth" points out that in at least one instance the griffin's egg is described as being hairy, of a brown colour, having a hard white and clear yelk. Nowadays we call them cocoa nuts. Carved ostrich eggs are fairly common but carved cocoa nuts are much more so and such nuts, whether carved or not, may well have filtered into England by way of Venice. Anyone who looks at Ruskin's drawing of the Lombard Griffin will see at once that it would lay an egg much more like a cocoa nut than that of an ostrich.

Other chapters of Dr. Murray's work treat of the Progress of Science, of the Beginnings of the British Museum, of Scottish Collectors and Museums, and of the Non-Scientific Character of Early Museums. Finally he ends with an admirable chapter on the Use of Museums. This chapter, as we have already said, merits the attention of all who are interested in education. Dr. Murray shows how valuable a well-arranged museum can be if used by a sensible teacher; a museum, he says, quoting Schelhammer, is a *bibliotheca sine libris* and it is just as important to provide objects for study as to provide books which tell about them. He has a poor opinion as to the use which is made of rate-supported libraries. On the other hand, he is rightly not satisfied with the way in which our museums are utilised. "Many of our museums do nothing but exhibit specimens; they make no provision for research and give no encouragement to systematic study. Our municipalities receive large sums of money from the State for educational purposes, but no municipality, so far as I am aware, has devoted any part of its funds for utilising its museums and publishing the results of research." Here we must take leave of what is certainly a most interesting work, one moreover which should, if its precepts are taken to heart, be of great use both to those who have money to give and to those to whom is intrusted the spending thereof.

Progressive Medicine. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital; assisted by H. R. M. LANDIS, M.D., Assistant Physician to the Medical Dispensary of the Jefferson Medical College Hospital. Vols. I. and II. 1904. Vol. I., pp. 337; Vol. II., pp. 334. Price 12*s*. each volume.

THE first contribution in Vol. I. is by Dr. C. N. Frazier. It gives a *résumé* of the progress recently made in the surgery of the head, the neck, and the thorax. Particularly interesting is the section on wounds of the heart. In *Progressive Medicine* for March, 1903, a table was published containing particulars of 39 cases of operations for closure of wounds of the heart. Since that time Dr. Frazier has been able to collect 21 cases, bringing the total number of recorded cases to 60. Of these 35, or 58 per cent., proved fatal and 25, or 42 per cent., recovered after operation. The absolute indications for operation after punctured wounds appear to be severe primary hæmorrhage and oppression of the heart's action from the accumulation of blood within the pericardium. In the case of gunshot wounds an expectant treatment should be carried out, inasmuch as many cases are known to have recovered spontaneously.

Under the heading of "Infectious Diseases, including Acute Rheumatism, Croupous Pneumonia, and Influenza," Dr. R. B. Preble reviews the work that has been accomplished by various observers in regard to diseases which have a bacterial origin. He considers that the questions most vigorously studied have been the unity or duality of human and bovine tuberculosis, the relation of cholera nostras and of sporadic dysentery to the Shiga-Flexner bacillus, and the nature and the frequency of paratyphoid infection. With regard to the last-named affection he regards it as being of the nature of a general infection. So far only three deaths have been recorded. In these cases on examining the intestines the Peyer's patches and the solitary follicles were found to be normal; but inasmuch as five cases of paratyphoid fever have been recorded in which intestinal hæmorrhage occurred it is probable that in some cases at least intestinal lesions exist. The fatal cases were all due to the "beta paratyphoid" bacillus. These pathological findings suggest that some of the reported cases of typhoid fever without intestinal lesions were really instances of paratyphoid instead of true typhoid infection. In relation to this subject we may draw the attention of our readers to a paper read before the Royal Academy of Medicine in Ireland by Dr. A. R. Parsons on Jan. 20th and reported in our columns on Feb. 18th, p. 430.

Dr. F. M. Crandall is responsible for the article on the Diseases of Children. He gives some interesting statistics bearing on the mortality of early life. After a careful consideration of the circumstances affecting infant life which obtain in various countries he quotes the opinion of Dr. Freeman who has made a special study of the subject in the United States. Dr. Freeman's conclusions are that the infant mortality of all countries is exceedingly high and this is shown to be unnecessary by the fact that infants who are well cared for show a very low mortality. The influences that contribute to the high mortality he believes to be defective feeding, "with heat, humidity, and bad surroundings as contributory causes." He states that there has been a marked decline in infant mortality during the past ten years in the United States, and especially in New York city, due for the most part to the decline in mortality from summer diarrhœa. He believes that the most important agency in reducing this mortality is the general adoption of pasteurising and sterilising milk for infant feeding. This method has been tried with success in some cities in this country.

In Vol. II. one of the most interesting communications is that by Dr. Alfred Stengel on Diseases of the Blood, Diathetic and Metabolic Diseases, and Diseases of the Spleen, Thyroid Gland, and Lymphatic System. An exhaustive account is given of Professor Bloch's views on pernicious anæmia. This observer insists that the term "progressive pernicious anæmia" fails properly to distinguish the disease from secondary anæmias which may run a pernicious course and suggests the name of "Biermer's progressive anæmia," under which are to be included only those cases the clinical course of which coincides with the features laid down by Professor Biermer. One of the most popular theories of the causation of pernicious anæmia is that it is due to a toxin formed within the intestinal tract, absorption of which brings about the hæmolysis believed to be the direct cause of the anæmia. Professor Bloch does not accept this view and offers the suggestion that "Biermer's progressive anæmia" is not an essential disease of the blood but can be traced to a primary asthenic composition of the blood-forming tissues. Further investigation is necessary before Professor Bloch's views can be accepted. We trust that the term "Biermer's progressive anæmia" will not be adopted. The association of an observer's name with a disease is, in our opinion, undesirable from several points of view. A name indicative of the pathological nature of the disease and the organ or the tissue of the body which it affects is more exact and more scientific.

These two volumes form a valuable addition to those that have preceded them.

Ex-Cathedrâ Essays on Insanity. By T. CLAYE SHAW, M.D. Lond., F.R.C.P. Lond. London: Adlard and Son. 1904. Pp. 250. Price 5*s*. net.

THESE *obiter dicta* deal mainly with subjects of a speculative kind and do not readily lend themselves to criticism. The following are amongst the topics dwelt upon: the nature of insanity, the symptoms of insanity, psychology and nervous diseases, surgery and insanity, and the treatment of insanity. The essay on the Nature of Insanity points out that that term means want of conformity with an artificial scale or standard which exists for each social level, there being no absolute universal standard. The author considers that there are numbers of persons in asylums who are much less affected mentally than are many in the outside world, who are lunatics by law alone, who ought to be restored to liberty but for the fact that they are unable to earn their own living and that the law is elastic. This view is somewhat disconcerting and likely to be misunderstood. That these persons cannot get their living argues that they are not *compos mentis.* Some such could, no doubt, be allowed out (boarded out) under guardianship. The mentally affected whom Dr. Shaw describes as at large at any rate mostly earn their living, do not run counter to the law, and are not under any social ban. The inmates of asylums who appear whilst there to be but little affected mentally have frequently an unpleasant way of showing their insanity when asylum control is removed. Referring to the germ theory of insanity, Dr. Shaw states that this must be admitted to be partially true and we agree that no more than this can at present be said. The author states his belief that in the insane the mucous membrane of the digestive tract undergoes ulceration as a result of trophic change. If this is a reference, as we presume, to the condition formerly known as ulcerative colitis but now commonly called asylum dysentery, we can only say that no valid evidence for such a belief is forthcoming. While it is open to anyone to speculate upon the trophic condition of the part affected it is incumbent upon all to recognise the rôle of the micro-organism in the production of these ulcerated conditions.

The author has some interesting remarks upon psycho-physics and their value, to which space does not allow us to refer. Referring to the subject of consciousness he mentions telepathy and second sight, and considers it ridiculous to deny that there are forms of matter visible and tangible to some few in view of existing well-authenticated instances. A chapter is devoted to the discussion of the symptoms of insanity; it is pointed out that undue prominence is given to mere forms of insanity (mania, melancholia, and so on) in text-books; these are "merely states of the same thing" with different degrees of reduction; the terms are convenient but connote nothing as regards causation, prognosis, and treatment. Dealing with the association between ideas and emotional states it is pointed out that in the insane ideas (delusions) frequently have not the emotional tone which normally they should have; thus persons expecting to be hanged show no fear and "emperors" will scrub the floor without sense of incongruity. Interesting speculation follows as to instances of the same separation of idea and emotional content in the sane. Reference is made to destructive acts, to the frequent commission of the suicidal act without consciousness, "and it is only when the brain is relieved from congestion (as in cut-throats and drowning attempts) that consciousness of the condition returns." This vascular interpretation of the rise and subsidence of impulsive states is hypothetical and dubious. In a chapter on Surgery and Insanity there is some highly speculative writing as to possible relationships between delusions and altered conditions and actions of groups of cells which, even if it is helpful, seems without any basis. Exception may also be taken to the suggestion that a narcotic "simply affects that part of the brain which is not affected by the disease" (insanity). There is no evidence for the localising views here implied. Dr. Shaw relates a case of trephining in acute insanity with the object of relieving pressure and thinks that "with a better knowledge of those localities specially affected in insanity of different kinds direct interference will be of service beyond our dreams." Before acquiring "better" knowledge we require simply knowledge of the localisation referred to, and we are not aware that there is any, nor have the years which have passed since these surgical procedures were advocated led to their adoption. Dr. Shaw is confident that many cases of chronic delusional insanity are left uncured because we have not the courage to attack them surgically. Certainly we cannot yet claim that surgical familiarity with the contents of the cranial cavity that exists with respect to the abdominal. The localisation of delusions, here referred to, is at present hardly within the realm of sober thought. In a case of olfactory hallucination where sclerosis of the olfactory centre was found, Dr. Shaw thinks operative treatment would have been proper. Do surgeons remove the tip of the uncinate gyrus? There is much sound sense in the author's remarks in his last chapter on the treatment of insanity and on the value of official figures as to recovery. We regret that space does not allow us to refer further to these and to other interesting matter.

LIBRARY TABLE.

The Purification of Sewage. By SIDNEY BARWISE, M.D. Lond., B.Sc. Birm., M.R.C.S. Eng., D.P.H. Cantab. Second edition. London: Crosby Lockwood and Son. 1904. Pp. 220. Price 10*s.* 6*d.*—We entertained a favourable opinion of this book in our review of the first edition in THE LANCET of March 11th, 1899, p. 700. Since then further progress has been made in the application of biological methods to the disposal of sewage. In particular, improvements have been made in the mechanical arrangements for making the action of percolating filters automatic and in apparatus for the distribution of sewage. This section of the subject receives attention in Chapter X. of Dr. Barwise's book. The text is interleaved with illustrations of these mechanical appliances. Further, Dr. Barwise has added an appendix on the analysis of sewage and sewage effluents which formed the subject matter of a book issued separately some years ago. Dr. Barwise's ample experience of modern methods of sewage treatment makes what he has to say of practical value and an excellent idea of the present position of the sewage disposal question will be gained from consulting this volume, while his directions as to gauging the efficiency of a given method of purification by chemical analysis are to the point. For the most part these methods are simple and give valuable indications.

Elements of Anatomy and Physiology especially adapted for Nurses. By W. BERNARD SECRETAN, M.B. Lond., F.R.C.S. Eng. London: The Scientific Press, Limited. 1905. Pp. 74. Price 2*s.* net.—When lecturing to the nurses of the Royal Berkshire Hospital the author was struck by the difficulty of obtaining a suitable text-book which although embracing the whole of anatomy and physiology as far as these subjects are required by the average hospital nurse was yet devoid of all unnecessary and confusing matter. This little manual is an attempt to provide such a work. It is concise, the language is simple, and it is sufficiently illustrated. The book will be useful to nurses.

Religion and Health: their Mutual Relationship and Influence. By NORMAN PORRITT, M.R.C.S. Eng., L.R.C.P. Lond., Consulting Surgeon to the Huddersfield Infirmary. London: Skeffington and Son. 1905. Pp. 186. Price 3*s.* 6*d.*—This is an interesting volume. After dwelling on the analogies between religion and health Mr. Porritt gives a survey of the effects of Christianity on the healing art, followed by a relation of the bodily ills that the absence of religion has carried in its wake. In his chapter on the cult of Mrs. Baker Eddy the author offers that lady many possible ways of proving the doctrine which she propagates. The book is intended specially for the ministers of religion and throughout it runs the expression of opinion that it is to the moral reformer—the minister, the priest, the clergyman, the lay reader, the evangelist—we must look to bring home to the people the grave injury to the race and the physical deterioration which are brought about by the neglect of the laws of health. Every minister ought to be a minister of health, for he penetrates where no one else can, he alone knocks at a man's door and claims the right to enter and yet not be considered an intruder. The minister and his helpers should be able "to render 'first aid' in health and sanitation." The gospel preached in this volume will benefit the work of any minister of religion who considers it; the tidings make for health and sanity. We have read the book with much pleasure.

Handbook of Diseases of the Ear, for the Use of Students and Practitioners. By RICHARD LAKE, F.R.C.S. Eng., Surgeon to the Royal Ear Hospital; Lecturer on Practical Otology at the Medical Graduates' College. With three coloured plates. Second edition. London: Baillière, Tindall, and Cox. 1904. Pp. x.-242. Price 6*s.* net.—We noticed the first edition of this useful work shortly after its appearance and we are glad to see that it has reached a second edition, for it deserves success. It is sufficiently brief and elementary to be suitable for the reading of those who are desirous of obtaining a good general knowledge of the subject without being overburdened by an excess of detail. The present issue does not differ to any very great extent from the first edition but a careful comparison of the two will show that numerous small alterations have been made, while here and there new sections have been added, for instance, the section dealing with rupture of the membrana tympani.

Burdett's Hospitals and Charities, 1905. London: The Scientific Press, Limited. Pp. 966. Price 5*s.* net.—The issue for the current year of this most useful work is quite up to the level of its predecessors. The information which it gives about hospitals, convalescent homes, homes for inebriates, and nursing institutions, not only throughout the British empire but in sundry foreign countries, is invaluable. The introductory chapters, too, whether we agree or not with Sir Henry Burdett's views, are most interesting reading. It is a book which no one who has anything to do with hospitals or their management can afford to be without.

The Land of the Blessed Virgin. By WILLIAM SOMERSET MAUGHAM. London: Heinemann. 1905. Pp. 228.—The land of the Blessed Virgin is Andalusia and Mr. Maugham possesses an evident faculty for enjoyment of that fascinating country. To begin with he can rightly appreciate the joys of laziness. Andalusia is a land where no one is in a hurry and for a worker in London, where most people have to do things whether they wish to or not, there is no greater charm than to go to a place where the prevailing feeling is, "If you can do a thing to-morrow don't do it to-day." Mr. Maugham seems to have found only one blemish—namely, the food; but in that respect we do not quite agree with him. He says: "The stomach used to roast meat and Yorkshire pudding rebels against Eastern cookery, and a Christian may sooner become a Buddhist than a beef-eater a guzzler of olla podrida." Rancid oil and garlic are not appetising here but they may be in Andalusia, and, like the Hebrews of old, anyone who has once been in the East, and Andalusia is the East, will remember the fish which he did eat in Egypt, the cucumbers and the melons and the leeks and the onions and the garlic. Mr. Maugham gives a delightful picture of Cordova and of Seville but Granada does not seem to have appealed to him so much as we should have expected. In one place he speaks of the sky being blue mixed with silver, an admirable description of the wonderful Spanish sky which produces the same effect on the eye as does a Morpho butterfly in certain lights. Altogether we commend this book as one written by a traveller who knows how to travel and who can rightly appreciate colour, sunshine, and the lotos land atmosphere of Moorish Spain.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, F.R.S. Vol. XXXII., No. 2. Feb. 28th, 1905. London: C. F. Clay. Price 7*s.*—The contents of this number are: 1. On the Distribution of Potassium in Animal and Vegetable Cells, by A. B. Macallum, professor of physiology in the University of Toronto, with two plates. Professor Macallum finds that the hexanitrite of cobalt and sodium in solution and in the presence of acetate of sodium precipitates potassium from its solutions, the precipitate being an orange-yellow triple salt which is, according to K. Gilbert's investigations, the hexanitrite of cobalt, sodium, and potassium. As revealed by this method potassium occurs in both the cytoplasm and the extracellular structures. The cell nucleus contains none, nor is there any in the head of the spermatozoon or in nerve cells. The quantity is scanty in smooth muscle fibre but in striated fibre there is a condensation of the potassium in the dim bands, the rest of the fibre being free from it. It is abundant in the granular zone of the secreting cells of the pancreas immediately adjacent to the lumen. 2. On the Relation of Enterokinase to Trypsin, by W. M. Bayliss and Ernest H. Starling. These authors support the view of the Russian physiologist Pawlow that enterokinase acts as a ferment upon a precursor or prozymin, trypsinogen, which it converts into trypsin. 3. The Physiological Effects of Peptone and Allied Products; Part vi.: The Metabolism of Arginin, by W. H. Thompson. Feeding with arginin occasions an increase of nitrogen in the urine the greater part of which appears as urea. 4. The Action of Anæsthetic Quantities of Chloroform upon the Blood-vessels of the Bowel and Kidney, with an account of an artificial circulation apparatus, by E. H. Embley and C. J. Martin. 5. Researches on the Autolytic Degradation of Tissues; Part ii.: On the Influence of the Thyroid on Autolysis, by S. B. Schryver. 6. Effect on Blood Pressure of Proteolytic Products, by C. G. L. Wolf. 7. Experiments on Cystin and its Relation to Sulphur Metabolism, by C. H. Rothera. 8. On the Inter-relationship of Calcium and Magnesium Excretion, by John Malcolme. 9. The Postnatal Changes in the Thymus of Guinea-pigs and the Effect of Castration on Thymus Structure, by Alexander Goodall. This number of the journal also contains the Proceedings of the Physiological Society for Dec. 17th, 1904, and Jan. 21st, 1905.

The Journal of Nervous and Mental Disease for January contains an article by Dr. S. D. Ludlum, assistant physician at the Friends' Asylum, Philadelphia, entitled "A Preliminary Report on the Possible Relationship of Neuro-Fibrillar Changes to Insanity." Dr. Ludlum's work is based upon the examination of nerve cells of the cortex, the medulla, and the spinal cord in two cases of insanity, in a starved rat, and in an artificially exhausted rat. For comparison he used fresh normal tissue of the rabbit and the rat. The neuro-fibrils were stained by Cajal's method. The changes were practically the same in the starved rat and in the insane patients, the neuro-fibrils being almost absent in the cell bodies, represented by broken pieces of fibril and by lines of fine granules, whilst they were less affected in the cell processes. The exhausted rat's cells showed an early change, taking the stain feebly and presenting swollen fibrils. One of the patients was a case of mania-melancholia of long standing with mild dementia, in which acute depression came on 16 days before death. Dr. Ludlum thinks that the state of the neuro-fibrils accounts for this depression and that this state plays an important part in the insanities arising from malnutrition. He deduces this from the experiments upon the rats but all these experiments show is that under the conditions produced (starvation and exhaustion) the neuro-fibrils degenerate. The changes observed in these fibrils in the first insane patient might have been the result of the long-standing brain disease, not the cause of the final exacerbation of insanity which preceded death. The same explanation, that the changes were merely the outcome of disease, may be applied to the second case examined, which was that of a general paralytic. It is obvious that the task of separating cause from effect is rendered more difficult by working with cases of long-standing disease. This number also contains a report of a meeting of the New York Neurological Society held in October, 1904, at which Dr. B. Sachs opened a discussion on Dementia Præcox. Dr. Sachs thought that widely different cases were grouped under this term with little gain, that the old plan of clinical subdivision was more commendable, and that too grave a prognosis was given in the youthful insanities. The tenor of the discussion was to show that different types of mental disease were embodied under this heading and that in course of time subdivisions would be formed out of the cases so grouped, the present grouping being only provisional.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The Registrar of the Royal College of Physicians of London [illegible] for the Membership [illegible] instead of [illegible] week.

THE LANCET.

LONDON: SATURDAY, MARCH 11, 1905.

The Registrar-General's Sixty-Sixth Annual Report.

WE are indebted to the Registrar-General for a copy of his annual report for 1903, a volume which is always welcomed by THE LANCET and which this year has seen the light several months earlier than is usual. In reviewing previous issues of this work we have given expression to the hope that having regard to their importance to a large section of our profession these reports might in future be issued within a reasonable time after the close of the period to which they relate. It has not escaped our notice that in the final remarks appended to his first annual report the present Registrar-General endeavoured to justify the late appearance of these reports on the ground that more expeditious preparation would probably lead to less accurate, and therefore unsatisfactory, results. We are, of course, aware that the Treasury authorities are constantly clamouring for reduction of expenditure in the conduct of the Government offices under their control and we believe that the General Register Office is one of these. But we trust that Sir WILLIAM DUNBAR will forgive us if, on the ground of the high appreciation in which his reports are held by the medical profession, we urge yet again that increased efforts should be made to render them available more promptly—at any rate, in a shorter period than the 14 months which now have elapsed since the completion of the year dealt with in the report before us.

The Registrar-General's sixty-sixth annual report suffers nothing by comparison with its two predecessors, both of which we noticed in appreciative terms at the time of their publication. Several new features will be found in the present report. The presidents of the statistical bureaux of the principal European countries have responded to the invitation to augment the somewhat meagre information hitherto published in these reports with respect to the births, deaths, and marriages in the several countries and the Registrars-General of those British colonies in which records are available have for the first time contributed such information as they possess. The results now appear in the form of a new series of tables giving fairly uniform particulars for some 28 foreign countries, not only of births, deaths, and marriages, but of infantile mortality and of the mortality from the chief epidemic diseases, as well as from cancer and pulmonary tuberculosis. Not all of the foreign countries addressed have been able to comply fully with the English request but the Registrar-General entertains the hope that in process of time the list of countries able to furnish trustworthy statistics will be extended, thereby increasing the value of these international records. In view of the widespread anxiety caused both at home and abroad by the continued depression of the birth-rate the ordinary methods of presenting the ratios of birth and of marriage have been subjected to criticism in the General Register Office. As a result we learn that the total population is not the most satisfactory basis for the calculation of rates. As regards marriage-rates, a better standard is obtained by eliminating the already married persons from the population and by calculating the rates on the unmarried and widowed who are living at ages beyond 15 years, thus dealing with that section of the people among whom alone marriages take place. Calculated by this method the English marriage-rate is seen to have declined steadily throughout the last 20 years, whilst the rate computed in the ordinary way indicates, on the contrary, a slight increase in that period.

With regard to the birth-rate again we learn that the total population is not the best standard by which it may be measured because it does not take account of the age constitution of the female population and particularly of that portion of it which is of child-bearing age. For example, the population of women aged 15–45 years to the total population, which was 23·1 per cent. in 1871 and in 1881, rose to 25·0 per cent. in 1901; if, therefore, the average fecundity of the female population had remained constant the births registered in 1903, which, as a matter of fact, numbered only 948,271, would have amounted to more than 1,250,000. In view of these facts it is evident that a preferable method by which to measure the birth-rate is to calculate the proportion of births per 1000 women of child-bearing age. The disturbing factor of changing constitution of the population is mainly, though not entirely, eliminated by this method of measuring the birth-rate, which shows the amount of decrease to be far greater than that indicated by the rates based on the aggregate population. We have not space to reproduce the interesting tables in the report which fully support the above contentions, but we may say generally that whereas the English birth-rate calculated in the ordinary way appears to have decreased by 6·8 per cent. only in the last ten years the decrease computed on the numbers of women aged from 15 to 45 years is shown to have amounted to 11·5 per cent. As regards the calculation of rates of mortality, the same disturbing factor of changing age constitution of the living is operative in a similar way and necessitates the adoption of a standard population which is assumed to remain constant in regard to age and sex. In England this has for some years been the practice but owing to the impossibility of satisfactorily estimating the numbers of these sections of the population and of ascertaining the sex and age constitution of the people in the various foreign countries for which the details are now published, it is only possible for the purposes of international vital statistics to employ the total population as the basis for calculating the rates of birth, marriage, and death. In close relation to the question of a declining birth-rate, especially in those countries where the decline is serious, is the question of mortality among the infants who survive. With few exceptions we learn that a high rate of infantile mortality prevails in those countries possessing a high birth-rate; nevertheless, English experience shows that a high rate of infantile mortality may accompany a comparatively low birth-rate. In this country in the ten years 1893-1902 infantile mortality averaged 152 per 1000 births. Of 24 countries or colonies furnishing the necessary data there were seven—viz., Italy, Chili, Ceylon, Prussia, Jamaica, Hungary, and Russia—where the average birth-rates ranged from 34·3 to 48·6 per 1000 of the population and the average infantile mortality ranged from 170 to no less than 333 per 1000 births. On the other hand, in Scotland and in Norway, with comparatively high birth-rates of about 30 per 1000, the average rates of infantile mortality were as low as 127 and 94 respectively in each 1000 births. Of the 28 countries furnishing returns France has the lowest average birth-rate, while the average rate of infantile mortality in that country amounted to 158 per 1000 births. In 13 of the 16 countries contributing additional statistics for the year 1903 infantile mortality was below the average of the previous ten years—the exceptions being Chili, Jamaica, and Queensland.

The question of the falling birth-rate in this country as well as in other parts of the British Empire has been prominently brought to the notice of the public by the recent Royal Commission on the Decline of the Birth-rate in New South Wales and by the interesting and instructive report of the Duke of DEVONSHIRE'S Inter-departmental Committee on Physical Deterioration. In connexion with this subject it is necessary to repeat a statement which has been many times advanced in these columns—namely, that the rate of mortality is affected in a serious and peculiar manner by changes in the birth-rate. The first effect of a continuous decline in the rate of birth is to *lower* the rate of mortality owing to the reduced proportion in the population of very young children, among whom the death-rate is always very high. In subsequent years the death-rate, as measured by total population, will be increased owing to the smaller numbers of survivors reaching those ages which are subject to lower death-rates; and this effect will last so long as the survivors of those born before the birth rate began to decline form an abnormally large proportion of the population.

With regard to the proportion of deaths among the population that remain uncertified either by medical men or by coroners the Registrar-General remarks that the percentage of uncertified to total deaths in the year 1903 was the lowest on record. With reference to this subject, however, particular attention is directed in the report to the still abnormally high percentage recorded in the counties of Carnarvon and Hereford, as well as in the boroughs of Gateshead, Warrington, South Shields, and St. Helens, all of which held the same unenviable position in the annual report for 1902. It is, however, a remarkable coincidence that each of the above localities should have a *high* proportion of uncertified deaths together with a correspondingly *low* proportion of inquests. Analysis of the returns shows that the percentage of inquests and uncertified deaths to the total deaths in England and Wales was respectively 6·9 and 1·7. In the above-mentioned counties and boroughs, however, the proportion of inquests was low, ranging only from 3·6 to 5·5 per cent., whereas the percentage of uncertified deaths was excessive, ranging from 4·0 to 6·7. The Registrar-General, therefore, expresses the hope, in which we fully concur, that the coroners of these districts will give their cordial support to the object aimed at, by considering whether it might not be attained by holding inquests more frequently in the case of uncertified deaths which are referred to them. In the present connexion, however, and in justice to the coroners we may mention an important fact which probably may be unknown to the Registrar-General—namely, that the decision as to the number of inquests to be held in any particular place does not always rest with the coroner who in recent years has become in certain cases the officer of the local authority. As the holding of inquests means a considerable increment to the local expenditure it will readily be understood that these authorities will in some cases endeavour to reduce that expenditure to the lowest practicable amount. Having devoted so much space to a consideration of the important innovations in the Registrar-General's present report we have no room left for noticing the question of the death-rate, which is, after all, of most importance to our readers. To this subject, however, we purpose to return hereafter; meanwhile we congratulate Sir WILLIAM DUNBAR on the fact that the death-rate of England and Wales in the year 1903 was the lowest since the establishment of civil registration.

School Legislation and the Demands of Hygiene.

OF all the social problems which demand solution at the present day none is more urgent than that implied in the hygienic management of the children whom legislative enactments compel to attend our elementary schools. Since attendance is enforced rigorously by law, it is an obvious duty of the State to insure that school life shall not be fraught with danger to the health and the happiness of the scholars. There are reasons for thinking that a satisfactory state of things is as yet far from realisation. Only too often do we hear complaints from parents that school life involves risks of infection, with maladies of varying degrees of seriousness, which no amount of care can avoid. Many medical authorities, upon good evidence, are inclined to associate the great increase that has taken place in the prevalence of diphtheria with the herding together of children for purposes of instruction. If it is difficult to acquit our school system of all responsibility for the propagation of epidemic diseases, yet so far no trustworthy statistical evidence has been available for estimating the extent of its evil influence. A very interesting attempt to remedy this defect of evidence has recently been made by Dr. MYER COPLANS, the medical inspector of the schools which are under the Gloucestershire Education Committee, whose report to a subcommittee of this board will, we believe, shortly be published. Dr. COPLANS examined medically 6652 children in the schools of the Stroud district with a view to ascertain the effects of school life in spreading infectious diseases or evoking other ailments and the results of his inquiry tend to acquit the school system of so great a share in the propagation of scarlet fever, measles, and diphtheria as is sometimes assigned to it. We hope that this conclusion will be justified on further inquiry, but the question is very difficult to decide. The comparative prevalence of infectious maladies among children too young for attendance at school and among those of school ages affor[illegible]or example, no sound test, for we have to bear [illegible] and t[illegible]ren not yet old enough to go to school associate at home with those who do attend and that if a single child of a family contracts, say, scarlet fever at school he will probably be a source of infection to his younger brothers and sisters. Hence the fact of children suffering from such maladies before they reach school age does not acquit the school of responsibility for spreading the disease. The original source of infection in the case of many infants may have arisen thus. The comparative susceptibility of children at different ages also complicates the question, for if infants are more liable to suffer than older children, then the number of sufferers at home will tend to rise disproportionately when infection is introduced into any district. Only a comparison of the figures for each class extending over a long period of time could supply trustworthy grounds for arriving at a conclusion.

The Dundee Social Union lately has directed the preparation of a series of reports upon the physical condition of a large number of children attending six Dundee schools—four under the control of the Dundee school board and two voluntary schools. The reports have been made upon 1000 children taken upon no selective plan from the registers of the schools and have been collated by Miss MARY L. WALKER and Miss MONA WILSON, with the valuable assistance of Dr. CHARLES TEMPLEMAN, medical officer of health of Dundee, who has furnished an introduction. The report on the general medical examination of the boys was made by Dr. ALEXANDER P. LOW and of the girls by Dr. EMILY C. THOMSON, while Dr. G. TAYLOR GUILD reported on the ears, throats, and noses of the children, and Dr. E. F. MACLEOD NEAVE and Dr. W. E. FOGGIE on their eyes. The results are exceedingly interesting and show, as Miss WALKER and Miss WILSON say in their general preface, that an enormous amount of actual suffering among children is unnecessary or preventable, though the causes of the various evils being many the remedies must also be many. Taking pediculosis as an example of an obviously and easily preventable malady we find that of 1000 Dundee children the number, not only of those who were verminous but of extremely bad cases where the heads and the bodies of the children were in a foul state, was large. As a numerical statement under the heading of "cleanliness of body" 177 of the 1000 were classified as "bad," a tabulation which indicates the presence of vermin. Let us pass now to the more important subjects of physical development and definite bodily lesions. Some average measurements of Dundee children were submitted to the Inter-Departmental Committee on Physical Deterioration as evidence of retarded development and these figures have since been confirmed by the larger number of observations made at the instance of the Dundee Social Union. In these last-mentioned observations the average weights and heights of children from five to 13 years of age attending the elementary schools are compared with the weights and heights furnished by Mr. FRANCIS GALTON to the Anthropometric Committee of the British Association in 1881 and with figures given by that committee in 1883. At a secondary school in Dundee—the Harris Academy—480 children were also weighed and measured in order that a comparison might be made between children attending the elementary schools and children living in the same locality under better home conditions. At all ages from five to 13 years the height of the boys attending the Dundee elementary schools compares unfavourably with Mr. GALTON'S figures, while the average weight of boys of 13 years is about nine pounds less than Mr. GALTON'S estimate and the average weight of girls of 12 years attending the elementary schools is more than nine pounds below the average of the girls attending the Harris Academy. The children in the Dundee elementary schools were, at all ages from which a comparison could be made, distinctly below those at the Harris Academy in both weight and height.

Of the diseases of special organs and regions described in the reports compiled for, and published by, the Dundee Social Union we can only mention those affecting the heart, the eyes, and the teeth. Heart diseases were found in the large proportion of 7·47 per cent. of the children; among the boys these included 30 instances of valvular defect, the several forms being mitral stenosis, mitral incompetence, pulmonary systolic murmur, and slight impurity of the first sound in the mitral area. With respect to vision it was found that only 52·2 per cent. of the children could see to read the standard types at the proper distance. This did not necessarily mean that their refraction was normal, for, as a matter of fact, only 26 per cent. showed normal refraction and the remainder must have been straining their accommodation in order to read the types. The examination of the teeth led to the general result that caries of the teeth was very prevalent, hardly any of the children being free from it. Attention has been drawn lately to the insufficient food upon which many of the children of the poor have to subsist and to the impossibility of ill-nourished brains assimilating a due amount of mental pabulum. The food may in other instances be sufficient and the child yet may be unable to thrive upon it owing to defect in those much-neglected organs the teeth. An inquiry carried out by Mr. E. RICE MORGAN[1] into the state of the teeth of children in the Swansea educational area showed that of 295 children of both sexes only 11 had mouths free from dental defects, while on an average each child had more than three decayed teeth. Such figures need no comment. If we cannot, as HORACE says, permanently expel nature with a pitchfork, we may yet perhaps repel physical degeneration with a tooth-brush. The result of reading these various interesting reports is to learn how much preventable disease is present among the children of the poor; while the depression produced by this knowledge is tempered by the feeling that never before have so many wise and charitable efforts been directed towards the problems of school hygiene as are now at work.

The Colonies and Cancer Research.

A GOVERNMENT Blue-book of some 96 pages dealing with the subject of cancer research has just been published and presented to both Houses of Parliament. It contains the correspondence between the Colonial Office and the governors or high commissioners of the various colonies with the object of acquiring information as to the incidence of malignant disease and its causes, together with material both from man and animals for the Cancer Research

---

[1] Swansea Education Committee. Quarterly Report upon the Schools in the Upper Division of the County Borough of Swansea, by E. Rice Morgan, medical officer. Dec. 28th, 1904.

Committee to investigate. While its publication is a welcome evidence of the general interest which is now aroused by the inquiry into the nature and the causes of malignant disease, it must be confessed that as regards the information which it contains it is, on the whole, very disappointing. A gratifying feature of the book is the active and sympathetic interest in the work evinced by so many of the high officials of the colonial service. Both Mr. JOSEPH CHAMBERLAIN and his successor as Colonial Secretary, Mr. ALFRED LYTTELTON, emphasise very strongly and repeatedly the importance of the research, while many of the governors write sympathetically of the objects of the Cancer Committee and promise to assist by all means in their power the furtherance of those objects. Among these we may mention especially Lord MILNER and Sir F. M. HODGSON, the former of whom made valuable practical suggestions, which were subsequently adopted by the Imperial Cancer Research Fund, to promote the acquisition of material for microscopical investigation. The correspondence begins with a circular letter by Mr. JOSEPH CHAMBERLAIN, then Colonial Secretary, dated May 27th, 1903, and addressed to the governors and high commissioners of all colonies and protectorates, containing inclosures giving details of the scheme for cancer research and describing the constitution of the executive committee being formed for that purpose, together with an outline of its aims and requirements, with a view of "enlisting general interest in the scientific objects as well as the pecuniary position of the fund." Mr. CHAMBERLAIN in his letter requests that the matter may be furthered by giving publicity to it and by any other suitable means. This was followed by a second circular letter, dated May 29th, 1903, addressed to governors and high commissioners of Crown colonies and protectorates, inclosing a memorandum drawn up by Dr. E. F. BASHFORD, the general superintendent of research, and stating that "great importance is attached by the directors of the inquiry to the scientific investigation of cancer in communities where the conditions of life differ so widely as in the British Crown colonies," and requesting that the medical officers will carry out the directions in Dr. BASHFORD'S memorandum as completely as possible. A similar despatch was sent out next day to the governors of responsible government colonies Copies of these documents were sent to the Foreign Office with the request that, subject to Lord LANSDOWNE'S approval, they might be sent to protectorates administered by the Foreign Office. On Jan. 13th, 1904, Mr. LYTTELTON sent out another circular letter giving details of the results obtained up to that time and requesting information from those colonies from which no reply had then been received and urging "the necessity of not allowing this important matter to drop but of doing all that is possible to obtain for the Commission the material and information which they require for their difficult inquiry."

The replies to these repeated requests for information with a few noteworthy exceptions, among which we may specially mention those from Ceylon, Mauritius, Barbados, the Transvaal, and Queensland, have been unsatisfactory, varying from an almost curt statement of the impracticability of acquiring the information desired to a mere general statement or even a vague expression of opinion without statistics to support it. It cannot be too strongly urged that such expressions of opinion, though interesting and perhaps in some instances containing important truths, are valueless from the point of view of exact scientific investigation. From a number of colonies where there are extensive native or aboriginal populations, such as British Central Africa, British East Africa, and the Gold Coast, the medical officers state with almost striking unanimity that cancer is rare or unknown amongst them, and yet isolated cases are from time to time recorded, so that the possibility of conditions operating to prevent such cases coming to the notice of the medical officers, as pointed out by the committee of the Cancer Fund, must not be lost sight of. At the same time it is just in such countries that statistical details would be of the utmost value could they be obtained, for although the value of statistics is a matter of much dispute and often ridicule, at the present stage of cancer investigation, when we are groping in the dark for likely clues, statistics may afford valuable and promising indications of lines of research, more especially if it should be found that the incidence and the most frequent site of the disease are found to vary in different countries. Thus if it should be substantiated that cancer is rare amongst certain aboriginal tribes in certain countries a promising field for research would be opened up.

Among the most interesting reports sent in response to the circular letters from the Colonial Office is that from Sir ALLAN PERRY, principal civil medical officer of Ceylon, summarising the cases of cancer and sarcoma observed there. He finds that about 220 deaths occur from these diseases per annum; that cancer is a comparatively slight disease in Ceylon, one death from cancer occurring in every 16,820 persons living in 1903. In striking contrast to the condition in this country he finds that it is more common in men and that the most common site is in the oral cavity, which accounts for 55 per cent. of the cases. The preponderance in this situation is not confined to men but is also nearly as marked in women. The next most common situation is the penis which is affected in 32 per cent. of the cases. Cancer is stated to be more common in the northern province of Ceylon and it is suggested that the frequency of the mouth as the primary site is due to chewing betel which consists of tobacco, betel leaves, areca nut, and a little slaked lime It is said that the people of the northern province are much addicted to betel chewing. The report of Dr. H. LORANS, acting medical director of Mauritius, is also of interest. He concludes from the statistics of cases treated in the general hospitals that cancer in Mauritius is much less prevalent than in England. During 1903 67 cases of malignant growth occurred among a total number of 21,356 patients treated and 20 only out of 1277 deaths in the hospitals were due to malignant disease. Statistics such as those from Ceylon and the equally interesting statistics of the Mayo Hospital, Lahore, published by Captain D. W. SUTHERLAND, I.M.S., in the Third Report of the Cancer Research Laboratories of the Middlesex Hospital, show that valuable information may be obtained from the statistical investigation of hospital and other records. No doubt the difficulties in the case of some of the colonies are very great, especially where there are large native populations and no system of death registration, but much could be done in the matter of careful record of individual cases and the determination of the proportion which they bear to the total number of cases seen by each medical officer of those countries. We feel sure that the circular letter of Mr. LYTTELTON, dated Nov. 18th, 1904, pointing out the great importance of this very question of the incidence of cancer among native populations will meet with a generous response from the medical practitioners of those districts.

Annotations.

"Ne quid nimis."

CONVALESCENT HOMES ASSOCIATION.

A CONFERENCE of delegates from all the chief convalescent institutions supplying charitable relief to London patients was held at 20, Hanover-square, London, W., on March 2nd, Sir E. Hay Currie being in the chair. The Presidents of the Royal Colleges of Physicians of London and Surgeons of England and the President of the Hospitals Association were present, together with representatives from the following convalescent homes: Metropolitan, Seaford, Eastbourne, Gladstone, and St. Andrew's, Folkestone. The object of the conference was to obtain some form of union and coöperation between the various convalescent homes and it was thought that that could be best initiated and carried out through a central association in immediate touch with the hospitals on the one hand and the homes on the other. The first of the four propositions submitted, which were all unanimously agreed to, was that the increasing needs of medicine and surgery required some alteration in the character of the relief afforded by convalescent homes to the poor of London. In proposing this motion, Sir William S. Church said that the conference was not intended to reflect in any way on convalescent homes. All members of the medical profession were most grateful for the benevolence which had provided such institutions. He explained how the one scale of diet that was the rule at convalescent homes rendered them unsuitable places for the after-care of patients recovering from certain well-known diseases. He also pointed out the disadvantage of another almost universal rule that no patient could be received at these institutions who had an open wound. These defects could be obviated by rearrangement amongst the homes. Mr. J. Tweedy, who seconded the motion, showed how the need had arisen for alteration in the character of the relief afforded to convalescents. Sir Thomas Smith pointed out how the great increase in the number of operations at the London hospitals had intensified the need for the conference which had been convened. Sir R. Douglas Powell insisted on the recognition of the fact that there was no necessity for building new institutions and explained how the present accommodation for convalescents could be utilised by means of suitable coöperation. The next motion, proposed by Mr. E. A. Gruning, seconded by Lady Frederick Cavendish, and supported by Mr. M. O. Fitzgerald, arranged for the formation of an association to be called "The Convalescent Homes Association," which shall consist of convalescent institutions supplying charitable relief to London patients, the object of the association being to form a representative council to centralise effort and to promote efficiency and economy. On the proposition of Lord Lytton, seconded by Dr. J. Kingston Fowler, it was decided that the council shall consist of one representative from each convalescent institution and one representative from each of the great general hospitals of London and of such other lay and medical representatives whom it may be considered advisable to invite, the following to be *ex-officio* members of the council: The Presidents of the Royal Colleges of Physicians of London and Surgeons of England, the Dean of the Faculty of Medicine of the University of London, the President of the Central Hospital Council, and one representative from each of the great hospital funds. Sir Henry Burdett in a short speech proposed that a small executive council should be elected from the general council and that the honorary secretaries should be Dr. S. H. Habershon and Mr. Fitzgerald. This was seconded and after having been duly passed by the meeting a hearty vote of thanks to the chairman concluded the proceedings.

"THE NATION'S DRINK."

UNDER the above heading the *Standard* has recently published two admirable articles by "an expert" on (1) wine made in England; and (2) whisky made in England. The readers of THE LANCET well know our attitude upon the subject of drink and its adulteration and the writer in the *Standard* indorses in a striking way all that we have written. He completely exposes the humbugging tricks of a certain, and, it is to be feared, very large, section of the wine and spirit trade and his contribution throughout furnishes a strong appeal for immediate and serious legislative intervention. The worst feature of it all is, perhaps, that the practice of blending spirits is conducted under the very noses of Government officials who know perfectly well how flagrantly misleading to the public is the nomenclature adopted on the labels of bottles of brandy, whisky, and other spirits. We are almost weary of keeping these facts before the notice of our readers but our hope is that by doing so the day of retribution will be brought near. When shall we have a Government brave enough honestly and seriously to face this question? The articles in the *Standard* are surely sufficiently convincing for any intelligent person and they are evidently written by a well-informed writer. If they are not convincing the statements are a sufficient indictment to warrant the appointment of a committee of inquiry to determine what are the real facts. Its labours would, we are sure, reveal a discreditable state of things. If the public were merely conceded an honest description and an honest label they need hardly ask for more. The detention of all spirits in bond for a specified number of years would, we fancy, be a wholesome provision for the nation and the adoption of a revenue stamp on the bottle certifying how long the spirit had been so detained would be a progressive step.

THE IMPORTATION OF DISEASED PORK FROM DENMARK.

AN interesting correspondence has recently taken place between the Danish Minister of Agriculture and the medical officer of health of the City of London in regard to the importation of diseased meat from Denmark. It would appear that some years ago an arrangement was made that in all cases in which such meat was condemned in the City markets as unfit for food the labels attached thereto should be forwarded to the Danish Commissioner in order that inquiries might be made in each particular case. This system of returning labels was agreed to, provided that steps should be taken which would preclude the possibility of any diseased meat being imported from Denmark. So far as relates to beef this system produced an excellent result but it has miscarried in the case of pigs. During the three months October, November, and December, 1904, Dr. W. Collingridge reports that 39 pigs so marked were seized and during the first fortnight of the present year 49 more were condemned. This would appear to be due to the application by the City medical officer in 1903 of the recommendations of the Royal Commission on Tuberculosis—recommendations, however, which were not generally adopted in Denmark. Subsequently (in January, 1905) "a Supplement to Instruction" was issued to the veterinary inspectors in Denmark in the following terms: "As it has been brought to the notice of the Minister that carcasses of pigs which have suffered from tuberculosis, even in a very minute degree, are condemned by English officers of health as unfit for human food, it shall from now henceforth be the duty of the veterinary inspectors authorised to inspect meat for export to retain from export to Great Britain the carcass of any pig examined according to the order of August 15th, 1903, in which, or in the organs of which, is found the smallest deposit of a tuberculous nature." Further, "as the removal of any part of the serous membranes in several markets in England causes a suspicion that the animal in question has suffered from tuberculosis, the veterinary inspector shall not pass for export to Great Britain any carcass of an ox or pig examined according to the said order from which any part of pleura or peritoneum has been removed." It is pointed out that carcasses of pigs showing no sign of disease when slaughtered will, nevertheless, if sent off closely packed before being properly cooled, arrive in a distant market in a state unfit for food. Small pigs in particular have of late developed a rickety state and it being unprofitable to "feed them off for bacon" they have been killed young for pork in many cases for export. Whilst these have been found perfectly sound and fit for food at the slaughter-house such has not been the case for export. Such carcasses have therefore not been detained by the inspector. In future, however, according to an additional "instruction" issued on Jan. 18th, "carcasses of pigs must not be passed for export before they are quite cold and in that state have been found perfectly firm and dry. Carcasses of rickety pigs must not be passed for export." Dr. Collingridge is to be congratulated on the satisfactory results of his representations and a word of praise is due to the Danish Government authorities for the courteous manner in which they have received these representations and have acted upon them.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

THE sixth lecture of the series[1] was delivered by Professor W. F. R. Weldon at University College, London, on Jan. 31st, the subject of discussion being the Mendelian theory of heredity. This theory published in 1865 was forgotten for long and was rediscovered and brought into publicity in 1902. Mendel's work consisted of a laborious and long-continued investigation, chiefly carried out on certain varieties or races of peas and constituted an advance in the knowledge of the formation of hybrids, of the theory of inheritance, and of other biological matters. It was the first attempt to elucidate from the systematic study of heredity in definite races and varieties a formula of inheritance of characters. He thus crossed peas which had special differential characters as regards colour of cotyledons (yellow or green), shape, and outline (round, smooth, or considerably wrinkled). He found *on crossing* green-seeded plants with the yellow-seeded variety that the hybrid progeny of the first generation was uniformly yellow. This was an instance of dominance of the yellow character, the green character having become latent in the products of the crossing. These yellow hybrids, however, when intercrossed, gave rise to a mixed progeny of yellow-seeded and green-seeded plants, in the proportion of three yellow to one green, the latent green character reappearing in one-fourth of the descendants while the yellow still continued to show its dominance in the remaining three-fourths. The green character was thus seen to be recessive, and the yellow dominant, in the hybrids. These recessive green hybrids, when carefully intercrossed bred true—the offspring were always green (purity of character). The dominant yellow hybrids, however, were only apparently pure, for when intercrossed they produced varied or mixed offspring—viz., true yellow plants which reproduced yellow descendants and spurious yellow plants which yielded both yellow and green descendants. To account for these facts Mendel designed a scheme or formula of inheritance in which the colour, form, and outline (smooth or wrinkled character) of the seeds were made to depend on embryonic "determinants" supposed to be present in the pollen grains and the ovules of plants. (The subject of determinants was discussed and explained in the fifth lecture.) Cast into the form of a genealogical table of generations the following represented the actual facts:—

1st generation.	Green seeded "pure" plant.			Yellow seeded "pure" plant.
2nd generation.	Yellow hybrids all. By intercrossing they yielded the following —			
3rd generation.	Yellow (pure type).	Yellow (impure *type*).	Yellow (impure *type*).	Green (pure type).
4th generation.	Yellow (pure type).	Mixed green and yellow offspring.	Mixed green and yellow offspring	Green (pure type).

Mendel states that the determinants of certain characters showed in some cases repulsion towards determinants of other characters, that on the whole they tended therefore to segregate, and that in one generation certain determinants grew potent while others became latent. The distribution of the determinants, he said, was governed broadly by the law of chances or probability, and the distribution of the coloured seeds accordingly followed the same law. Thus it was possible to account for several of the actual facts and numerical proportions of characters obtained by the interbreeding of various races. Quite similar results in transmission occurred when long smooth peas were crossed with deeply wrinkled peas. In this case roundness was dominant in the first generation of hybrids. These hybrids when intercrossed gave rise to mixed offspring in the proportion of one of the wrinkled type to three of the smooth and long-seeded type. Finally, of the three smooth and long-seeded type two produced in turn mixed seeds and one produced round seeds. These conditions of colour, shape, wrinkling, and smoothness were *severally independent in transmission* and therefore complex segregations of characters occurred in later generations of the hybrids. Thus experimenting with two types of peas—viz., a green wrinkled form and a yellow round form—some 16 varieties of hybrids showing distinct aggregates of characters were obtained in a series of experiments conducted over four generations. To elucidate the complex process of the hereditary transmission of characters Mendel postulated a theory of "gametic purity" which has found many adherents at the present day.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE annual report of the council of the London and Counties Medical Protection Society was presented at the annual general meeting of the members held at the offices of the society at 31, Craven-street, Strand, London, on March 3rd, Dr. J. W. J. Oswald being in the chair. The first part of the report is taken up with the discussion of the new schemes of medical defence and the council states that it is still waiting for some definite proposal to be made by the British Medical Association before binding itself to any definite course of action. Under the heading of "A Stitch in Time" the council impresses upon its members the importance of referring matters to the society at the earliest possible moment. Every year loss falls upon the society and upon one or two of its members owing to delay in reporting threatened troubles to the society. Occasionally also members begin by attempts to deal with difficult matters for themselves and only refer to the society when it has become obvious that a wrong line of action has been adopted. This is contrary to their own interests and the council advises that when a member becomes aware that accusations of negligent treatment are likely to be made or have already been made against him he should apply at once to the society and not, as often happens, begin by giving unrestrained vent to his wrath and then proceed to hand over to the society a case already prejudiced. In one case a member had his account for medical attendance disputed on the ground of alleged damage by a plaster which the patient said was a pitch plaster whereas it should have been a belladonna one. The member sued for his fees in the county court and the society's general secretary gave evidence on his behalf. The evidence showed that no mistake had been made and that the treatment was proper. The county court judge ruled that the medical man was in any case not liable and the patient was ordered to pay the medical man's bill. The claims during 1904 against members for damages for alleged negligence or unskilful treatment were uncompromisingly resisted and after more or less prolonged proceedings were abandoned. The forms of negligence and unskilfulness alleged were of very varied character and exemplified some of the disadvantages arising from a fancied knowledge of medicine by patients and their friends. In one case where a servant girl had been the source of a story to the effect that a member of the society had committed an indecent assault upon her under chloroform the prompt investigation instituted by the society put an end to what proved to be an absolutely impossible story. The society has also been able to check a considerable amount of the malicious gossip which is often very detrimental to medical practitioners. In view of the steady increase in the amount of the reserve fund, which on Dec. 31st, 1904, represented £2402, the council has decided to impose an entrance fee of 10*s.* on new members joining the society. Owing to the fact that the society has closed the year with two heavy cases for hearing in the High Court on hand the legal expenditure for the 12 months has exceeded that previously incurred in any one year by the society. The annual report and the balance-sheet were unanimously received and adopted by the meeting and the President, Vice-Presidents, council, officers, and auditors were all re-elected.

---

[1] Abstracts of the first, second, third, fourth, and fifth lectures were published in THE LANCET of Jan. 7th (p. 42) and 21st (p. 181), Feb. 4th (p. 307) and 25th (p. 512), and March 4th (p. 634), 1905, respectively.

UNITY OF THE TUBERCLE BACILLUS.

EVEN those who hold most tenaciously to Koch's contention in favour of the duality of human and bovine tuberculosis must admit that the evidence which he adduced was almost wholly of a negative character and the results of subsequent researches have been such as to leave no reasonable doubt as to the essential identity beneath superficial and accidental differences of the bacilli of tuberculosis, avian as well as mammalian. This has recently been demonstrated by the almost exhaustive investigations reported in a "Habilitation Schrift" by Dr. Paul H. Römer of Marburg, embracing every possible combination and permutation of factors save only inoculation of the human subject. He experimented with no fewer than 52 strains derived from man, cattle, and rodents, and two from birds; these he passed in varying sequence through cows, sheep, goats, horses, guinea-pigs, rabbits, white mice, and fowls, cultivating them in glycerine serum, glycerine agar, potato agar, potato glycerine, and glycerine broth, diluting with physiological salt solution in regulated dosage for purposes of inoculation. The general results of his experiments, which with tables and plates fill over 100 pages, were that all animals were susceptible to infection by each and every strain, though some methods of culture and the passage through particular species of animals enhanced, and others enfeebled, the virulence of certain strains, and that consequently smaller or larger doses might be required. Thus, white mice, said by many observers to be immune, succumbed to long treatment with large doses of No. 1, a tubercle bacillus of human origin that had been cultivated for seven years and passed through a long succession of guinea-pigs. The differences in the appearance of the several cultures were determined by the media and the methods of cultivation rather than by the original source, some forming moist, viscid, and slimy deposits and others a dry, wrinkled felt, while morphologically some human, bovine, and ovine strains were quite indistinguishable and animals infected with one—e.g., ovine—tubercle culture reacted to human, bovine, and other tuberculins as well as to ovine, and *vice versâ* each tuberculin caused a reaction whatever the source of the tuberculous disease. Generally a strain more virulent than another to one animal was found to be so to all others under all conditions. The order of susceptibility was the guinea-pig, the rabbit, the horse, the goat, the sheep, and the ox, guinea-pigs being the most, and oxen, contrary to general belief, being the least, susceptible. The avian tubercle was obtained from two fowls which had fed on, and probably had been infected from, the viscera of a cow which had died from tuberculosis. Unlike the mammalian tubercles it was most virulent to cattle and least so to guinea pigs, unless previously passed through some other mammal. Its immediate action on the guinea-pig was shown rather in the setting up of a toxic pneumonia than of the usual tuberculous process, but the most remarkable feature of this strain was that whether introduced by intravenous or intramuscular injection it failed to infect other fowls, although it was very virulent to rabbits. Intentional experiments on man are, of course, inadmissible, though from time to time we hear of undesigned and accidental inoculations with bovine tubercle, an instance of which was recently reported by E. Schindler of Prague.[1]

THE NEW CONVICT PRISON RULES.

IT has been a much debated question whether any attempt should be made to reform those who are sentenced to long terms of penal servitude. Elaborate experiments in this direction have been tried in America at the Elmira State Reformatory in New York and at the convict prison at Neudort, near Vienna, but with regard to Elmira it seems that the Government of New York State has declined to support the institution on the ground that the prisoners were made too comfortable. While it may be impossible to carry out any extensive reformation of habitual criminals, it is obvious that many first offenders may be amenable to kindly treatment, provided that steps are taken to keep them from the contamination of hardened offenders. The new prison regulations, which are to come into force in England on April 1st, appear to have been framed with this object. Their effect may be briefly stated. There is to be a separate classification of selected convicts sentenced to penal servitude who on conviction are under 21 years of age. This classification is to be made by the directors of the prison. The judge who tries the case has nothing to do with it. The classification is as follows:—(*a*) selected convicts under 18 years of age who should be sent to a juvenile adult prison; (*b*) first offenders or persons not habitually criminal and who are considered eligible for the star class; and (*c*) ordinary convicts—i.e., habitual criminals, and so on. Provision is to be made for keeping these classes separate. It is to be the duty of the chaplain and the governor to endeavour to exercise personal influence over the convicts who are to receive education in the ordinary subjects of the elementary education code. They are also to be instructed in useful trades and industries which may fit them to earn a livelihood on release. It will be noticed that the principal effect of the rules above considered is to keep convicts under 21 years of age entirely separate from the hardened offenders. Convicts generally are dealt with in a second batch of rules by which it is provided that there shall be two divisions of penal servitude: "A" the ordinary division and "B" the long sentence division (for selected convicts who are sentenced to terms of more than ten years and who have served more than seven and a half years). All convicts in the ordinary division shall be classified by the directors immediately after conviction as follows—viz., (*a*) the star class; (*b*) the intermediate class; and (*c*) the recidivist (i.e., backslider) class. The classes will be kept apart as far as practicable. The star class is to consist of first offenders and persons who are not habitual criminals or of corrupt habits. Solitary confinement for not more than three months may be imposed upon members of this class. The intermediate class is to comprise first offenders whose general character and antecedents render them ineligible for the star class but who are not bad enough for the recidivist class The latter class is for hardened criminals and persons who have forfeited a ticket-of-leave. They may be confined alone for a period not exceeding nine months. Convicts in the intermediate class may be promoted or degraded. Convicts in the long sentence division shall, when practicable, be kept in a prison, or part of a prison, set apart for them. They are to wear a distinctive dress, will have their meals together, and may earn a good conduct gratuity, part of which may be spent by them on little luxuries while in prison, the remainder to be devoted to their benefit in such manner as the directors may prescribe. A convict in this division may be degraded to the ordinary division if he misbehaves. In our opinion the new rules are well calculated to give the first offender every chance, while they do not unduly ameliorate the conditions of the hardened criminal.

---

[1] Prager Medicinische Wochenschrift, 1904, No 52.

OBESITY AS A STIGMA OF DEGENERACY.

THE condition of general obesity is, according to the opinion of Professor E. Heinrich Kisch of Prague, not infrequently a noteworthy sign of hereditary degeneracy. He has carefully observed 488 cases of marked adiposity and records his results in the *Berliner Klinische Wochenschrift*, No 21, 1904. He states that in cases of hereditary obesity in females it is not uncommon to find a considerable development of hair on the upper lip, chin, and cheeks, even in quite young subjects, while young men of similar hereditary predisposition often approximate to the feminine type with scanty development of hair on the face. Further, he states that there is a tendency in such cases towards a condition of gigantism or early overgrowth and that in females there is frequently comparatively early commencement of menstruation, all of which conditions he regards as signs of degeneracy. He divides the cases observed by himself into four groups. The first group comprises 14 cases of very fat individuals, varying in age from nine to 16 years, eight being males and six females; in all of them the overgrowth of fat was marked from birth onwards. Some signs of degeneracy were present in every instance: in eight of the cases there was a general overgrowth in all directions, in nine cases deformities of the nasal septum, and abnormal development of the teeth in all of them. Three of the boys were distinctly feminine in type. The second group consists of 32 cases of the same character but of ages varying from 16 to 30 years, in all of whom the condition commenced in early childhood. There were 20 females and 12 males, all showing other evidence of developmental defects. All of the 12 men were somewhat of the feminine type—beardless or with very little hirsute growth on the face, very slight pubic development of hair, and breasts more like those of the female. Only four of the 20 women were of the male type. In eight of them there was early commencement of menstruation. 29 cases of this group showed small teeth badly developed. In nine there were abnormalities of the external ear. The third group comprised 213 cases, 106 males and 107 females, all with a hereditary predisposition to obesity but in whom the deposit of fat occurred later in life as the result of physiological or pathological conditions. In only 28 of these was any evidence of degeneracy forthcoming. In the fourth group there were 229 cases of acquired obesity, the result of errors of diet or nutrition, or of deficient exercise and other abnormal conditions, but in these cases there was no family predisposition and in only three of them were there any signs of hereditary degeneracy. We see, therefore, that in the first two groups in which the condition of excessive deposit of fat occurred in early life stigmata of degeneracy were present in every case, while in the third group the percentage of cases with such stigmata was only 13·2, and in the fourth group or the acquired cases the percentage was as low as 1·3. These observations of Professor Kisch are of considerable interest, since the causes of the development of obesity are somewhat obscure and any fresh facts tending to throw light upon them are of value. It is generally stated that the condition of obesity is hereditary in about half the cases and Professor Kisch's figures agree very closely with this statement. It is known, moreover, that in many situations of the body a condition of atrophy or degeneration is apt to be associated with a local deposition of fat in the organ, as, for example, around the muscle fibres in pseudo-hypertrophic paralysis and in the hilum of the kidney in chronic interstitial nephritis. Again, it is on record that an excessive deposit of fat is not uncommon in idiots and in some cases of chronic mental disorder and that it occurs sometimes in hysteria.

TORSION OF THE PEDICLE OF AN OVARIAN CYST IN A CHILD.

IN the *New York Medical Journal* of Dec. 17th, 1904, Dr. J. F. Erdmann has reported an interesting case of torsion of the pedicle of an ovarian cyst in a child. A girl, aged 13 years, was sent to him on Feb. 11th, 1904, by her medical adviser. She had had a number of attacks of abdominal pain which were supposed to be of appendicular origin. On Feb. 6th an attack began with vomiting and pain in the left side. The vomiting had continued almost daily but the pain at no time was referred to the region of the appendix. On palpation some pain was felt in the region of the appendix but considerably more in the vesical region and extending up to the umbilicus. The whole of the lower abdomen was rigid but the rigidity was especially marked in the region of the appendix. On rectal examination a mass could be felt. The temperature had ranged from 99° to 100° F. and the pulse from 98 to 130. On the day of examination the temperature was 100° and the pulse was 120. The abdomen was not markedly distended. A tentative diagnosis of disease of the appendix was made. On examination under ether a central mass which extended to the right was felt in the pelvis. The abdomen was opened and a gush of bloody serum took place. A dark blue tumour which fluctuated and resembled a dislocated and strangulated spleen, for which it was mistaken, was found. On breaking down some adhesions it was found to arise from the right ovary. Its pedicle was twisted, producing a gangrenous condition. The tumour was easily removed. The appendix was congested and was also removed. The abdomen was closed without drainage and recovery was uninterrupted.

THE OVERLYING OF CHILDREN.

Mr. Gibson, the Manchester city coroner, recently held four inquests on children who had died from suffocation and remarked that these tragedies were "the usual thing during the week-end." One of the cases occurred at the Manchester Maternity Hospital. The child had slept with his mother and Dr. E. Vipont Brown, who had made a careful examination of the body, said "the mother told him that she found the child lying on her arm with his face towards her body." As a result of this occurrence he stated that separate cots had been ordered. In answer to the coroner he said that it was a dangerous practice for children to sleep with their parents. Accidental suffocation was the verdict in all four cases. This was followed by a letter to the papers, dated Feb. 22nd, in which Sir W. J. Sinclair stated that he and his colleagues had come to the conclusion "that the use of cots would be more dangerous to the infants than lying alongside the mothers," as "the chief danger to the newborn with their low vitality arises from the difficulty in keeping them warm." If the mother is too ill to attend to the infant "a special cot is used padded with special materials ...... and supplied in addition with artificial heat." This at any rate shows that the child *can* be kept warm in a cot. But as indicating how unlike the wards of a hospital are to the homes in the "mean streets," where most of these deaths occur from the mothers being more or less drunk and too stupid or too tired to notice that the child they have with them in bed is being suffocated, the statement follows that "the wards are constantly patrolled by nurses and as a result we have no overlaying and no infant deaths from chilling and, of course, there is no abuse of alcohol." No one can doubt the admirable care and attention that have insured the safety of the children at the hospital even when in bed with the mothers but the conditions are wide as the poles asunder from those obtaining among the dwellers in the slums. This is recognised by Sir W. J. Sinclair who, however, considers that the lowering of vitality from cold, with probably also an unsatisfactory food-supply that would, he thinks, result from the use of cots, would bring about greater evils than those ensuing from the infants being in bed with their mothers. Sir W. J. Sinclair's letter drew one from Dr. Vipont Brown and another from Dr. Ernest E. Reynolds, both advocating the use of cots. The former considers that, apart from escaping the danger of being overlain, the cot insures purer air for the child and the important matter of more regularity as to feeding than when in bed with the mother. As to the difficulty of obtaining cots for the very poor a drawer placed on two chairs, an orange box, or a clothes' basket will make a fairly efficient substitute. Dr. Reynolds, in answer to Sir W. J. Sinclair's inquiry as to how the coroner "got to know" that it is "a dangerous practice for children to sleep with the mother," says that in Manchester alone it causes from 80 to 100 preventable deaths every year. He cites the following illustration. About 15 years ago, at his request, the Manchester board of guardians provided proper cots for all the infants in the workhouse hospital, as deaths from overlying had occasionally occurred. Since that time only one death from that cause has taken place. A woman, against the rule, took her child from the cot into her bed. 20 minutes later the nurse missed the child from the cot. The mother was asleep and the child was partially under her, quite warm but dead. Dr. Reynolds says that he has made for the late city coroner, Mr. Smelt, some dozens of post-mortem examinations of these cases. Fatigue, without the aid of alcohol, may cause sleep heavy enough to make the mother quite unconscious that she has rolled over on to the child or has drawn the clothes over its head, or death may arise from "suckling the child and falling to sleep, suffocating it by the heavy breast." He has known cases where the mother, going to get the husband's breakfast, has covered the child with the heavy bedclothes "to keep it warm" and has returned in half an hour only to find the infant dead. He quotes Dr. H. Ashby's weighty authority in favour of the cot and absolutely against an infant being allowed to share the mother's or the nurse's bed. Dr. Reynolds does not believe that there is any difficulty for even the poorest to have a cot "artificially warmed" if necessary. There are unfortunately dangers for the infant on either hand and the controversy turns on whether the danger from foul air, an insufficient supply of air, or from the prevention of breathing by the pressure of the woman's body—the squeezing out of his life—is greater or less than that from the depression of vitality caused by the infant being placed in a cot and so exposed to cold. The cold can be guarded against but the other danger cannot unless the wards are "constantly patrolled by nurses" which is possible in a hospital but not in a slum. A rejoinder from Sir W. Sinclair is chiefly notable as illustrating the misquotation from Butler, "He that's convinced against his will is of the same opinion still."

WORK IN THE TREATMENT OF NEURASTHENIA.

IN the *Boston Medical and Surgical Journal* of Jan. 12th Dr. H. J. Hall describes an interesting experiment in the treatment of neurasthenia by work and protests against the almost universal prescription of rest in this condition. He points out that these patients display mental peculiarities before the characteristic symptoms of the disease appear. They worry too much and over-estimate the importance of small things. To prolonged worry he attributes the disease. Treatment by rest is often successful but sometimes it is not because the absence of occupation is not conducive to mental quietude. Dr. Hall's idea was to provide a wholesome and pleasant occupation differing as much as possible from that which the patient previously followed which would conduce to "self-forgetfulness." As such patients are clever people with artistic tastes he started a shop for the manufacture of pottery and the hand-weaving of fabrics. The equipment consisted of some half-dozen looms, spinning wheels, vats and dyes for colour work, a kiln for baking and glazing pottery, and a potter's wheel. A competent teacher was secured and when the shop was working and turning out articles a few patients suffering from a mild form of neurasthenia were introduced for a short time each day. The shop at once became popular and had a very encouraging effect on the patients. Subsequently basket-making was introduced and proved very useful. The work done was very good and to the resulting satisfaction of the patients Dr. Hall partly attributes its beneficial effect. The next step was to introduce patients affected with a more pronounced degree of neurasthenia. The difficulty was to eliminate the fatigue and the irritation which even the anticipation of change of task induces in these patients. The treatment was begun by rest in bed for a few days or a week. Then without any warning whatever the patient was ordered to do something simple, perhaps only to sit up in bed for a short time. The order given was changed from day to day. Then the patient was sent to the shop where he worked for gradually lengthening periods daily. Many discouragements occurred and constant tact and vigilance were required but the results were good. After a few weeks of work the inertia of months and years was thrown off and the change in facial expression, in skill of movement, and in the whole morale of the patient was *remarkable. Although the work appealed* especially to people who had never done physical work and to whom the pleasure of manual work was a revelation it was particularly appreciated by those of limited means who felt that they were acquiring a useful trade by which they might support themselves if they could not return to their old life. To encourage a feeling of independence, when the patient turned *out a work of* value it was sold and he received the proceeds. It was surprising how the patients' lives readjusted themselves and how the petty annoyances and troubles again took their proper subordinate position. Dr. Hall also suggests *this plan of treatment* as a prophylactic measure. After he began to write his paper he ascertained that a similar method of treatment has been carried out *successfully at Zürich* by a layman named Grohmann who works under the direction of physicians.

THE ROYAL COMMISSION ON THE CARE AND CONTROL OF THE FEEBLE-MINDED.

Dr. *James Craufurd* Dunlop has been appointed an *additional member of this Commission*. This makes the second additional medical member who has been appointed *since we pointed out in* THE LANCET *of Sept. 17th, 1904*, that only one medical man, Dr. Frederick Needham, had been nominated to a seat on a Commission which *has to deal* with a subject so full of intricacy and responsibility. It will be remembered that the other medical member appointed was Dr. H. B. Donkin. Dr. Dunlop is assistant to the medical adviser to the Commissioners under the Prisons (Scotland) Act, 1877, at the Department of Prisons and Judicial Statistics, Edinburgh, and he is also superintendent of statistics in the Registrar-General's Office, Scotland, having succeeded to that post on the death of Dr. R. J. Blair Cunynghame which occurred in December, 1903. The *Times* states that no period can yet be specified for continuing the sittings of the Commission, the first of which was held in October last.

CHELSEA CLINICAL SOCIETY.

As briefly mentioned in our issue of March 4th the annual clinical debate, the subject being Chronic Constipation and its Medical and Surgical Treatment, will be held at the Chelsea Dispensary, Manor-street, King's-road, London, S.W., on March 14th and 21st at 8.30 P.M. On March 14th the speakers will include Mr. W. Arbuthnot Lane, Dr. T. Vincent Dickinson (the president), Dr. J. Foster Palmer, and Dr. W. H. Goddard. On March 21st the speakers will include Dr. William Collier, Dr. F. J. Smith, Dr. H. Campbell Thomson, and Dr. Leonard L. B. Williams. These meetings are open to all members of the medical profession.

A SPECIAL meeting of the Laryngological Society of London will be held at 20, Hanover-square, W., at 3 P.M., on Friday, March 17th. There will be an exhibition of pathological specimens on view from 2 P.M. in connexion with the attendance of many eminent foreign laryngologists who are coming to London for the Garcia centenary. Cases will be shown by Mr. H. Barwell, Dr. H. J. Davis, Dr. Dundas Grant, Dr. H. L. Lack, Dr. E. Law, Dr. W. Milligan, Mr. C. A. Parker, Mr. H. B. Robinson, Mr. P. R. W. de Santi, Sir Felix Semon, Mr. Charters J. Symonds, Dr. H. Tilley, Dr. StClair Thomson, Dr. Atwood Thorne, and Dr. P. Watson Williams. Professor Glück of Berlin will give a special demonstration on Saturday, March 18th, at 20, Hanover square, at 2 P.M., of his method of removal of the entire larynx, to which *surgeons specially* interested in the subject are cordially invited.

THE medical officer of health of the Cape Colony states that for the week ending Feb. 11th the condition of the *colony as to plague* was as follows. No case of plague in man was *reported throughout* the colony but plague-infected rodents *were discovered at* Port Elizabeth and at East London. Other districts of the colony were *free from plague* of any kind. As regards Hong-Kong *a telegram received at* the Colonial Office on Feb. 27th states that for the week ending Feb. 25th there were 2 cases of plague and 2 deaths from the disease. As regards the *Mauritius there were* 2 cases of plague for the week ending March 2nd and 2 deaths from the disease.

THE Executive Committee of the General Medical Council, which met on Monday, Feb. 27th, at the offices of the Council, received some interesting tables showing the results of the latest competitions held for commissions in the Medical Departments of the Navy, the Army, and the Indian service. The tables show well the successful position enjoyed by the diplomates of the London Conjoint Board. The committee appointed Professor Howard Marsh, professor of surgery in the University of Cambridge, to act as inspector of the surgical examinations of the University of Edinburgh

Sir Patrick Manson will take the chair at the dinner to be given on Wednesday, April 5th, to Mr. W. Johnson Smith by the medical staff of the Seamen's Hospital Society. Mr. Johnson Smith is retiring after 36 years' service and it is hoped that most of his old friends and colleagues will be able to be present on this occasion. Dinner tickets and all information respecting the dinner can be obtained from the honorary secretary to the dinner committee at the offices of the Seamen's Hospital Society, 13A, Cockspur-street, London, S.W.

AT the twenty-eighth annual meeting of the Irish Medical Schools' and Graduates' Association, to be held on March 18th, Surgeon-General C. Sibthorpe, C.B., will resign the presidential chair to Sir William Whitla who will preside at the festival dinner to take place the same evening at the Hotel Cecil, at 7.30 P.M. All communications should be addressed to Mr. E. Canny Ryall, 30, Harley-street, London, W.

AT the Royal Sanitary Institute, on Saturday, March 25th, at 11 30 A.M., a *discussion* will be opened on Municipal Milk Depôts and Milk Sterilisation by Dr. G. F. McCleary, medical officer of health of Battersea. The chair will be taken by Sir Shirley F. Murphy. In the afternoon visits will be made to the Battersea municipal milk depôt, disinfecting station, public mortuary, coroner's court, and shelter.

His Majesty the King gave a dinner party at Buckingham Palace on Saturday, March 4th. Amongst those who had the honour of receiving invitations were Sir William S. Church, Bart., President of the Royal College of Physicians of London, and Mr. John Tweedy, President of the Royal College of Surgeons of England.

BY the courtesy of the general secretary of the British Medical Association we have been favoured with an advance proof of the report of the Conference on Hospital Administration between representatives of the Association and of hospital boards which was held in the Board Room of the

Metropolitan Asylums Board on March 2nd. Next week we hope to deal at length with the matter.

Sir Frederick Treves, Bart., K.C.V.O., C.B., has been promoted to Knight Grand Cross of the Royal Victorian Order.

THE CONTROL OF HOSPITAL EXPENDITURE WITH EFFICIENCY.

AT a meeting of the Hospitals Association held at Charing Cross Hospital on March 3rd Dr. DONALD J. MACKINTOSH, M.V.O., medical superintendent of the Glasgow Western Infirmary, read an interesting and instructive paper upon the above subject. Mr. THOMAS BRYANT presided.

Dr. MACKINTOSH said that for the past 20 years he had devoted his attention to the study of hospital construction and administration. Taking the comparison per occupied bed as the only fair and possible unit of comparison he found from reference to "Burdett's Hospitals and Charities Annual" that the difference in 1903 between the London hospitals and those of the provinces was very striking. It ranged in hospitals with medical schools from £50 5*s.* in Dundee to £142 15*s.* in St. George's Hospital, London. In order that this difference might be accounted for a minute account of details should be made. He laid down as one of the first conditions of effective hospital management that the accounts should be kept in such a way that even a layman might be able at any time to see what was spent on *each* item in each *separate* department. This condition could be fulfilled only if another condition was also satisfied—viz., that the whole work of superintending the various departments should be focussed in the hands of a single administrator directly responsible for the institution to the board of managers. Accounts should be kept showing the exact expenditure day by day in each department of a hospital in order that there might be no difficulty in finding out whether there was waste or extravagance in a particular department or whether that waste, if it existed, was in the wards or in the nurses' or servants' departments. At the Glasgow Western Infirmary they did not manufacture certain drugs which he understood was the practice in some of the large London hospitals. He believed that such drugs could be purchased more cheaply from large manufacturers. Enonomy in the use of dressings was obtained by a system of entering into a book one day the materials required by a particular surgeon for use the following day. This book was examined in the superintendent's office. The system was worked by a staff consisting of a clerk and a typist. He doubted whether the detection of unusual expenditure under this heading would be possible to a lay superintendent. A similar system was adopted with regard to crockery and breakages from carelessness were easily detected. In considering the question of lighting and heating it was necessary to study the comparative cost of coal in different parts of the country and the quality of the fuel and the amount used. In the Glasgow Western Infirmary large boilers were used for generating steam and this steam was utilised for heating, cooking, working lifts, working a laundry which turned out every week over 20,000 articles, and by means of the same boiler power they generated electricity for use in the infirmary, not only for lighting the building but the grounds and, in addition, kept going a number of electric ventilating fans and electric lamps for the treatment of lupus. A record was kept of the work done by each engine in every hour of the day and night and also of the boiler pressure, the steam pressure, the temperature of the engine room, the amount of fuel consumed, and the amount of ashes removed. The electric current was generated at a lower cost than would be possible if taken from the public mains. As a matter of fact, it cost 1*d.* per unit for everything, while if taken from the corporation mains it would cost 3½*d.* for lighting and 1*d.* for motive power. It was possible that certain advantages might follow from the combination of the smaller hospitals in the purchase of goods but as regarded the larger hospitals the most economical and effective method was to make use of the information and guidance of experts who were members of hospital boards. Every large hospital should at all times be free to purchase its goods in the open market. But, after all, economy in purchase was only one aspect of the problem. Economy in use was probably of even greater importance. And this could be secured only by means of constant supervision.

A discussion followed in which Mr. THIES (secretary of the Royal Free Hospital) pointed out the differences between hospitals in Scotland and in London as regards the payment of rates and the cost of lighting and fuel.—Mr. SYDNEY HOLLAND, while agreeing in the main with the remarks of Dr. Mackintosh, said that the question as to whether the administrative head of a hospital should be the secretary or not depended upon the size of the hospital. If large it was absolutely necessary to subordinate the management to the heads of the various departments.—Sir HENRY BURDETT spoke in favour of the appointment of a superintendent for administrative purposes and a secretary for financial work.—Mr. WILLIAM MORTON pointed out the relation between economy of administration and the size and shape of the hospital buildings.—Dr. MACKINTOSH briefly replied and the meeting terminated with a vote of thanks to the chairman.

MEDICINE AND THE LAW

Frost v. *the Aylesbury Dairy Company.*

IN a leading article published in THE LANCET of Nov. 12th, 1904, p. 1361 [illegible] tion we commented upon the attitude [illegible] judge who tried the case with regard to the use by the defendants of the well-known title of their firm. This his lordship appeared to regard as a kind of false pretence on their part because their milk-supply is not now drawn from the Aylesbury district, as formerly it was, and we observed that it would be interesting to hear what the Court of Appeal would say upon this point. We were not wrong in our suggestion that the Court of Appeal would not agree with Mr. Justice Grantham, for in delivering recently their judgments upon the defendants' appeal both the Master of the Rolls and Lord Justice Mathew expressed in plain terms their dissent from his view, the former saying that in his opinion it was unfortunate that such observations had been made. In his opinion "there was not the shadow of a foundation for any aspersion on the defendants in connexion with their bearing the name of 'The Aylesbury Dairy Company.'" Lord Justice Mathew, in dealing with this topic in the course of his judgment, said that there was no reason whatever for any reflection upon the defendants. They had imposed stringent conditions upon the farmer from whom they obtained the milk in question but it was obviously impossible, where their supply was drawn from different parts of the country, to see that each farmer complied in every respect with their conditions and requirements. His lordship, in the words of the *Times* report, "regretted that the use of the word 'Aylesbury' in the name of the defendant company was reflected upon by the learned judge (Mr. Justice Grantham). He desired to say that he did not concur in those reflections and in his opinion the defendant company came well out of the inquiry." With these observations we entirely concur; we have no doubt that the stringency of the regulations imposed by the Aylesbury Dairy Company upon the farmers who supply them enables them to provide as pure milk for their customers as any to be found in the country and to set an example of what the ordering of dairy farms should be. In this particular instance they have been held liable because all purveyors of food, and in any case a firm who advertise it as of exceptional purity, are responsible if from any cause it should not be fit for the purpose for which it is purchased. This issue was not affected by the unusual and surprising strictures of Mr. Justice Grantham upon the trade name under which the milk was sold and the Court of Appeal apparently held that as the words used did not constitute a misdirec [illegible] oint of law as to which the jury had to be [illegible] ot of such a nature as to entitle the defendants to a new trial. We would, however, point out that they were irrelevant and undeserved remarks, extremely likely to prejudice the jury in its decision upon the difficult and closely contested question of fact upon which the whole issue of the trial hung. The important issue in the trial was not whether the dairy company warranted its milk to be pure but whether the typhoid fever from which the plaintiff's wife died was due to the company's milk or to some other cause. As to this there were expert opinions on both sides and a considerable conflict of evidence and it is difficult to say with confidence that the [illegible] Juries are easily misled by [illegible] regretted that the learned judg[illegible] have weighed his words before giving free utterance to a hastily conceived and ill-founded opinion. It is also a hardship upon the defendants that they should have to pay damages which may be wholly or partly due to the judicial aspersion in question.

The Unlawful Detention of Medical Men.

As recently as Feb. 18th attention was called in THE LANCET[1] to an extraordinary case of the imprisonment of an obstetric assistant, sent out from the London Hospital, by the relatives of a parturient woman, whose friends forcibly kept the medical man in the house to await her labour and until it was completed. An experience of a similar description, also among aliens of the lower class, was recently the lot of another member of the staff of the same hospital. In this instance Mr. R. V. Dolbey, the resident accoucheur at the hospital, visited the patient and finding everything normal was about to leave one of his juniors to deal with it, when the women present proceeded to resist his departure and called in three men to help them. These commenced to use physical force in order to detain him and if this circumstance placed him in a [illegible] had the fortunate [illegible] l with the case by [illegible] Samuel Woolfson, [illegible] ith hard labour for assault. An offence committed against a medical man or a nurse administering aid as an act of charity among the suffering poor will strike even those whose experience is of [illegible] feature in hospital work of [illegible] l that two such acts should [illegible] weeks of one another in the [illegible] r worse. It was, however, stated on bel[illegible] ndon Hospital that difficult[illegible] ing with our countrymen [illegible] with aliens. Presumably they are largely due to ignorance of the intentions of the medical man, of the nature of the charity on behalf of which he acts, and of the power of the law to punish an attack upon him, and the suggestion may be repeated which was made in THE LANCET of Feb 18th that a full account of the penalty which has now been inflicted, with perhaps an explanatory note as to the position filled by the hospital in the life of the poor, if printed in Yiddish and freely distributed or handed to applicants for hospital assistance, might do much to prevent such occurrences in future. However downtrodden the humbler class of Jew may find himself in the Czar's dominions the position of his [illegible] if the treat- [illegible] companions [illegible] ermissible in Russia.

HINTS ON INCOME-TAX ASSESSMENT.

THE time is approaching when each member of the medical profession will receive a document from the Inland Revenue authorities inviting him to make a return of his income for purposes of taxation. To the man who is familiar with accounts or whose income is so large that he can afford to employ an accountant to make out his return this event is not of much concern. Members of the medical profession, however, are not always versed in the mysteries of bookkeeping. It is proposed to give an outline of the [illegible] er should adopt in arriving at [illegible] liable to pay 1s. in the £. It should be stated at the outset that there is no necessity to send in the calculations upon which the return is based. Where, however, the Commissioners challenge the return it may be convenient for the practitioner to be able to produce his figures.

Basis of the Tax.

Income tax is charged upon the profits of a practice, estimated upon a fair average of three years. This period ends either (*a*) on that day of the year immediately preceding the year of assessment on which the accounts are usually made up; or (*b*) on April 5th preceding the year of assessment. It follows that in order to estimate the income tax payable on Jan. 1st, 1905—i.e., the tax for the income of 1904—regard should be had to the average profits of the years 1901, 1902, and 1903. As accounts for the year are often made up to April 5th the period may run from April 5th, 1901, to April 5th, 1904. Where the practice was commenced within the period of three years the average income for the purposes of income tax is arrived at by taking the average yearly profit from the date of commencing practice. Suppose, for instance, the practice was commenced on April 5th, 1902, and £1000 were made in 1902 and 1903, the profit for the purposes of income tax would be £500 (subject, of course, to the deductions hereinafter referred to). If the practice was commenced within the year of assessment—i.e., 1904—the profits are to be estimated according to the best of the practitioner's knowledge and belief. The grounds upon which the estimate is based must, if required, be stated for the information of the Commissioners.

Income which must Not be taken into Account.

When he receives his "yellow form" the practitioner will do well to make no entry upon it which does not relate to his professional receipts. Income which is received *aliunde* is not to be entered. Thus income which comes under any of the following heads must not be entered: (*a*) income from any office or employment in the public service or under any public body, or any annuity, &c., *payable out of public revenue*; (*b*) the salary of a medical officer of health and the fees of a public vaccinator (these are taxed under Schedule E and should not be entered on the yellow form); (*c*) any income derived from ownership or occupation of land or unfurnished houses or bu[illegible] in[illegible] [N[illegible] in[illegible] en[illegible] if[illegible] (See sub title, "Exemptions," *infra*.) The income of a person resident in the United Kingdom which is earned abroad and which is not brought, remitted to, or received in, the United Kingdom need not be entered.

Exemptions.

If the income does not exceed certain specified amounts exemption or abatement is allowed. Thus: (*a*) total exemption may be claimed when the income from all sources does not exceed £160 per annum; (*b*) abatement of duty on £160 may be claimed when the income exceeds £160 but does not exceed £400; (*c*) abatement of duty on £150 may be claimed when the income exceeds £400 but does not exceed £500; and (*d*) abatement of duty on £120 may be claimed when the income exceeds £500 but does not exceed £700. For the purpose of estimating "income" in order to obtain an abatement the claimant must set forth every source whence the income is derived with the amount derived from each source. Where income is derived from a profession, office, or employment he must state the nature and particulars thereof and where carried on. In this connexion it is to be noted that for the purpose of claiming abatement or exemption income *from every source* is to be entered—i.e., income from investments, public offices, &c. The practitioner who, on looking through his books, finds that his "average income" is something over £700—say £800—must not rashly assume that he is not entitled to any abatement. He may find that when he has made the deductions from gross income which are allowed by law his true income (for the purposes of taxation) will be less than £700. Similarly, a man earning £200 may find that, after deductions have been made, the true income is below £160 and that he is therefore entitled to complete exemption.

How the Profit is Ascertained.

Income tax being, as has been stated, a tax upon the profits of a profession, certain deductions must be made from income in order to arrive at the profit. The practitioner will naturally look into his books to see what his income has been for the last three years. Such books will disclose the gross receipts. Leaving debts (whether good or bad) out of account for the moment the following deductions may be made from gross receipts: 1. Money expended upon the repair of any premises occupied by the practitioner in connexion with his practice. 2. Money expended upon the supply of drugs and the supply and repair of implements and utensils not exceeding the sum usually expended for such purposes according to the average of the three years preceding. Under the heading "repairs of premises" may be included any repairs at a dispensary or the consulting room. The cost of improvements, however, could not be deducted under this head. For instance, the enlargement of a dispensary would hardly come within the word "repair." The amount to be deducted for repairs and implements is to be calculated on the average of three years. So, if £100 worth of drugs and implements were purchased in 1903 and no other drugs or implements in the two previous years the deduction should be £33 6*s.* 8*d.* 3. The rent of premises used solely for the purposes of business and not as a place of residence (e.g., a dispensary). 4. If the practitioner resides in the house where he carries on his practice he is entitled to deduct a proportion, not exceeding two-thirds, of the rent which he pays for the house. 5. Any other disbursements or expenses wholly and exclusively laid out for the purposes of the practice Under this head it is conceived that the practitioner may deduct: (1) the entire cost of keeping horse and carriage or motor, including the cost of repairs, provided such horse and carriage or motor is used exclusively in the practice. (Where, however, it is used to a large extent by the practitioner's wife, or for private purposes, the entire cost of upkeep could not be deducted. Opinions differ as to the amount which may be deducted in such a case. Probably the best course for the practitioner to adopt is to deduct the whole cost and let the Inland Revenue authorities raise the question if they think proper.) Inasmuch as the purchase of a horse and carriage or motor involves an outlay on capital account it is submitted that an annual charge for depreciation might also be made; (2) the salary of any assistant, nurse, or secretary whom he may employ exclusively for the purposes of his practice; (3) the wages of any servant employed exclusively for the practice, such, for instance, as a coachman or chauffeur, and the board of any such servant (if paid by his master); (4) travelling expenses incurred in the course of visits to patients; (5) cost of heating and lighting surgery or consulting room; (6) cost of telephone. telegrams, stationery, and stamps (including receipt stamps); (7) cost of cleansing professional premises and such part of a private residence as is used for professional purposes; (8) rates on such proportion of a private residence as is used for the purposes of the practice and all the rates paid in respect of premises exclusively used for professional purposes; (9) annual subscriptions to medical societies, medical protection societies, &c; (10) law costs incurred in recovering debts; (11) cost of bottles, &c., used in the dispensary; and (12) losses accruing from any accident happening in the conduct of the practice—e.g., a carriage accident or injury while operating, unless such loss is covered by insurance.

---

[1] THE LANCET, Feb. 18th, 1905, p. 434.

Deductions not Allowed.

The following is a list of expenses which *may not* be deducted:—(*a*) interest on capital, or any annual interest, or any annuity, or other annual payment payable out of the profits or gains. For instance, suppose a man purchased a practice for £1000 to be paid off out of the profits of the practice by five instalments of £200. These instalments cannot be deducted. Similarly, if a man purchases a practice for £1000, which he borrows at 4 per cent., he cannot deduct £40 a year for interest; (*b*) any sums invested or employed as capital or on account of capital withdrawn from the practice. For instance, money spent in buying out a retiring partner, or in purchasing a motor-car could not be deducted; (*c*) any sums expended in improvement of premises, or written off for depreciation of land, buildings, or leases; (*d*) any loss not connected with, or arising out of, the practice; (*e*) any expenses of maintenance of the practitioner, his family, or establishment; (*f*) any loss recoverable under an insurance or contract of indemnity: (*g*) any sum paid as income tax on profit or gains, or on the annual value of trade premises; (*h*) any premium for life insurance (but an allowance upon this head may be made as set out below); and (*i*) educational expenses, such, for instance, as lecture fees, or fees for attending classes in order to take out a diploma of public health.

How Debts are to be Treated.

Good debts appearing in the books to be due to the practitioner may be entered amongst gross receipts, care being taken that they are not brought into account as cash receipts when actually paid. Bad debts, if proved to be bad to the satisfaction of the Commissioners, may be deducted. With regard to doubtful debts, a deduction may be made according to their estimated loss or deficit.

Insurance Premiums.

Insurance premiums are not treated as business expenses for purposes of deduction but are dealt with separately. After all the foregoing deductions have been made the resulting figure is entered upon the yellow form. From this amount a deduction may be claimed for life insurance premiums actually paid. The amount so paid must be entered up in the proper place on the form and the claimant must be prepared to produce the insurance company's receipt if required. The allowance claimed must not exceed one-sixth of the claimant's net personal income from all sources. It is important to notice in this connexion that it is only premiums paid to an English insurance company or to an approved Colonial company which may be deducted. Thus a premium paid to an American or other foreign company would not be allowed for.

The Profits of a Partnership.

Hitherto we have only dealt with questions which arise in relation to the income tax of a single practitioner. The principles above enumerated also apply where the profits of a practice are divided among two or more partners. Certain questions arise, however, in relation to the assessment of a partner or partners which must not be overlooked. In the first place, the computation of duty for the partnership should be kept distinct from any other duty chargeable on the members separately. A return made by the senior partner resident in Great Britain is sufficient to satisfy the authorities. A separate return must not be made in respect of the return of any partner unless he desires to claim an abatement. Thus, suppose the share of a partner in the proceeds of the practice did not exceed £500, it would be worth his while to claim an abatement. He may do so by filling in the form of declaration which is to be found in the yellow form. Suppose there is a change in the partnership either by reason of the death or retirement of a partner, or owing to the admission of a new partner, within the period of three years. In such a case annual profit must be estimated upon the average of three years, unless it be shown to the satisfaction of the Commissioners that the profits have fallen short, or will fall short, from some specific cause to be alleged to them and proved since such change or succession took place or by reason thereof. For example, suppose the senior partner had some special knowledge which enabled him to earn the largest proportion of the partnership income. His demise might reduce the annual profits to a very small figure. It is anticipated that upon a fact of this kind being proved to the Commissioners a reduction would be made.

Looking Back.

THE LANCET, *SATURDAY*, March 10, 1827.

ARTIFICIAL PUPIL.

Case of a Lady born Blind, who received Sight at an advanced age by the formation of an Artificial Pupil. By James Wardrop, Esq., F.R.S. Edinburgh, Surgeon Extraordinary to the King, &c.

[*From the Philosophical Transactions.*]

READ BEFORE THE ROYAL SOCIETY, JUNE 15, 1826.

As imperfections in the original structure of our organs of sense, which are remediable by art, are extremely rare, and as cases of successful operations on these organs essentially contribute to illustrate their functions, as well as to throw light on the operations and development of the human mind; the following instance of vision being imparted to a lady born blind, by an operation at an advanced period of life, will, it is hoped, not be considered unworthy of being submitted to the consideration of the Royal Society.

The case, besides establishing the curious physiological fact, that the nerve of the eye can remain fit to receive the impressions of external objects, though totally excluded for a long series of years from the performance of that function, claims a much higher interest in a philosophical point of view; some of the facts here detailed confirming in a remarkable manner what **BERKLEY** had predicted of "a man born blind being made to see," in the 79th Section of his "New Theory of Vision," published in the year 1709. He says, "a man born blind being made to see, would, at the first opening of his eyes, make very different judgments of the magnitude of objects intromitted by them from what others do. He would not consider the ideas of sight with reference to, or as having any connexion with, the *idea* of touch." It may also be observed, that in the present case the blindness was more complete, and the period at which vision was acquired was much later in life, than in any instance which has hitherto been recorded.

The lady, whose case forms the subject of this paper, was observed, during the first months of her infancy, to have something peculiar in the appearance of her eyes, and an unusual groping manner, which made her parents suspect that she had defective vision. When about six months old, she was placed under the care of a Parisian oculist, who performed an operation on both her eyes, with a view to afford her sight. The operation on the right eye was, however, followed by violent inflammation, and a collapse of the eyeball, thus causing a complete destruction of the organ of vision. The operation on the left eye, though equally unsuccessful in attaining its object, was not followed by any alteration in the form or size of the globe. From the account stated by her friends, it was impossible to form any correct notion of the state of her eyes previous to the operations which were performed. It seems, however, extremely probable that the blindness, which was attempted to be remedied, had been produced by congenital cataracts, and that these operations had for their object the removal of the opaque lenses.

From the above early period she had continued totally blind, being able merely to distinguish a very light from a very dark room, but without having the power to perceive even the situation of the window through which the light entered; though in sunshine or in bright moonlight she knew the direction from whence the light emanated. With regard therefore to the degree of sight, this lady was more completely blind than the boy in the celebrated case related by Mr. Cheselden, in the 35th vol. of the Transactions of the Royal Society; for in that instance the boy knew black, white, and scarlet apart from one another; and when in a good light he had that degree of sight, which generally continues in an eye affected with cataract; whereas in this lady, the pupil being completely shut up, no light could reach the retina, except such rays as could pass through the substance of the iris.

When she was placed under my care, she had reached her 46th year. The right eye-ball was collapsed, but the left retained its natural globular form. The cornea of this eye was transparent, except at one point near its circumference, where there was a linear opacity, which had probably been the cicatrix of the wound made during the operation in her infancy. The anterior chamber of the eye was of its natural capacity, but I could not distinguish any vestige of a pupil, some streaks of yellow lymph being deposited in irregular manner over the central part of the iris. There was every reason to believe the retina was sound; for though she could not perceive objects, nor had any notion of colours, yet the circumstance already mentioned of her being able to distinguish between a very light and a very dark chamber and between a gloomy day and sunshine, rendered it probable that the nerve was in a sound and natural state. Under this impression, I thought that the restoration of her sight, by making an artificial pupil, was practicable, and certainly well worthy of a trial. Accordingly, on the 26th of January, I introduced a very small needle through the cornea, passing also through the centre of the iris; but I could not destroy any of the adhesions which had shut up the pupillar opening. After this operation she said she could distinguish more light, but she could perceive neither forms nor colours. The result of this first attempt justified the favourable views entertained of the state of the retina, and Mr. **LAWRENCE**, who at this time was consulted, coincided with me in this opinion.

On the 8th of February, a second operation was performed, which consisted in passing a sharp-edged needle through the sclerotica, bringing its point through the iris into the anterior chamber, repassing it into the posterior chamber at a small distance, and then dividing the portion of iris thus included between the two perforations of the needle. Only a very slight inflamation followed,—the light became offensive to her,—she complained of its brightness, and was frequently observed trying to see her hands; but it was evident her vision was very imperfect; for although there was an incision made in the iris, some opaque matter lay behind this opening, which must have greatly obstructed the entrance of light.

On the 17th of February, a third operation was performed, which consisted in still further enlarging the opening in the iris, and in removing the opaque matter, by a needle introduced through the sclerotica. This was followed by a very slight degree of redness.[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8746 births and 5123 deaths were registered during the week ending March 4th. The annual rate of mortality in these towns, which had been 17·4, 17·3, and 15·7 per 1000 in the three preceding weeks, rose again to 17·1 per 1000 last week. In London the death-rate was 17·1 per 1000 and it also averaged 17·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 8·4 in Grimsby, 9·6 in Aston Manor, 10·0 in Smethwick, 10·3 in Walthamstow, 10·5 in Hornsey and in Rotherham, and 10·7 in Northampton; the highest death-rates were 21·9 in Stockton-on-Tees, 22·0 in Liverpool, 22·2 in Reading, 22·9 in Sunderland, 23·4 in Nottingham, 24·3 in Tynemouth, and 29·7 in Merthyr Tydfil. The 5123 deaths in these towns last week included 486 which were referred to the principal infectious diseases, against 401, 410, and 365 in the three preceding weeks; of these 486 deaths, 190 resulted from measles, 105 from whooping-cough, 86 from diphtheria, 46 from diarrhœa, 34 from scarlet fever, 24 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases was registered last week in Willesden, Bournemouth, Great Yarmouth, Norwich, Walsall, Handsworth (Staffs.), Grimsby, Wallasey, or Bury; while they caused the highest death-rates in Portsmouth, Southampton, Reading, Hanley, West Bromwich, Nottingham, and Newport (Mon.). The greatest proportional mortality from measles occurred in Portsmouth, Southampton, Reading, West Bromwich, Nottingham, Stockton-on-Tees, Newport (Mon.), and Merthyr Tydfil; from scarlet fever in Rochdale and Blackburn; from diphtheria in West Ham, Ipswich, West Hartlepool, and Newport (Mon.); from whooping-cough in Hanley, Bradford, and Rotherham; and from diarrhœa in West Bromwich and Newport (Mon.). The mortality from "fever" showed no marked excess in any of the large towns. One fatal case of small-pox was registered in Leeds but none in any other of the 76 towns. The number of small-pox cases under treatment in the Metropolitan Asylums Hospitals, which had been nine, eight, and 15 at the end of the three preceding weeks, were again 15 at the end of last week; four new cases were admitted during the week, against one, three, and seven in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2002, against 2077, 2017, and 1987 at the end of the three preceding weeks; 290 new cases were admitted during the week, against 260, 241, and 224 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 400, 378, and 335 in the three preceding weeks, rose again to 353 last week, but were 18 below the number in the corresponding period of last year. The causes of 74, or 1·4 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Leeds, Hull, and in 43 other smaller towns; the largest

learn."

41 deaths from scarlet fever were slightly below the corrected average number; among the various metropolitan boroughs the greatest proportional fatality from this disease was recorded in Fulham, St. Marylebone, Shoreditch, Bethnal Green, Southwark, and Greenwich. The fatal cases of diphtheria were 53 last month, against an average of 144 in the corresponding quarters of the ten preceding years; this disease was proportionally most fatal in Hammersmith, Fulham, Shoreditch, Stepney, Poplar, and Southwark. The 136 deaths from whooping-cough were 72 below the corrected average number; among the various metropolitan boroughs the highest death-rates from this disease were recorded in Kensington, Hammersmith, Fulham, Shoreditch, and Southwark. The 15 fatal cases of "fever" showed a decline of 30 from the average number in the corresponding quarters of the ten preceding years; the greatest proportional mortality from enteric fever occurred in Chelsea, Hackney, Battersea, Wandsworth, Deptford, and Woolwich. The 55 deaths from diarrhœa were equal to the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, Stepney, Southwark, Bermondsey, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was nearly 43 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 113 per 1000. The lowest rates of infant mortality were recorded in Paddington, Fulham, Shoreditch, Lambeth, and Wandsworth; and the highest rates in St. Pancras, the City of London, Bethnal Green, Poplar, and Southwark.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon J. Menary to the *Good Hope*, on recommissioning, to date Feb. 28th. Staff Surgeons: R. S Bernard to the *Terrible*, to date Feb. 28th; and A. G. W. Bowen to the *Amethyst*, undated. Surgeons: A. Woollcombe to the *Pandora*, undated; J. H. McDowall to the *Good Hope*, to date Feb. 28th; and F. R. Mann to the *Firequeen*, to date March 6th.

ROYAL ARMY MEDICAL CORPS.

Lieutenant G. F. Rugg is seconded for service with the Egyptian Army (dated Feb. 10th, 1905).

The undermentioned Majors to be Lieutenant-Colonels (dated Jan. 31st, 1905):—J. R. Forrest, Brevet Lieutenant-Colonel M. W. Russell, G. E. Moffet, H. A. Haines, G. E. Hale, D.S.O., C. W. Johnson, A. T. I. Lilly, C. C. Reilly, A. De C. Scanlan, W. Turner, W. E. Berryman, S. E. Duncan, and R. Caldwell.

The undermentioned Majors are placed on retired pay (dated Jan. 31st, 1905): B. F. Zimmermann, A. Stables, J. D. Moir, R. Crofts, D.S.O., H. D. James, and G. M. Dobson.

Lieutenant S. M. Adye-Curran to be Captain (dated Nov. 28th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Shropshire and Staffordshire: Surgeon-Lieutenant-Colonel E. Cureton is granted the honorary rank of Surgeon-Colonel (dated March 8th, 1905). 1st Worcestershire: Surgeon-Lieutenant G. H. Rutter to be Surgeon-Captain (dated March 8th, 1905). 1st Monmouthshire: John O'Keefe to be Surgeon-Lieutenant (dated Feb. 25th, 1905).

Rifle: 3rd Volunteer Battalion the Royal Fusiliers (City of London Regiment): James Searson to be Surgeon-Lieutenant (dated March 8th, 1905). 2nd Volunteer Battalion the King's (Liverpool Regiment): Supernumerary Surgeon-Lieutenant J. G. Martin to be Surgeon-Captain and to remain Supernumerary (dated March 8th, 1905). 18th Middlesex: Surgeon-Lieutenant-Colonel C. Godson is granted the honorary rank of Surgeon-Colonel (dated Feb. 25th, 1905). 7th Middlesex (London Scottish): Surgeon-Lieutenant A. H. Pirie to be Surgeon-Captain (dated Feb. 21st, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Aberdeen Company: Lieutenant D. Rorie, from the Black Watch Bearer Company, to be Lieutenant (dated March 8th).

THE WAR IN THE FAR EAST.

The stupendous struggle between the vast armies under General Kuropatkin and Marshal Oyama remains at an acute stage as we go to press. Enough is known to make it clear that a terrible drama of death and of anguish worse than death is being enacted, but for the time being no more can be said with certainty.

A report has been published by General Trepoff, chief medical officer of the Manchurian Army, giving particulars of the officers and men sent from the front, sick and wounded, to Kharbin, Stretensk, Khavarosvsk, and other places in the rear of the seat of war, from the beginning of operations up to Jan. 14th (Jan. 1st, O.S.). The report relates to those officers and men who came under the attention of his staff in the hospitals over which he had direct control and does not include the losses at Port Arthur. Accurate particulars of the numbers killed in action are not available. The wounded officers were 1710 and the sick 2308, the wounded men 53,890, and the sick 72,531, making a grand total of 130,439. Of these, 107 officers and 3900 men died in the hospitals; a total of 17,722 were permanently invalided and 9429 were sent to European Russia to recuperate. At the date of the return there remained 21,554 in the hospitals.

Correspondence.

"Audi alteram partem."

THE CAUSATION OF LEPROSY.

To the Editors of THE LANCET.

SIRS,—The last number of the *Scottish Medical and Surgical Journal* contains a paper from the pen of Dr. Armauer Hansen of the utmost interest in reference to the causation of leprosy. Excepting by the few who love controversy for its own sake it will be read with much satisfaction by all, for it brings the rival camps of contagionists and non-contagionists as nearly as possible into union. It was Dr. Hansen's discovery of the lepra bacillus which gave new life to contagionist doctrines and it has been under his supposed leadership that measures for "the stamping out of leprosy" by compulsory segregation have been carried out in various countries. Prior to his renowned discovery Norwegian authorities (Danielssen and Boeck) were strenuous in their denial of contagion. That discovery, however, brought a change and made an epoch. Another step is, however, now to be taken. With that noble candour which is so marked a feature in his character the discoverer himself now admits that for practical purposes he has fallen back on the older creed. Speaking of the circumstance that in Norway lepers are allowed to travel, without precautions, in public vehicles Dr. Hansen states: "We have no particular rules for the transport of patients, *I see no reason for them.*" He goes on to add: "Leprosy is a disease which it is not necessary to have any particular dread of"—*that is*, not as regards its contagiousness—and he finally makes full admission that there must be some other and more important agency at work. "In order to stimulate it [the bacillus] into activity there are evidently required special circumstances—circumstances which we unfortunately know nothing of."

These pregnant expressions appear to admit quite fully that in the spread of leprosy contagion (in the sense of communication by touch, breath, clothes, &c.) plays only so small a part that it may be safely neglected and to assert that there is some other more efficient factor. Now those who advocate the food (or, more definitely, fish) hypothesis by no means ignore the bacillus. On the contrary, they assert that if only the living bacillus be received into the stomach it is efficient *per se* to the production of leprosy. The facts as to the disease in young children make this very probable. In this matter we are on the same platform with Dr. Hansen, if not, indeed, even more advanced in his direction than himself, since we are prepared to ignore all other "circumstances" if only the bacillus be received in the way mentioned. We have joined his camp in this belief, whilst he has now joined ours in denying the importance of precautions against other modes of contagion.

The question which remains open for debate between us is as to the nature of the "special circumstances" which are as a rule required in order "to stimulate the bacillus into action." He thinks that we know nothing of them. Some of us, on the other hand, hold that facts collected all over the world, and nowhere with more obvious pointing than in Norway, clearly indicate their nature. It is not, however, my intention on the present occasion to discuss that question. My object in asking you to publish this letter is simply to draw attention to the fact that our foremost authority on leprosy now definitely refuses to recognise the importance of precautions against contagion. Surely those who are responsible for the miseries of Molokai and Robben Island may suitably lay to heart Dr. Hansen's declaration that "leprosy is a disease which it is not necessary to have any particular dread of." I am, Sirs, yours faithfully,

March 2nd, 1905. JONATHAN HUTCHINSON.

THE INCIPIENT STAGE OF INSANITY.

To the Editors of THE LANCET.

SIRS,—Your annotation under the above heading in THE LANCET of Feb. 25th, dealing with a pamphlet by Mr. Charles Williams of Liverpool, quotes the latter as saying that his view, that from hallucinations alone a person should never be pronounced insane, is opposed to that generally held by the profession. According, therefore, to Mr. Williams the profession in general holds that from hallucinations alone a person should or could sometimes be pronounced insane. I entirely decline to believe that medical men, even excluding those specially engaged in the department of mental disorders (whom, however, he does not exclude), are so ignorant of the elements of psychology as such a view would imply, or so inferior to Mr. Williams in this elementary knowledge. Your annotation clearly conveyed to me that there was no reason to suppose that the general view in this matter differed at all from Mr. Williams's and that there was no likelihood of a diagnosis of insanity being made on hallucinations alone.

I understand him to say in the last paragraph of his letter that all the books on insanity he has read and all the superintendents of asylums he has spoken to teach and hold that persons suffering from hallucinations alone (for, of course, it is a question of these *alone*) are usually not insane. That is, they are sometimes insane. Will Mr. Williams mention the books which teach that hallucinations alone can constitute insanity and name the asylums where superintendents are prepared to receive and to detain persons suffering from hallucinations alone?—I am, Sirs, yours faithfully,

EDWIN GOODALL.

Joint Counties Asylum, Carmarthen, March 6th, 1905.

*** Mr. Williams did not represent our annotation correctly. We made no "complaint that persons suffering from hallucinations are not usually considered insane."—ED. L.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

To the Editors of THE LANCET.

SIRS,—As president of the Medico-Psychological Association and in that capacity chairman of the meeting held on Feb. 23rd at the North Riding Asylum I write to correct the report of proceedings published in your issue of March 4th on page 585 as it is inaccurate in a very important particular.

The Medico-Psychological Association at its last annual meeting decided that the period of training for nurses and attendants, before examination for the purpose of obtaining the certificate of competency in mental nursing, should be extended from two to three years, so as to bring the period of training in asylums into line with that in general hospitals. The resolution, which was moved by Dr. J. Carlyle Johnstone and seconded by Dr. E. B. Whitcombe, was not framed for the purpose of disturbing this principle but with the object of insuring that the entire period of training must be served in one institution. The amendment, which Dr. T. Outterson Wood proposed, contained no reference whatever to limiting the period of training to two years as is represented in your report and it may be said that there is no more ardent supporter in the association of the recent lengthening of the period of training than Dr. Outterson Wood. His amendment was framed with the purpose of allowing that the period of training already fixed at three years should be spent in not more than two institutions. This was adopted by the association. The error in your report which I have referred to so entirely misrepresents the action of the association that I venture to ask you to publish this comment.

I am, Sirs, yours faithfully,

Queen Anne-street, W., March 7th, 1905. R. PERCY SMITH.

*** The reporter who supplied us with the account of the quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland, referred to above by Dr. Percy Smith, endorsed his copy with a note to the effect that he sent the report "authorised by the secretary of the Medico-Psychological Association and at his request."—ED. L.

PROPOSED AMALGAMATION OF THE MEDICAL SOCIETIES IN LONDON.

To the Editors of THE LANCET.

SIRS,—I feel sure the majority of the members of the medical profession in London hail with satisfaction the proposed amalgamation of the medical societies. For some years I have thought what is required is the establishment of an Academy of Medicine in London, for which I trust the [illegible] In this academy the various [illegible] sections dealing with the [illegible] surgery, and obstetrics. The members of the societies would become *ipso facto* members of the Academy of Medicine, but the Fellowship of the academy should be conferred as a mark of distinction on those members who were in the opinion of the executive worthy of that honour. Further, by amalgamating the funds of the different societies it might be possible to acquire additional property in Hanover- [illegible] other accommodation. [illegible] this proposal would be [illegible] who might with dignity acquiesce in such a change whilst objecting to be incorporated in another "society" as has been suggested. I hope, however, an opportunity may arise for discussing this proposal at the meeting of the representatives of the different societies.—I am, Sirs, yours faithfully,

FREDERICK J. MCCANN, M.D. Edin., F.R.C.S. Eng.,
M.R.C.P. Lond.

Curzon street, Mayfair, W., March 6th, 1905.

TREATMENT OF PERFORATED GASTRIC AND DUODENAL ULCERS.

To the Editors of THE LANCET.

SIRS,—May I say a few words in answer to Mr. W. Bruce Clarke's letter in THE LANCET of March 4th, p. 600? The eight successful cases of perforated gastric ulcers published in THE LANCET last July were operated on 4, 5½, 10, 12, 17, 24, 24, and 48 hours after perforation. The only unsuccessful case had come about 100 miles by rail and was not seen until the third day after perforation when she was practically moribund. All the cases were treated by irrigation and suprapubic incision except one case of leaking subphrenic abscess. The fluid in the pelvis is noted as "foul" in three of the cases, "turbid" in two, and "gastric" in three. I still believe that irrigation combined with suprapubic drainage is the best way of cleansing the pelvic peritoneum and seeing that nine out of 11 cases of gastric or duodenal perforation treated in this way at St. George's Hospital have recovered I cannot allow that it is either "unnecessary" or "harmful."

I am, Sirs, yours faithfully,

G. R. TURNER.

Half Moon street, Piccadilly, March 6th, 1905.

SCHOOL GREEK IN SOME OF ITS NATIONAL ASPECTS AND THE *VIA MEDIA*.

To the Editors of THE LANCET.

SIRS,—Dr. William Ewart in his letter which appeared in [illegible] no less than her elder sister has decided upon the retention of Greek, so that for the present, at any rate, the matter is settled. It is probable that if Greek were given up it would not be long before the advocates of modernity would turn their attention to Latin on the plea that this is also a dead language. Latin, no less than Greek, is wont to be forgotten as years go by and it may be of interest to your readers if I quote a conversation which I overheard at a concert at Queen's Hall on Sunday afternoon. Sitting behind me were a man and a woman, the latter frankly ignorant and anxious to learn, the former no less ignorant but unaware of his ignorance. The woman remarked, "I wonder no corresponding word for 'going in' has been invented on the lines of 'exit.' I should think 'insit' might do." Whereupon the man replied, "My dear, if you knew Latin you would not say such silly things. 'Exit' means, he goes out. Exsum, exes, exit." Probably this man had had the usual school education, but because he made such an egregious blunder is it any reason that a student of science who has daily to use words derived from Latin or Greek should be deprived of the training which with a little application would enable him to use them aright? I am, Sirs, yours faithfully,

March 6th, 1905. M.A., M.D. OXON.

THE EPIDEMIC OF TYPHOID FEVER AT LINCOLN.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Continued from p. 604.)

Lincoln, March 6th.

THERE can be no doubt as to the prevalence of a wholesome feeling of discontent throughout Lincoln. This may be productive of great good if its strength is not divided and diverted into different directions by party politics. The feeling that the town has been misgoverned is widespread and this again would be very fruitful if the electors could bring themselves to realise that this is as much their own fault as the fault of those whom they elected. For instance, the most general complaint is that no timely warning was given and the people were only called upon to boil their water when it was much too late and several hundred persons had entered upon the period of incubation. This is true as a matter of fact but as a matter of policy there is another point of view. So late as the year 1903 as many as 32 cases of typhoid fever were notified and yet no epidemic ensued. On the contrary, during the following year up to the month of October only six cases were notified. Then there occurred the one solitary case on Dec. 2nd. It happened, however, that from Dec. 22nd. to 31st there were ten more cases; still, and even then, there were only 17 cases in all for the entire year and this is but a small figure. The suspicious feature about it is the fact that the last ten cases came close one upon the other. With the month of January matters became still more threatening; nevertheless, up to Jan. 23rd there were only 18 more cases. The town council was not absolutely asleep or indifferent. On Jan. 2nd it had sent samples of the water to the Clinical Research Association in London for examination. The reply was not received till Jan. 18th and it is now said that the corporation should not have waited but should have warned the people at once. Of course, all sanitarians would agree with such a principle and urge that the moment there is suspicion of danger and without waiting for analyses and lengthy bacteriological examinations, clear, emphatic warnings should be issued and full precautions should be taken. Therefore when the authorities felt sufficiently alarmed to send samples of water to be analysed—that is to say, on Jan. 2nd last—they should have issued warnings. As it is, they waited till they knew the result of the analyses—that is, till Jan. 18th, and then on the next day issued 13,000 handbills warning the population.

Supposing, however, that warnings were published from the very first, what would have been the position of the corporation if no epidemic had ensued? Undoubtedly the outcry and the dissatisfaction resulting would have been loud and keen. The corporation would have been denounced as mischievous alarmists who had driven the visitors and the trade from the city. But the most peculiar part about the matter is that the more successful the efforts of the corporation the more certain and the more virulent would be the abuse that they would call down upon themselves. Thus, if it is possible—and this is very doubtful—to issue warnings in such good time as completely to prevent any cases of typhoid fever occurring, then assuredly the corporation would be violently blamed for raising a false alarm. It is only in the event of the warnings coming too late to prevent the mischief that the corporation could hope to escape blame for creating unnecessary alarm. This obvious but disconcerting fact clearly shows that the authorities are placed in a false position and exposed to a cross-fire of criticism from which there is no escape. The cause is the conflict of interests. If the protection of public health was the only duty and object of the corporation the matter would be simple. But, as a rule, and when there is no startling epidemic to alarm the population, the elector thinks a great deal more about saving the rates and promoting trade than he does about the problems of water-supply, drainage, disposal of refuse, prevention of jerry-building, and kindred sanitary questions. It is for the purpose of saving the rates and avoiding any sort of action that may alarm and drive away trade that corporations blunder into epidemics. The people only perceive when it is too late that in the long run they have lost more than the cost of taking proper measures in good time. Will this lesson be effective at Lincoln? Will the inhabitants insist that before the interests of local trade and the reduction of taxation stands the question of public health; that the preservation of public health, however expensive at first, is in reality the truest of all economies.

In thus seeking to preserve the public health what will have to be done besides securing a pure water-supply? Looking at the distribution of the cases over the town and noting which are the streets and districts principally affected, there is some reason to believe that it will be necessary to take in hand the question of sewer-ventilation. Lincoln for the most part drains into small pipe sewers. These were laid down on the understanding that the separate system would be adopted. As a matter of fact, however, the sewers not only receive the sewage proper from the soil-pipes of the houses and the slops from the kitchen sinks but a very large amount of rain water from the backyards, the back portion of the roofs of the houses, and also used water from tan-yards and other industries. Thus there is more sewage in bulk than was intended in the first instance and, in consequence of the various industries, it is a more concentrated sewage than would have been the case had it been limited to domestic drainage. It is only the rain water that falls on the fronts of the houses and in the streets that does not penetrate into the sewers but flows along gutters and surface drains to the nearest water course. As already mentioned, there is no natural outfall for the sewers. By gravitation, and in some places the fall of the sewers is very slight, the sewage reaches a pumping station situated close to the city. Here there is a receiving tank and as the main sewer approaches the pumping station it is enlarged so as to form a sort of reservoir, where the sewage can accumulate till the pump is able to lift it and to send it on to the sewage farm which is further away from the city. But it is not a very large amount of sewage that can accumulate at the pumping station and its immediate vicinity. There is not space, for instance, for 100,000 gallons and when that amount or more is waiting to be lifted on to the sewage farm then it must flow backwards towards the town. In a word, the sewers become waterlogged. Consequently, the question arises whether any extra pressure of this description, affecting the internal condition of the sewers and driving an extra amount of sewer air out into the town, occurred before the outbreak of the present epidemic. As every gallon of sewage has to be lifted by a steam pump and every stroke of the pump raises the same volume of water the actual amount lifted is known most accurately. For the year ending March 2nd, 1902, the average amount of sewage lifted per week was 8,983,942 gallons. For the year ending March 31st, 1903, the weekly average was 8,799,693 gallons; but for the year ending March 31st, 1904, the weekly average was 10,706,731 gallons. This is a daily increase of nearly 300,000 gallons. Much more air, therefore, must have been forced back into the city and yet we are told in the city surveyor's report for that year that in various parts of Lincoln there were 218 ventilating pipes in connexion with the main sewers attached to private property, and that of this number one had been erected during the course of the year. While, as compared with the previous year about 90,000 000 more gallons of sewage filled the sewers and forced the sewer air out there was only one single addition made to that form of ventilating which consists of pipes running up the sides of private houses Judging from such figures it does not seem as if increased facility for ventilation had been provided to meet the increased necessity for such ventilation

When an epidemic is in progress the local officials are so overwhelmed with work that it is difficult to obtain minute information In spite of this however everyone was most anxious to help my investigations and I have to express my gratitude to the medical officer of health the assistant medical officer of health the city surveyor and the clerks in the corporation offices for their courtesy and patience though I persisted for hours together in studying their maps and figures Still, I felt that while the officials were busy in providing for the urgent needs of patients actually suffering I could not be too sparing in the questions put to them considering the amount of time that would be absorbed by answering these questions Thus for instance I have not obtained complete statistics as to the amount of sewage in the sewers during the whole time of the epidemic Still, I did ascertain that during the week ending Nov 13th last the *engine at the pumping station* had to lift out of the sewers and to send on to the sewage farm 8 200 000 gallons of sewage The next week ending Nov 20th there were 9 600 000 gallons I do not give the odd figures On Nov 27th there was a further increase to 10 500 000 gallons On Dec 4th the amount was above the average—namely 10 770 000 gallons while for the two following weeks those ending on Dec 11th and 18th there was a much greater increase—namely 11 430 000 gallons and 12 900 000 gallons Indeed, it is admitted that there was an increase over the normal quantity of sewage equal to about 25 per cent for a few weeks preceding the epidemic If therefore by forcing out of the sewers a larger amount of air than usual a greater predisposition to typhoid fever is created the statistics derived from the pumping station at Lincoln are quite in keeping with such a theory There was extra pressure for some weeks before the commencement of the epidemic During that time the sewers were water logged to a larger extent than usual Of course it must be borne in mind that the difficulty rests not so much in regard to the volume of sewage but in the fact that the greater part of it comes in the morning and the amount of work done in pumping is not evenly distributed over the whole day If this were so taking the last and highest annual figures given they amount to a daily average of 1 529 533 gallons and this is only 64 000 for each of the 24 hours The pump can easily lift 100 000 gallons in an hour But that is not the way sewage comes Even when it is not influenced by rain the greater part flows at special times and not all the time, and this it is that causes the accumulations in the sewers

There is not only the general question of forcing air out of the sewers by the accumulation of water in the sewers but it is necessary to study with even greater care the places where that air escapes and the connexion such escape may have with the actual cases of disease If it can be shown that those localities where the greatest quantity of air escapes from the sewers have suffered more than those localities not so affected the case will be much stronger It is possible however, to go even further than this and to compare not only locality with locality street with street but house with house

Such an investigation would take much time and require a very intimate knowledge of minute details Nevertheles and though as yet much still remains to be seen and examined the results already attained are certainly interesting and suggestive Perhaps the most characteristic district is that already mentioned which though inhabited by the lowest and poorest class has been remarkably free from typhoid fever This district is bounded on the south by the river Witham, on the east by the railway to Grimsby and Hull and I would take Montague street for its western limit Within these limitations is comprised about a third of the river embankment known as Waterside North Here the main collector passes and there have been ten cases of fever but it is not easy to ascertain how many of these occurred in the smaller portion of the embankment that forms the southern boundary of the district now described Then Croft street and its continuation known as Winn street, may be taken for its northern boundary and these streets run of course, from east to west Towards the eastern end of this district there is a syphon which passes under the river Witham and conveys the sewage of the northern half of the town to the pumping station which is but a short distance on the other side of the river The district in question is the

'tion

nore

the

ged

The ordnance map gives the level of the lowest part of the water side embankment at 15 feet , this is at its eastern extremity It then rises to 16 feet and attains 18 feet at Montague street which is the western extremity Going to the northern line where Croft street traverses Montague

stree the level falls to

20 9 then this street

ascer ther eastwards

In a n is from five to

seven or eight feet so that it is comparatively flat Here is the district which has not suffered much from typhoid fever Being nearest to the river it was inhabited early and the older property has degenerated and is now tenanted by the poorest classes Immediately north another district of

about the same size is

better class of inhabi

former district would c

second district the east and west would be likewise bounded by the railway and by Montague street and the northern demarcation line would be Monks road Here at the top of Montague street the level is 58 feet—a rise from Croft street of 31 feet At the top of Baggolme road the level is 49 feet and just below where Croft street merges into Winn street the level is 20 7 feet Further eastwards the rise is from 22 to 45 feet Therefore the rise in this district varies from 23 to 31 feet Indeed this is the beginning of the hill that leads up to the cathedral

The record of the cases of typhoid fever is not as yet absolutely accurate in regard to their topographical disposition Though some omissions may have been made and *some corrections* will be necessary the general bearing of the facts will remain about the same For the lower district described above there are recorded 30 cases, but of these ten cases occurred in Cannon street and seven in Winn street others in Lord street and Eastfield street, in fact a good two thirds of the cases are located in the upper half of the lower district Then going over to the higher and better class district I found 39 cases Thus where the houses are not more than five feet above the river level there seem to have been only about ten cases in which I include four out of the ten cases occurring on the lengthy embankment called Waterside North On the other hand in the houses standing on ground that is from six feet to 40 feet above the waterside level there were some 50 cases and the higher above and the further from the river the better *the class of property* These better class houses are inhabited by the more prosperous section of the artisan class and by members of the small trading class Whereas the property near the water is inhabited by hawkers beggars, and tramps yet it is these who have suffered least though they all drink the same water

To explain this difference this unexpected susceptibility of those who enjoy what at first sight appears to be better sanitary conditions it would be necessary to trace the course followed by the sewer gases as they are forced out of the water logged sewers The pressure being from below and the air being warmed in winter because the sewer is warmer than the street the tendency of the sewer air would be to travel upwards The ventilating pipes and the manholes in the streets on the lowest levels cannot act as ventilators when the sewer is water logged There is no open space for them to ventilate since the sewer below them is full Ventilation is then only possible at the higher levels and the question to be solved is whether the houses where the greater number of cases have occurred received more than what might be described as their fair share of deleterious atmosphere pumped out upon them from the sewers What I have seen certainly helps to bear out this suggestion In Winn street I visited three houses standing side by side There had been no case in the middle house and here at the back a pipe sewer ventilator went up to the roof The north and

before the epidemic

of this ventilator

ouse where there

had been a case of typhoid fever While this may be noted at the back of the house it should be observed that there is also a manhole over the sewer just in front of the house. In the third house there had been two cases of typhoid fever and two cases of scarlet fever. At the back there was another sewer ventilating pipe, but what was particularly significant is the fact that this pipe had been broken off at the top. Instead of being carried upon and above the roof of the house the pipe abutted immediately under the ledge of the roof. The air coming out of this pipe would therefore strike the ledge of the roof and would be deflected downwards. Following the wall the sewer air would reach the upper portion of the two windows of the two bedrooms situated on each side of the pipe. The mouth of the pipe was not more than two feet or so from these windows and it was precisely those persons who slept in the two rooms thus exposed to the invasion of sewer air who fell ill with typhoid fever and with scarlet fever.

In the Monks-road I found another equally significant combination of circumstances. Here in a very pleasant looking villa close to the park and well situated on the wide road there have been two cases. The first was that of a young lady whose bedroom window overlooked the road manhole. Such bad odours escaped from this manhole that the inhabitants of the house often poured down bucketfuls of disinfectants in the hope of reducing the nuisance. The lady's brother was the second to fall ill from typhoid fever. His bedroom window was round the corner of the villa overlooking the side street. Immediately by his window a sewer ventilating pipe goes up to the roof of the house. No odour, I was told, had been noticed coming down from the roof but there is a joint in the pipe about five feet above the ground. There was no lead or cement in this joint and the two pieces of the cast-iron ventilating pipe fitted so badly that the sewer air came out freely. The odour could easily be detected. It blew into the side door which was close by and thence into the pantry where the food is kept, or else it ascended up to the window of the room immediately above. It was in this room that the brother who contracted the fever was in the habit of sleeping. Several other houses where there had been cases of typhoid fever were also especially subject to receive air escaping from the sewer but of course there has not been time yet to go into this matter thoroughly. Still, and though these incidental cases must not be taken as conclusive, they do suggest a possible connexion between the escape of sewer air and the greater prevalence of fever in certain districts, streets, and houses. If that can be more conclusively demonstrated than is possible in this preliminary examination of local conditions then we have yet another proof that the ventilation of sewers is, generally speaking, a question that has not been satisfactorily solved. At Lincoln as much attention has been devoted to this matter as in most other towns and yet the present state of affairs seems fraught with no inconsiderable danger.

TUBERCULOSIS IN FRANCE.

(FROM A SPECIAL CORRESPONDENT.)

L'Œuvre des Enfants Tuberculeux.

IN view of the International Congress against Tuberculosis to be held in Paris next October English readers may be interested to become acquainted in advance with L'Œuvre des Enfants Tuberculeux. This popular society, having for its object the free treatment under ideal conditions of tuberculous children, was founded under its modest title in 1888, when a country residence at Ormesson, 26 kilometres outside Paris, was given for the purpose and was opened to receive 12 patients. In 1894 it received the well-recognised distinction of being officially declared to be of public utility. The moving spirit of the movement has been Dr. Léon-Petit, its secretary-general; but its list of supporters, members of committee, and past presidents include Dr. Brouardel, senior French representative at the London Congress; Dr. Hérard, President-elect of the coming Congress in Paris; Dr. Hutinel, professor of pathology; Dr. Blache, its late president, and Dr. Grancher from the medical profession; M. Jules Simon, M. Georges Picot, M. Casimir Périer, and M. Emile Loubet from the world of literature and politics, and a considerable number of well-known names belonging to the old French aristocracy. At the annual meeting held on Feb. 9th the Agricultural Hall of Paris was packed full of the society's supporters, most by appearance of the *bourgeoisie*, who stood for hours in the doorways and stairways listening to the speeches, which lasted two hours, before they could be rewarded with a first-rate programme of music and recitation provided by popular actresses and platform musicians. To English minds, accustomed to Mansion House meetings and charitable funds on a vast scale, a national work spending under £8000 in the year on 400 tuberculous children would hardly seem likely to present any very thrilling interest. But organised philanthropy is still in its infancy in France and in philanthropy, as in everything else, the Frenchman makes the most of what he is spending and the meeting was an enthusiastic success. The visit to the hospitals here described was kindly arranged in special honour of the visitor who was received a couple of days later at the station of Villiers-sur-Marne by Dr. Vaquier, the physician in charge, who is also allowed to engage in private practice. Villiers is 21 kilometres out of Paris from the Gare de l'Est, and standing high it commands a fine distant view of the city, embedded away to the west towards late afternoon in the golden haze of a wintry sunset. The three hospitals of this society all lie within a few miles of each other to the E.S.E. of Paris. The most recent, that at Noisy-le-Grand, which is passed in the train, was opened only two years ago for girls of from three to 10 years of age. The first at Ormesson has about 100 beds for small boys from three to ten, while that at Villiers has nearer 200 for boys from 10 to 16 years of age. All alike are managed by religious sisters of Sainte-Anne, women devoted to the work although devoid of any previous systematic professional training, but the older boys at Villiers are managed as regards discipline and education by men of similar standing to board school masters.

The small boys' hospital, or sanatorium as we should call it, at Ormesson is centred round a country house given for the purpose in 1888. This is now used by the seven or eight sisters who control the whole management and do most of the menial work themselves. On one side there has been added a fine, lofty, and spacious dining hall, with kitchens at the end and long windows down either side. A hundred little boys were standing in blue smocks beside two long tables and as the sister gave the command by a wooden clapper they recited a grace, crossed themselves, and sat down to their afternoon milk. Children of any creed or race are received without distinction; but as there is a bright little Roman Catholic chapel and the discipline is in the hands of *réligieuses* it is probable that all have to conform for the time to Roman Catholic practice. The dining hall looked bright, clean, and airy but there is a great objection to the French windows, which open down their whole length or not at all, insomuch that during most of the year the children sit with closed windows. Hot air is certainly admitted freely but its freshness is always open to suspicion, even if it does drive out the stale air through the outlets designed for the purpose in the roof. This appears to be a radical defect in house construction throughout France and above all in houses intended for the treatment of pulmonary tuberculosis. From the central building are also built out at either side two long, spacious dormitories, floored in wooden parquet and equipped with nothing but simply furnished beds and a few chairs; while at the end are the lavatories, baths, and water-closets without wooden seats; small sleeping rooms for the sisters in charge; a room at each end for isolation of infectious cases, for instance, of measles or scarlet fever, which have hitherto been here successfully isolated; and along the southern face of each dormitory runs an open, flagged verandah. Finally, this southern face is completed by a fine, lofty hall, built up against the original house; floored in linoleum, with tiled and painted walls and rounded corners, equipped with low benches and a few long chairs for invalids, and used as a playroom in all weathers. The grounds to an English eye are dull and uninteresting, with long stretches of rough gravel and no signs of swings or games. At the entrance is a pavilion in which relatives and friends are received and where they can see the children.

The big boys' hospital at Villiers is now a considerably larger affair. Based on a house belonging to M. Bonjean who took in ten waifs in 1891, it was enlarged by a couple of wings to take in 40 tuberculous children in 1892. In 1893 £5000 from the Pari-Mutuel enabled the society to build a hospital ward and gallery and by an extensive popular subscription, entitled "Les Enfants de France," a new pavilion of large dimensions was inaugurated by M. Faure in 1896

and dedicated to the memory of Villemin the military surgeon who described
who is celebrated by
as also by a good statue
the chief donors amongst the 12 000 subscribers are set out in detail on the wall of the staircase Finally, there have just been completed the workshops for making clothes and boots and the long covered playroom on one flank of the building and on the other the workrooms, laundry, and machine house in which a gas engine runs a dynamo and pumps water for the establishment Owing to the workshops the staff of sisters here numbers 25

The Pavillon des Enfants de France is certainly of a remarkably original and interesting design It is built in two floors—ground floor and gallery—round a large, open central space The gallery is of light iron and wood construction and the whole impression is like that of a museum, the place of the cases being taken by very frigid looking beds or in the central slightly sunken well by a few stiff chairs and tables The building measures some 120 feet by 70 feet and is nearly 60 feet high, with a half glazed roof and English sash windows all the way round on both floors The beds were ranged mathematically round the gallery and round the outer region under the gallery on the ground floor At the corners were windowed cubicles for the *surveillants* On both floors were doors opening into lavatories bathrooms (three baths to each floor), and dressing rooms This pavilion is used as a sleeping room only at night Patients confined to bed are retained in the olde
ke an ordinary hospital ward,
side where they can be quiete
ne of the sisters Round the house is a good garden on which some care has been expended to asphalt the paths and to keep down the dust in summer It is difficult to say, at least without spending some time as an inmate if any advantage is gained by a large, open pavilion such as this at Villiers Given English windows and the recognised English demand for fresh air, it is probable that tuberculosis may be as well treated in a bedroom or ordinary ward as in any of special size or design The French public however even more than the English, have a rooted aversion to cold air, preferring hot and stale at all costs If the windows then are of French design or if being on the sash principle they are kept closed throughout the night there is some real excuse for the eccentric design of the Pavillon des Infants de France As to artistic merits, the worker in English hospitals is completely spoiled for any appreciation of French wards The religious sister, the *surveillant* the *infirmier*, all alike seem to work by hard and unbending rule of thumb The discipline appeared rigid, there were no signs of spontaneous gaiety amongst the children who appeared to be essentially at school, in no ward apparently was there a piano or picture or note of decoration and there were no cushions or ribbons, no flowers and no toys If the womanly touches familiar to our English wards despite the alleged professionalism of our nurses be thus absent surely there must be a corresponding lack of that sympathy which at all ages is a strong power for good and in childhood is one of the most important factors in any treatment

The general stay of a child in hospital is from two to six months Many stay for longer some for years, but it is best to send them back if possible within half a year for after that length of absence the parents become unwilling to take them home at all The numbers treated were in 1903 for instance, at Ormesson 167, Villiers 149 and Noisy le Grand 79 total 395 Their average stay in hospital was 71 days, and the general result of several years past has been a mortality of 10 per cent and an apparent recovery rate of from 25 to 27 per cent Cases are admitted by recommendation of the family medical adviser declaring the existence of pulmonary tuberculosis, corroborated by examination at the hands of a medical admission committee and by a domiciliary visit paid by female inspectors The year's expenses include £800 invested, £2000 for central stores drugs and shops, £1300 for dispensary and offices in Paris, £900 for Ormesson, £2000 for Villiers, £1100 for Noisy, and £250 for a now extinct sanitary colony at Trénilly, total, £8600 The upkeep of a bed is quoted at £20 a year Any subscriptions from 8s a year upwards qualify for membership of the society of varying grade

Le Dispensaire Antituberculeux Emile Roux de Lille

An English visitor to Paris may well stop on his way through Lille and see M Calmette's antituberculous dispensary as a type of work which has a future before it of the very first importance There is a Fédération des Œuvres Antituberculeuses Françaises the monthly organ of which, entitled *La Lutte Antituberculeuse*, gives from time to time most excellent accounts of the theory and practice of these dispensaries but a few brief notes may not be out of place in the pages of THE LANCET to follow the account given of sanatoriums on the ordinary plan at Bligny, Ormesson and de Villiers The principle may be briefly stated Tubercle kills 150 000 Frenchmen every year, a population equal to that of Rouen or Nantes, the friendly societies spend £160 000 a year on 75 000 cases of tubercle £8 000 000 would be required to build and £3 000 000 yearly to maintain the sanatoriums required for their treatment And the treatment is long, doubtful, and unacceptable to most working people Without in any way underestimating the value of sanatorium treatment as the ideal, especially for curable cases, the present movement has as its object to initiate dispensaries in the towns as the indispensable adjunct of the sanatoriums Its essential aim is not that of charity, to supply medical advice and to distribute drugs or doles
to save to the State as m
as possible The dispe
school for adults It seeks therefore, to find out all cases of poor consumptives, to attract them and to keep control of them to understand their local conditions to advise them either to apply for sanatorium or other hospital treatment for themselves or at least to take steps to prevent the spread of infection, and for these ends to give them material assistance in the unequal struggle with disease in which they find themselves placed through no fault of their own Lille is chosen as a sample of a great industrial city in which, out of a population of 220 000 persons there are 6000 poor consumptives of whom from 1000 to 1200 die every year

The precise method employed at the dispensary is as follows A new case is received from 4 to 6 on any week day evening and from 9 to 11 any Sunday morning, and is given a card for consultation on a particular day at a particular time so as to avoid his being kept waiting, together with a pocket spittoon in which he is to bring a specimen of his sputum At the appointed time he is seen by the medical director or one of his three assistants, who makes a thorough physical examination and verbal investigation of the case and registers the details on his clinical history sheet
his family history, habits,
suspicion of tubercle the
r, tubercle is diagnosed or suspected he is given a carefully worded pamphlet (which is fully explained to him) of instructions as to the precautions to be taken and his own interest in the matter, he is supplied with pocket and table spittoons and a litre of lysol and is told when to come for a second visit The next step taken by the dispensary is the personal inquiry by a working man It is recognised that none but a working man can fully be received as his equal by a working man or can be expected to find out the exact conditions of his life or to enter fully into his difficulties in suggesting plans for its amendment A working man M Haenjens has therefore been engaged by the dispensary, himself formerly a woolcomber and secretary of a benefit society who speaks both Flemish and French and has been thoroughly trained in the principles of domestic sanitation and the fight against tubercle He now pays a visit to the home of the patient and is usually able, with a hearty

order book—30 litres of milk for the month a month's lodging or supplies of eggs meat, or coal Some are given warm douches every day, some are relieved of the care of their children who are billeted out on other families or sent to the sea sanatorium at Luydcoote near Dunkerque This

year it is hoped to send a few select and curable cases with their families to small, healthy houses, especially built for the purpose, out in the woodland and the country air.

The Emile Roux dispensary at Lille was founded in 1901 as the result of a public subscription, doubled by a vote of the municipality, which also provided an admirable site in the Boulevard Louis XIV., where it is now almost hidden between the imposing Pasteur Institute on the one side and the city walls on the other. It is essentially, as desired, in the poor and industrial quarter of the town. It is simply built—a one-floored building measuring 42 by 35 feet besides annexe—with ample accommodation for a large out-patient attendance, every attention being paid to the requirements of light, air, and cleanliness. Out of a good-sized waiting hall there opens on one side the office of the workman-inspector; on another side are a couple of medical consulting rooms with a dark room and a clinical laboratory for examination of sputa; on the third side are an office where all registers are kept and a passage leading to a glass-roofed hall where patients are accustomed to the use of a long chair and are taught breathing exercises. Beyond this is an annexe, including the douches, laundry, and drying rooms, and a room for the receipt, sterilisation, and distribution of milk. The total cost of building and equipment was £1440.

The information thus being collected is of considerable importance and interest. Of 592 patients examined in a year 261 were suspected of tubercle, 144 male and 117 female, 81 and 86 respectively being between the ages of 20 and 40 years. In the first three years during which the dispensary was open, 1901–03, 780 cases were diagnosed as tuberculous; most occurred in the months from February to July and least (5 per cent.) in the month of January. The first six decades of life contributed respectively 9, 129, 271, 238, 105, and 26 cases, five only being diagnosed in persons over 60 years of age. The majority belong to the textile or clothing industries; and come from the most crowded and least airy quarters of the city. Physical overwork, according to a recognised criterion, was found in 98·22 per cent., insufficient feeding in 71·26 per cent., alcoholism in 15·32 per cent., defective sanitation of workshops in 16·09 per cent., tuberculous parentage in 20·68 per cent., other tuberculous relationship in 19·54 per cent., and contagion only in 9·19 per cent., being two cases in public life and 22 in marriage. Most live in small rooms, in overcrowded rooms, or in rooms with only one window or skylight. Of the 152 invalids receiving material assistance on an average for six months in 1903, 51 increased in weight an average of eight pounds, 38 remained stationary, and 63 diminished an average of five and half pounds. For medical results, 17·76 per cent. are returned as improved, 25·65 as stationary, 19·73 as aggravated, and 36·84 as dead.

The cost of the establishment is comparatively slight. The medical service, including the director, costs £126; inquiries and sanitation of rooms, £84; cleaning and administration, £90; laundry, £64; spittoons, £13; with other general expenses amounting to a total of £550. The material assistance to 347 families in 1903 amounted to £966, including £360 for milk, £284 for eggs, £160 for meat, £80 each for coal and lodging, and £18 for sending children to the sanatorium. The total cost of the dispensary, therefore, for the year was 37,850 francs, or £1514, or roughly £10 for each invalid and his surroundings. It may be objected at first that the material assistance is in danger of pauperising the invalids, and this will undoubtedly be the case if proper care is not taken. But the essential object of this material help is to attract and to keep in touch with the adult pupils of this antituberculous school, and, consistent with the attainment of this object, it rests with the director and, above all, with the workman-inspector to see that the funds are used to good advantage. The essence of the system, in fact, is the workman-inspector, and considering how easy it is in England to find men of this class coming forward to pass the examinations of the Royal Sanitary Institute and to compete for the position of sanitary inspector there should be every hope of the system being adopted with good effect in some of our large English cities. Dr. A. Newsholme and others have decided that the great work of a sanatorium for tuberculosis is to train its inmates for their future life at home. This training needs to be confirmed, continued, supervised, extended, or supplemented by some such institution as the antituberculous dispensaries of France and Belgium, of which a most notable example is afforded by that under the guidance of Dr. Calmette at Lille.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University Intelligence.

Mr. Jordan Lloyd, professor of operative surgery, has been elected to represent the Faculty of Medicine upon the Council of the University, *vice* Professor H. G. Barling who as Dean of the Faculty is *ex officio* a member of the Council.—The Huxley lecture this year will be delivered on Thursday, March 23rd, by Professor E. B. Poulton, M.A., F.R.S., of the University of Oxford.

Mentally and Physically Defective Children.

The school accommodation for mentally and physically defective children was considered at the last meeting of the Birmingham education committee. Mrs. Hume Pinsent presented the report of the special schools subcommittee, from which I gather that there are about 1000 mentally defective children in the city, less than half of whom are receiving instruction in special classes. Excluding feeble-minded cripples, who are not eligible for any school in Birmingham, it is estimated that school accommodation should be provided for 600 feeble-minded children, whereas at present there is only accommodation for a little over 300. The scheme submitted by the subcommittee further included the provision of a boarding school in order to organise and to complete the work done for defectives. It was pointed out that the industrial homes for the feeble-minded which are about to be erected by the Poor-law guardians will be incomplete without some such boarding school. It was stated that the effect of adopting the scheme would be that an adequate education would be given to 1000 feeble-minded children at an annual cost of £10,000 instead of, at present, an inadequate education to 500 at an annual cost of £3400. In the discussion which followed most of the speakers were in favour of the scheme and the report was finally approved, with the exception, however, of that part relating to the boarding school.

Increase of Lunacy.

Councillor Davis, the chairman of the lunatic asylums committee of the city council, in a recent address gave some statistics which although they were selected arbitrarily may be taken as showing that there has been a 100 per cent. increase of patients suffering from lunacy during the last 40 years in Birmingham. He expressed the opinion that drink was accountable for a greater proportion of the cases of insanity in Birmingham than in England as a whole and that drink and hereditary influence were respectively accountable in Birmingham during the quinquennial period of 1898–1902 for 17·9 per cent. and 26·8 per cent. of the admissions. He considered that in view of the large proportion of cases due to the latter cause something should be done to prevent insane patients having children.

The Unemployed.

The conference to which I referred in my last letter as shortly to be held between representatives of the city council and the three local boards of guardians was well attended. The feeling of the meeting was favourable to the acceptance of Mr. Fels's offer to lend land for the formation of a labour colony and a subcommittee was appointed to consider the details of the scheme. One of the difficulties in the way, according to one of the speakers, was that if land could not be obtained in the neighbourhood of Birmingham the authorities would either have to send out the men by railway or to provide barracks for them. Professor Muirhead of the University contributed some notes upon the conference to the press. He thought that the continental labour colonies had been a failure and that before embarking on such expensive schemes we should give a more prolonged trial to labour registries, that children should be more frequently brought up with a knowledge of some trade, and that membership of the various workmen's societies should be more universal. He expressed himself as not altogether in favour of work relief in preference to relief in food or money, since those engaged in such work were often unsuited and during the time they were at work they were prevented from seeking employment in their own trades.

Housing in Birmingham.

Some years ago certain land at Bordesley Green was acquired under the Housing of the Working Classes Act for the purpose of erecting artisans' dwellings thereon. The scheme failed to receive the sanction of the council and it is now proposed to let out the land to private builders with the same object in view. It is said that several offers have been received and that shortly a recommendation will be made to the city council.—By the opening of Rowton House, Highgate Park, Birmingham is now possessed of a "workmen's hotel," which it is hoped will prove a boon to poor respectable single men. It is built after the style of the Rowton houses in London and sleeping accommodation is provided for 819 men. The company has a nominal capital of £50,000, all but £3000 of which has already been subscribed. The entire cost of accommodation for a day and a night is 6*d.*, and including the cost of his food it is estimated that a man may live comfortably for from 9*s.* to 11*s.* per week.

Medical Charities.

The Blackwell Sanatorium, which has been undergoing alterations and additions, will soon be completed. As a result of the change there will be 20 additional beds provided. It is all the more unfortunate that this improvement should be coincident with a falling off in the subscriptions. The Birmingham General Dispensary and the Children's Hospital also report a debit balance upon the work of the last year. So great has the out-patient work become at the latter institution that the medical staff has found it necessary to limit the number of new patients to be seen to 65 per day.

A Return of Small-pox; Health of the City.

A case of small-pox was reported on Feb. 24th and on the day following it was ascertained that two other cases existed. The outbreak has been confined to one common lodging house. The usual precautions to prevent the spread of the disease were promptly taken and the patients were removed to the hospital. Apart from small-pox the general death-rate for the two last weeks of February has been very satisfactory—viz., 15·5 and 14·3 per 1000. There has been during this period a slight increase in the number of cases of scarlet fever and diphtheria. The health committee has reported upon the general statistics for 1904. The birth-rate was a low one—viz., 31·5 per 1000, against an average of 32·6 in the previous ten years. The death-rate was 19·3 per 1000, as compared with 17·2 in 1903 and 18·0 in 1902. The higher mortality rate was due to a severe epidemic of whooping-cough of a virulent type and to epidemic diarrhœa resulting from the long, warm, dry summer.

March 7th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Town's Memorial to the late Sir William Mitchell Banks.

THREE months ago a public meeting[1] was held at the town hall, under the presidency of the Lord Mayor, to initiate a permanent memorial of the late Sir William Mitchell Banks. In response to the appeal made for funds to attain that object it is gratifying to record that the sum of £5523 has already been subscribed. It was agreed by the subcommittee appointed to consider the subject to found two memorials. A lectureship is to be attached to the University of Liverpool and to be called the "Mitchell Banks lectureship," to which a sum of £1500 is to be devoted. The University authorities will be enabled to invite yearly a distinguished surgeon, pathologist, or anatomist to treat of the latest investigations and discoveries in medical science. As Sir William Banks had a long and honourable association with the Royal Infirmary the committee decided to perpetuate his memory in connexion with that institution by raising a further sum of £5000 to be applied to the cost of the contemplated new out-patient department at the Royal Infirmary and associating his name with the gift. A sum of £967 has still to be raised to accomplish the committee's desire and there can be no doubt that the required amount will be forthcoming shortly, as the idea of the memorial is popular with all classes.

Low Death-rate in the City.

At the meeting of the health committee of the city council held on March 2nd Dr. E. W. Hope (the medical officer of health) alluded to the death-rate of the city for the past week, which stood at 16·4 per 1000, as the lowest on record. The decline of the death-rate appeared to be general in the city. The saving of life was most marked in respiratory diseases, tuberculosis, and zymotic diseases. It was gratifying, too, that the decline was so marked in every age-period, notwithstanding that the weather had been more severe than 12 months ago.

The King and the University of Liverpool: Gift to the Anatomical Museum.

His Majesty the King has very graciously acceded to a suggestion that the skeleton of Ambush II., the famous steeplechaser from the Royal Stables which died some weeks ago, should find a place in the Museum of Veterinary Anatomy at the University of Liverpool. His Majesty was approached on the subject by Mr. J. T. Share-Jones, veterinary anatomist to the University, who pointed out in his communication that steps were now being taken to establish an anatomical museum at the University and that it was the ambition of those at the head of the department to secure, as far as possible, objects of historical as well as anatomical interest. The skeleton will be mounted and placed in a prominent position at the University museum and a plate will be affixed giving a short history of the well-known horse. This is the first presentation that has been made to the museum but other specimens of historical interest will no doubt be received from time to time. The veterinary school was formed towards the end of last year as a necessary adjunct to the University in such a centre as Liverpool.

David Lewis Northern Hospital.

It was stated at the annual meeting of the subscribers to this charity that the debit balance now amounted to £7034. The ordinary expenditure was £10,432, while the total income was only £8457, including £1897 18*s.* from the Hospital Saturday and Sunday Fund. Efforts were made to increase the number of annual subscribers but with a very poor result. The financial condition of all the Liverpool hospitals is not at all promising.

The New Director of Cancer Research; Admission of Women Students at the Royal Infirmary.

Professor John E. Shorrock Moore, F.L.S., has been appointed director of cancer research in succession to Professor A. S. F. Grünbaum. As professor of natural history at the Royal College of Science, London, Professor Moore is well known as an investigator in cancer. He has also distinguished himself by his explorations in Central Africa. The committee of the Royal Infirmary has appointed him a member of the infirmary staff in accordance with the terms of the donation that the research work in cancer should be carried on at the Royal Infirmary. The committee of the Royal Infirmary has agreed to the principle of admitting female medical students to the practice of the hospital on the same conditions as apply to male students. By the terms of the charter of the University of Liverpool all degrees are open to women.

Infirmary Extension at Chester.

An interesting ceremony took place at Chester General Infirmary on Feb. 21st to mark the completion of extensive [illegible] the out-patient department. [illegible] the old dispensary and small [illegible] to a roomy, well-lighted waiting hall; the consulting rooms have been improved, a new dispensary has been built, and a casualty ward provided. A copper plate is to be affixed to the new building explaining [illegible] been effected at a cost of £500 [illegible] the late Mr. John Alexander [illegible] authorised by the terms of the [illegible] the benefit of such charitable institutions as they should select.

March 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Edinburgh Asylum for the Insane.

THE statutory annual meeting of the Royal Edinburgh Asylum for the Insane was held on Feb. 27th in the City Chambers, Edinburgh. The report of the ordinary managers stated that the daily average number of patients under treatment in new Craig House with the adjoining villas and at Myreside Cottage was 205 as against 207 during the preceding year. The average daily number of patients in the intermediate wards of the West House was 113 against 118 during the preceding year. On Dec. 31st, 1904, the total number of patients in Craig House and Myreside Cottage was 293 as compared with 295 in the previous year, while the intermediate patients numbered 104 as against 92. The private patients at the lowest rate of board numbered 53 as against 55, while the rate-paid patients numbered 464 as compared with 572 in the previous year. The total on Dec. 31st was 824 compared with 924 in the previous year. There had been a gross diminution in the average number of patients of 44, this being mainly due to the fact that the average number of rate-paid patients had declined by 41. In the course of the year 185 rate-paid patients had been transferred from Morningside Asylum to the District Asylum at Bangour. The ordinary income from all sources (exclusive of the sum of £676 8*s.* 7*d.* debited to Craig House and credited to the West House for labour performed by pauper patients) amounted to £56,807 16*s.* 4*d.* The ordinary expenditure amounted to £52,873 17*s.* 8*d.*, leaving a surplus of £3933 18*s.* 8*d.* After deducting the annual instalment towards liquidation of the debt on the West House the free surplus was £1880 6*s.* 8*d.* The free surplus was applied to the reduction of debt. The report of the charity committee was also read and showed that at the close of the year the fund of the committee amounted to £9787 13*s.* 5*d.* and that the ordinary income had been £350 9*s.* 8*d.*, while the ordinary expenditure had amounted to £425 17*s.* 9*d.* The number of patients relieved during the year had been 38 and the number on the roll at the close of the year was 34. The Bevan Trust Fund at the close of the year amounted to £12,830 14*s.* 4*d.* The ordinary income had been £463 10*s.* 6*d.* and the ordinary expenditure £369 5*s.* 5*d.* The number of patients relieved during the year had been 33 and the number on the roll at the close of the year was 25. The report of Dr. T. S. Clouston, the physician-superintendent, stated that in the beginning of the year the number of patients was 929 and on Dec. 31st there were 829 patients in the asylum. There were 457 admissions, 195 being men and 262 being women. The total number of patients under treatment was 1386. There were discharged 434—208 men and 226 women. There were 123 deaths—55 men and 68 women. The average number of patients resident was 872—429 men and 443 women. The report stated that the past year had been a record one in the number of admissions to the asylum. Only once before, in 1896, had there been more patients admitted within the year. The rate-paid admissions amounted to 347, or 13 less than the average of the past five years. There had been 36 more admissions of the private class than the average of the past five years. It had been many years since it was possible to admit this class so freely and it was now possible owing to the removal of 185 rate-paid patients to the new Bangour Asylum in summer which had been an enormous relief to the wards. As the accommodation provided at Bangour consisted so far of only two large wards with no single rooms and no special hospital, none but suitable cases could be sent there, leaving at Morningside a disproportionate number of the weak, the noisy, the suicidal, the epileptic, and the paralysed. On that account it had not been possible to make any reduction in the staff and the average expense of treatment went up. 12 voluntary patients had come for treatment. The proportion of recoveries in this class was much higher than among the certified. It was necessary and important that early and threatened cases of mental disease should be treated properly. There was in the Scottish Acts a vague provision for the treatment of any patient for six months with a view to cure if a medical man wrote a certificate to that effect. By means of this little known and seldom acted on provision public hospitals and parish or county councils might set up psychiatric wards or hospitals and so render what the Glasgow parish council had done strictly legal. This country was distinctly behind Germany, Denmark, and the United States in this matter. Mental disease ought now to be looked on as one of the results of breaking natural law. Men and women did not yet realise their health risks or their health duty. To see an Education Bill that made no direct provision for teaching health and an educational system which neglected the formation of self-control and character as its highest duty was the most vivid proof of the present fatuous state of mind in regard to this tremendous problem. Of the direct and exciting causes of insanity excessive drinking stood easily first. In 19 per cent. of the whole cases the excessive use of alcohol was the causal factor. This was 10 per cent. less than it had been in 1903. The past year of dull trade had diminished the alcoholic lunacy rate. The proportion of female alcoholics had been steadily increasing until last year it reached 18½ per cent. of the total female admissions. The total number of female alcoholics last year actually exceeded that of the men. The number of cases of general paralysis had been less than in the preceding years. A large number of the cases had been in women and it was a proved fact in all European classes that general paralysis was increasing among both sexes but especially among the women of the uneducated class. The recoveries had been 9 per cent. under the average, this being due to the large number of old, paralysed, and exhausted people among the admissions. The event of outstanding importance in the past year had been the commencement of the process of parting with the rate-paid patients.

---

[1] THE LANCET, Dec. 31st, 1904, p. 1891.

The Carnegie Trust for the Universities of Scotland.

The fourth annual meeting of the Carnegie Trust for the Universities of Scotland was held on Feb. 27th in Edinburgh. The fourth annual report of the executive committee stated that under the scheme of allocation sums amounting to £38,114 12*s.* 4*d.* had been claimed and handed over during the year, making an expenditure for the two years of £58,479 12*s.* 4*d.* The grants for library purposes and for provisional assistance in teaching amounting to £6400 had been fully paid. The grants for buildings and permanent equipment available for 1904, including a balance of £12,635 unexpended in 1903, amount to £33,035. Of these the sum of £20,146 8*s.* 6*d.* has been claimed. At St. Andrews the new buildings for the departments of chemistry and of physics were approaching completion. At Dundee plans were being prepared of a further extension for the accommodation of the department of physics upon the site to which the trust contributed the grant available in 1903. The grant for 1904 had been used for the enlargement of the chemical laboratory and the grants of the three remaining years of the quinquennium were to go towards the erection of a central heating system for the various buildings of the College. The two new buildings at Glasgow for the departments of physics and of physiology, materia medica, and forensic medicine were making satisfactory progress. In Edinburgh a site had been found for the new accommodation for the departments of physics and engineering by the purchase from the town council of the land and buildings of the old city hospital. Claims for grants towards teaching endowments amounted for the year to £11,568 3*s.* 10*d.* In the case of the University of Edinburgh the committee expressed its willingness to further Sir Donald Currie's wishes, expressed in connexion with his recent gift of £25,000 to that University, that £20,000 of that amount should be applied to the establishment of a lectureship endowment fund. The committee has offered to place the income of the capital sum of £10,000 allocated to the University for teaching endowment at the disposal of the University court, to be used in conjunction with Sir Donald Currie's gift. Grants amounting to £9000 had been allocated to various extra-mural schools to be drawn on up to Dec. 31st, 1907, and under the heading of provisional assistance in teaching grants have been offered for the academic year 1904–05 amounting to £635. The scheme of endowment of post-graduate research continues to be carried on. The total expenditure under this heading amounted for the year 1903–04 to £3386 8*s.* The estimated sum for the present year amounted to £5177 10*s.* In the research laboratory of the Royal College of Physicians of Edinburgh, the purchase of which had been announced in the last annual report, steady and satisfactory work had been done in all departments. 35 workers had held places in the laboratory and had been engaged in 47 investigations. Of these 29 were graduates of the University of Edinburgh and nine held grants from the Carnegie Trust. The number of beneficiaries under the scheme for the payment of class fees had been 3075 for the winter session of 1904–05, an increase of 43 over the previous winter session. The total number of beneficiaries since the institution of the trust was 5419. The trust had paid in fees for the summer session 1904 the sum of £14,935 on behalf of 1835 students and for the winter session 1904-05 the sum of £30,871 13*s.* on behalf of 3075 students. The committee recorded with pleasure that during the year 1904 six graduates had refunded fees paid to them amounting to £84 2*s.* The report and the accounts were approved of.

Sick Children's Hospital, Aberdeen.

The twenty-eighth annual report shows that during the past year 2376 cases have been treated—724 as in-patients and 1652 as out-patients. Of the 724 in-patients, which comprise 620 from the city and 104 from the country, 399 recovered, 116 were improved, 57 died, 79 were in the wards at the close of the year, and the balance were removed as unfit, &c. The average stay of each in-patient in 1904 was 32·8 days; in 1903 it was 31·4 days. The average number of beds occupied daily in 1904 was 74·3, compared with 74 in 1903. The average stay during the past ten years of each of the 7321 patients was 37·675 days and the average number of beds occupied was 76·12. The ordinary expenditure for the 12 months was £2850 18*s*. 8½*d*., being an average annual expenditure per bed occupied of £38 7*s*. 5*d*., or an average daily expenditure per patient of 2*s*. 1½*d*. The annual income amounted to £1888 13*s*. 3*d*., or £962 5*s*. 5½*d*. short of the cost of maintenance for the year. The extraordinary income from legacies makes the actual deficit £852 5*s*. 5½*d*. The legacies received during the past two years—£1052 11*s*. 11*d*. in 1903 and £110 in 1904—afford a striking illustration of the untrustworthiness of this source of income and impel the directors yet another year to renew their appeal to the well-wishers and friends of the institution for increased giving to the ordinary channels of income, so that these might be more commensurate with its annual needs.

March 7th

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Yellow Fever.

AT two consecutive meetings of the Academy of Medicine M. Chantemesse has recently discussed this important subject. On Feb. 21st he showed by the recital of some remarkable facts how the theory of the propagation of the disease by mosquitoes agrees, so far as prophylactic measures are concerned, with the conclusions arrived at by medical men of the last century after a series of patient observations. The Academy of Medicine had previously noted the forty-third parallel of N. latitude as the limit of yellow fever[1] and this is the frontier line of the habitat of the stegomyia. The prophylactic measures against yellow fever are the following: the stegomyia must be suppressed in every possible way; both sick and healthy must be protected from mosquito bites by means of masks, gloves, mosquito nets, and gauze window blinds; and all receptacles for water must be kept under surveillance and no stagnant collections allowed in which eggs may be laid or larvæ hatched. A strict watch over cargo is unnecessary except in the case of wet goods, such as moist wood, bananas, or fresh fruit. Ships coming from an infected port should be inspected especially as regards ventilation, the cook's galley, and the stokehold (*chaufferie*), or any other place where pools of water are likely to occur. If no case of yellow fever has occurred on board during the voyage free *pratique* may be granted and without any disinfecting measures being carried out. If one or two cases obviously contracted in the infected port should have developed on board and not have given rise to any others free *pratique* may again be given and no restrictions need be placed on the crew, their effects, or the cargo. If, however, infection has occurred on board precautions must be adopted. The cargo must be removed and the ship thoroughly fumigated with sulphurous acid. If the cargo in whole or in part is of such a nature as to afford [illegible] fumigated in the same way. [illegible] more careful attention than [illegible] yellow fever on arriving in [illegible] ut in ports where there is no lazaretto they may be sent to the ordinary hospital. Finally, M. Chantemesse is of opinion that in France at any rate yellow fever need not be considered as an infectious disease.

Wound of the Right Ventricle; Suture; Recovery.

On Feb. 15th at the Surgical Society M. Delorme read for M. Riche the notes of a case of wound of the cardiac ventricle. The patient was a woman four months pregnant who received a knife stab in the fourth left intercostal space. Two hours later M. Riche operated. He turned up a flap of the whole thickness of the chest wall, including the third, fourth, and fifth ribs, divided at the junction of bone and cartilage. He opened the pericardium, which was full of blood, and exposed the wound which was in the centre of the right ventricle. Catgut points of suture not going through the whole thickness of the cardiac wall were used, the pericardial and thoracic wounds were closed without drainage, and the patient recovered. Some weeks later she aborted.

Foreign Bodies in the Œsophagus.

At the meeting of the Society of Surgery held on Feb. 22nd M. Kirmisson read for M. d'Oelnitz an account of the case of a child, aged 14 months, who had swallowed a 50 centime piece. Radiography showed the coin lying in the œsophagus, just behind the manubrium sterni. Several attempts were made to extract the coin with Graefe's coin-catcher but in vain. Eight days later the child was brought to M. d'Oelnitz who, being acquainted with M. Kirmisson's hook,[2] made use of this instrument and easily extracted the coin. M. Kirmisson took occasion in reporting this case to express his disagreement with those who recommended œsophagotomy and who considered that the hook should only be used in recent cases. He thought that œsophagotomy was a dangerous operation in young children.

Paraplegia following Cocainisation of the Spinal Cord.

At the meeting of the same society held on Feb. 29th M. Walther showed a patient, a young man, who had been operated on some eight months previously, not by M. Walther, for degenerating synovitis of the foot. To anæsthetise him the spinal cord had been cocainised by a lumbar puncture. Three days after the operation the man complained of his legs feeling cold and heavy and on the eighth day he lost all power of movement in them. By the end of the third week he had incontinence of fæces and urine and he continued in this state for four or five months, by which time he regained control over his bladder and rectum. But still he can only move his legs slightly. These symptoms, said M. Walther in conclusion, are evidently due to a typical meningo-myelitis.

The Action of Radium upon Venoms.

[illegible] nces which was held [illegible] of some researches [illegible] ry of M. Chauveau. The subject of research was the action of radium upon venoms, notably those of serpents and of certain batrachians. Serpent venom, which is an albuminoid, is completely destroyed in a very few hours by the action of radium. Moreover, a solution of the venom is freed from all germs, being both microbicidal and antivenomous. The venom of the land salamander, which is alkaloidal in nature, is not affected by radium, neither is that of the toad.

Lupus of the Hand.

At the meeting of the Anatomical Society held on Feb. 27th M. Morestin showed a patient whom he had treated for lupus of the hand. The operation consisted in the removal of the skin from the index, the ring, and the little fingers. The middle finger was removed on account of its being affected with tuberculous dactylitis. The wound was covered with a graft after the Italian method. Now, at the expiration of a year after the operation, the result was very satisfactory M. Morestin laid stress upon the benefits to be derived from a widespread clearance of affected structures in surgical operations done with a view to repair.

March 7th

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Free Supply of Milk for Out-patients of the Children's Hospital.

THE largest children's hospital in Vienna has, in connexion with the Society for the Protection of Infants (Säuglingsschutz), made arrangements for supplying a number of needy families with pure milk for the use of their infants and not long ago acquired premises for the purpose. In the midst of a densely populated district, inhabited chiefly by labourers, factory workers, and small tradesmen, a two-storey house has been built, containing proper rooms for the storage of milk and for the examination of the infants who are taken there. 250 litres of milk are daily at the disposal of the chief medical officer of the institution, sent as a gift from the dairy of the Archduchess Isabella who takes a very great interest in that intervention and the continued improvements of the pavement of streets had reduced the mortality and morbidity to about 50 per cent. of the former rate, besides beautifying the city and making it infinitely more attractive for residents who were interested in health and general culture. Dr. Carlos Finlay in his address as president stated that in the district of Havana, notwithstanding the admission of imported cases of yellow fever from foreign ports, not a single case originating on the island had been recorded. With the experimental proofs that they now possessed that fomites *per se* were incapable of transmitting the disease the inevitable conclusion must be that in the cases which he mentioned infected mosquitoes had been conveyed upon floating bodies by the tide. The Report of the Committee on the Bacillus Tuberculosis in Man and Animals was read by Dr. V. C. Moore. The conclusions reached were that the committee did not feel able to say with what frequency bovine infection of man took place but it was evidently not a rare occurrence. The committee considered that the evidence going to show that such infection did take place was absolutely conclusive and that it not only justified but made imperative the passage of stringent laws by municipal and State authorities for the suppression of tuberculosis in cattle and the prohibition of the sale of meat and milk from tuberculous animals. The meeting was a great success. The association is to meet in the city of Boston, Massachusetts, in 1905.

---

[1] This is in Europe; in North America yellow fever has been observed as far north as 46·50' N.—ED. L.

[2] See THE LANCET, Jan. 14th, p 125.

Instruction in Public Health in Medical Colleges.

The department of medicine of the University of Pennsylvania has organised a series of lectures on the subject of hygiene and medicine of general interest to practitioners. It was originally designed that this course should be for the benefit of fourth year students but invitations to the medical profession of the city are now given. The same university will introduce into its curriculum, beginning Oct. 1st, 1905, a course in public health. This course will include instruction in sanitary engineering; inspection of meat, milk, and other animal products; the sanitary engineering of buildings; social and vital statistics in the United States; and practical methods used in sanitary work, general hygiene, personal hygiene, and sanitary legislation. This is the first attempt in this country to introduce a course of instruction in hygiene into the curriculum of a university.

Tuberculosis among the Jews.

Amongst the numerous paradoxical characteristics of the Jews their relative immunity to tuberculosis has been considered most peculiar. Evidence wherever obtainable shows that they are less liable to the "white plague" than their non-Jewish neighbours, notwithstanding the large numbers among them who have flat chests, ill-developed muscles, and who are anæmic and generally below the standard of physical vigour when compared with the Gentiles among whom they live. According to the "Jewish Encyclopædia"—containing statistics gathered in Russia, Germany, Hungary, Italy, England, and the United States—this view is confirmed. A recent thorough study of the Jewish district of Chicago by Dr. Theodore Sachs leads him to the conclusion that the immunity of the Jew from tuberculosis has been greatly over-estimated. In his opinion the difference is due to the fact, which he discovered, that only a small percentage die in the district in which they have contracted the disease, the rest leaving the city in search of a cure in some climate reputed to be efficacious. In proof of this contention the author shows that of 51 deaths from the disease 26 occurred in persons younger than 15 years of age, while in the period of life between 20 and 40 years, the usual period of greatest mortality, only ten deaths took place. The results of Dr. Sachs's inquiries differ from investigations made in New York by its health department in regard to both the morbidity and the mortality of tuberculosis in Jewish districts. The conclusion reached was that the Jews of this city are proportionately less affected with tuberculosis than the non-Jewish inhabitants, even when we compare them in the same district or the same block. The statistics of New York are much larger than those taken at Chicago and comprise also morbidity and are, therefore, regarded as more trustworthy.

Protective Inoculation against Cholera.

The United States Government laboratories have been engaged in experimental studies on protective measures against Asiatic cholera and have recently published the results. The author of the report, Dr. Richard P. Strong, states that the work was based upon experimental work performed in the Berlin Institut fur Infectionskrankheiten in 1903. The Philippine Islands have furnished the most recent opportunity for a thorough study of cholera and advantage was taken of the severe epidemic there to perfect our knowledge of protective measures. According to Dr. Strong the history of cholera in a tropical country has demonstrated the fact that it is impossible to eradicate, or even to control satisfactorily, the disease by ordinary hygienic methods, such as the purification of the food-supply and the water-supply of infected districts. It was shown by studies made in the Manila laboratory during the period of the widespread infection that the disease was not usually transmitted directly by water but probably more often by food infection. Preliminary trials with Haffkine's method of protective inoculation showed the impracticability of using it among the natives. Consequently, the experimental study now described was undertaken in the biological laboratory in Manila with a view of obtaining some practicable and efficacious form of protective inoculation against the disease. The conclusions reached are as follows: (1) by the autolytic digestion of carefully killed cholera spirilla in an aqueous fluid the receptors become separated from the bacterial cells and may be filtered off in solution; (2) the injection of these free receptors into both man and animals furnishes a means of producing high bactericidal and agglutinative blood sera but the value of these sera is moderate; and (3) the subcutaneous injection into man of such free receptors is a process which is not only free from any danger but one which produces practically no local disturbance and only a slight general reaction and hence the method is a practicable one for producing a cholera serum in man. Owing to the absence of cholera on a wide scale in the Philippines it has been impossible to give the serum a proper test but Dr. Strong, basing his opinions on the statistics of Haffkine in India and the work of Murata in Japan, which show that by the injection of a small amount of the killed organisms a certain degree of immunity against the natural mode of infection is acquired, thinks it probable that by the use of his prophylactic human beings may acquire a good active immunity against the disease.

Feb. 26th.

NOTES FROM INDIA.

(From our Special Correspondent.)

Report of the Pasteur Institute at Kasauli.

The fourth annual report of the Pasteur Institute at Kasauli records a steady advance in popularity. During last year 612 patients were treated, of whom 248 were Europeans and 364 were natives. All these were for bites from presumably rabid animals. In the report the cases are divided according to those bitten by animals proved by experiment to have been rabid, those bitten by animals certified as rabid by a veterinary surgeon or a medical officer, and those bitten by animals suspected to be rabid but for which there was only presumptive evidence. In order to estimate the danger of bites in different parts of the body the cases are further analysed into those bitten on the head or the face, those bitten on other exposed parts, and those bitten through clothing. The last class are the least dangerous and the cases of bites on the head and the face are the most dangerous. As the clothing of the natives is so thin it does not appear to offer them much protection and the natives when bitten do not show the same alacrity as Europeans for immediate treatment. Of the 612 persons treated five cases failed, all natives. They had all been severely bitten and with one exception arrived late for treatment. There were five cases also in which the disease had set in before it was possible to protect them. Other and very important work is carried out at Kasauli. A large quantity of sera for therapeutic purposes was prepared and the bacteriological laboratory was utilised by officers of the Indian Medical Service and the Royal Army Medical Corps for instruction purposes. In addition a considerable amount of research work was done, more especially in connexion with curative sera, the action of snake venoms, cerebro-spinal meningitis, and the improvement of the antirabic treatment.

The Sanitary Improvement Scheme for Simla.

The report of Colonel Bamber, sanitary commissioner of the Punjab, upon the Simla sanitary improvement scheme has been considered urgent by the municipal committee which has recommended the following works for immediate attention: provision of incinerators, connecting all the sullage water of the compounds by an extended sewerage system, provision for dhobie ghâts, sanitary buildings for artisans and coolies, sewerage installation for houses east of Jakko, an enlarged bakery, additional markets, and conversion of native public latrines into automatic troughs. This is a good list and will necessarily involve a large outlay.

Further Large Rise in the Plague Mortality and Spread of the Epidemic.

The plague mortality throughout India has risen enormously during the past few weeks. For the week ending Feb. 4th no less than 36,167 deaths from plague were recorded as compared with 28,104 three weeks previously. The United Provinces, the Punjab, and Bengal are now bearing the chief brunt. The following figures show how the disease has spread: United Provinces, 15,337 deaths as compared with 11,777 three weeks ago; the Punjab, 9472 deaths as compared with 5569; Bengal, 5150 as against 3318; Bombay district, 3111 as against 2886; Hyderabad State, 526 as against 399; Bombay city, 395 as against 192; and Calcutta, 84 as against 33. Later returns show a still further rise in Bombay city (540 deaths for the week ending Feb. 11th) and Calcutta (106 deaths). During the past fortnight also Rangoon has become infected and 25 cases were reported up to Feb. 13th. Madras also has been attacked and several indigenous cases have been reported. Singapore also has been declared an infected port. From the Punjab administration report I find that no less than 327,357 inoculations against plague were performed last year and by an analysis of the cases it was found that the liability to death was two and a half times as great among the uninoculated as amongst those who had had the courage and foresight to be inoculated.

The Bombay Sanitary Association.

The first annual meeting of the Bombay Sanitary Association has been recently held and the report of the year's work shows remarkable energy and enthusiasm amongst those who manage it. The recent exhibition in Bombay gave the opportunity for a health section which was admirably organised and must prove to have been of great educational value. It is hardly to be expected that the association could show immediate results but it has certainly appeared to have awakened a hygienic conscience and a great deal has been done in instructing the masses with regard to a more healthy manner of living. Lectures in the vernacular as well as in English have been given, pamphlets and leaflets have been freely issued, and house-to-house visitation has been energetically made. Not the least remarkable part of the work of this new association has been the admirable and [illegible] ing [illegible] nts [illegible] ion and pecuniary assistance of the corporation and the active support of the Government. Subscriptions have come in freely and the general support which the association has received augurs well for a continuance of the useful work and a furtherance of the objects which its promoters have in view.

The Wadia Home for Nurses in Bombay.

The foundation-stone of the Wadia Home for Nurses in Bombay has just been laid by His Excellency the Governor. The home is for the nurses of the large "J. J." Hospital. 25 years ago there were only two sisters working. In 1890 three English nurses were obtained in addition and some native nurses also assisted. Later more young native women were employed and the Bhownaggree Home for them was established. Subscriptions and a contribution from the Government enabled the nursing staff to be increased further but it has never been sufficient. *Accommodation* for the nurses naturally came to be required and the mother of Mr. N. N. Wadia has generously given a large sum for this purpose. The total cost will [illegible] subscriptions for the support of the various nursing establishments connected with the hospitals in the principal cities in India have never been very generous or extended and if it were not for Government support they would perhaps be in a bad way. It is possible, however, that if the Government gave less freely more support might be obtained from the public and as these hospitals confer such inestimable benefits on the native communities it is not expecting too much to ask them to contribute more freely.

Compulsory Revaccination.

The Madras corporation has adopted the suggestion of the Government in favour of compulsory revaccination for all municipal employés who enter its permanent service.

Feb. 18th.

Obituary.

ROBSON ROOSE, M.D. BRUX., F.R.C.P. EDIN., M.R.C.S. ENG.

Dr. Robson Roose, who died on Feb. 12th, had for a long series of years been well known in London as the medical adviser of very many notabilities in West-end society and in the higher political circles. He was born in London in 1848 and studied medicine at Guy's Hospital and in Paris. In 1870 he took the diploma of L.S.A. and very soon commenced practice in Brighton. In 1872 he took the diploma of M.R.C.S. Eng. and in 1875 that of M.R.C.P. Edin.; in 1877 he obtained the degree of M.D. at Brussels and was elected a Fellow of the Royal College of Physicians of Edinburgh. It is said that while at Brighton he was "discovered" by the late Mr. Edmund Yates, the well-known "society journalist" and man of letters, who introduced him to various influential personages. Removing from Brighton to London, Dr. Robson Roose settled at 49, Hill-street, Berkeley-square, where fortune favoured him so greatly that his services were everywhere in request and he was a familiar figure at social gatherings of the world of fashion. Of late years, however, he had some unfortunate experiences in connexion with the directorship of a commercial undertaking and declining health made it necessary for him to withdraw to some extent from active work.

RALPH HODGSON, M.R.C.S. ENG., L.R.C.P. LOND., L.D.S. R.C.S. IREL.

Mr. Ralph Hodgson of Liverpool-street, Sydney, New South Wales, died very suddenly on Jan. 18th while supervising some repairs which were being made in his motor launch. He was the fourth son of Captain Charles Hodgson, late of the Grenadier Guards, assistant commissioner of the City of London police. He studied medicine at St. Bartholomew's Hospital and took the diplomas of M.R.C.S. Eng. and L.R.C.P. Lond. in 1885, having been already in possession of the dental diploma of the Royal College of Surgeons in Ireland since 1881. In 1887 he went to Sydney and entered upon the practice of his profession at Croydon. Mr. Hodgson was one of the founders of the King Edward Hospital for Seamen and claimed that he [illegible] use of head measurements and [illegible] the identification of criminals in [illegible] n of fine physique, a representative chess player at inter-State [illegible] race with [illegible] engine [illegible] at the [illegible] who is a barrister-at-law.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. Felix, director-general of the Roumanian Sanitary Department.—Dr. G. Piotrowski, *privat docent* of physiology in Lemberg.—Surgeon-General Pful of Hanover.—Dr. Gunther, formerly president of the Saxon Medical Association, at the age of 76 years.

LEGACY TO A RUSSIAN MEDICAL BODY.—The Conference of the Military Medical Academy has decided to accept the legacy made in its favour by K. R. Nedatsk, consisting of two sums—one of 16,000 roubles (£1600) to found a bursary in the name of the testator and the other of 50,000 roubles (£5000) for treatment by means of sero-therapy. The will of the testator is that the capital should be kept intact, the academy simply disposing of the interest.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The result of the voting on the proposals for the reform of the Previous Examination was that the *non-placets* numbered over 1500 and the *placets* over 1000. The proposals of the syndicate were thus rejected by a majority of about 500. It is understood that a majority of the resident members of the Senate voted *placet.*—At a Congregation on March 2nd the following degrees were conferred:—

Doctor of Medicine.—R. H. Urwick, Trinity; and G. M. MacDonald, Christ's.

Bachelor of Medicine.—J. S. Pearson, Trinity; and R. A. Worthington, Clare.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidate having passed the necessary examination has been admitted to the Fellowship of the College:—

Miss A. F. M. Cornall, L.R.C.S. Edin.

The following candidates have passed the primary part of the Fellowship examination:—

J. Campbell, H. H. B. Cunningham, D. Adams, R. M. Bronte, J. D'Alton, P. G. T. Elvery, J. B. Hanafin, F. M. Hewson, J. Molyneaux, C. Sheahan, T. Sheehy, and G. F. Shepherd.

TRINITY COLLEGE, DUBLIN.—At examinations held in Hilary term the following candidates were successful:—

Final in Surgery.—Henry E. M'Cready, Robert Magill, Michael J. M'Auliffe, and Edward G. Scroope.

ROYAL DENTAL HOSPITAL.—Mr. J. Tweedy, President of the Royal College of Surgeons of England, will preside at the annual meeting of the Royal Dental Hospital on Tuesday next, March 14th, at 5.30 P.M.

OBSTETRICAL SOCIETY OF LEIPSIC.—Dr. H. Macnaughton-Jones, formerly University Professor of Midwifery in the Queen's University, has been elected an honorary member of the Obstetrical Society of Leipsic.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. Charles Edward Liesching, L.R.C.P. Lond., M.R.C.S. Eng., was presented on Feb. 17th with an aneroid barometer by the members of the Tiverton (Devon) branch of the St. John Ambulance Association in appreciation of his services as honorary lecturer.

Messrs. C. J. Hewlett and Sons, export druggists, have been awarded a gold medal for their standardised tinctures, drugs, and pharmaceutical preparations at the Cape Town International Exhibition, 1904-05.

AMBIDEXTERITY FROM THE POINT OF VIEW OF THE PHYSICIAN.—On March 2nd, at the rooms of the Royal Statistical Society, Adam-street, Strand, W.C., Sir James Sawyer delivered a lecture on Ambidexterity, pointing out that not only were we not by necessity unidextral but that man in his early development was ambidextrous. This quality was lost partly by necessity and partly by custom and especially in the development of writing and fighting. Early man found that he could fight better with a one-handed than with a two-handed weapon. He then found that it was necessary to keep his heart as far as possible from his adversary. Thus the right side was given prominence. In the use of the pen the right hand was further developed. He went on to urge that although we could not help having a preferred hand perhaps we need not have a neglected one. Ambidexterity could be acquired in many ways, especially by using each hand in turn in all one-handed activities. As preliminary exercises he would recommend writing with the other hand, carrying a stick or umbrella in the right hand on going out and in the left hand when returning, and fencing with the foil at a mark on the wall with either hand alternately. Learning to drive in a nail with either hand was also useful. A fair amount of ambidexterity could be acquired in a few months with gain in physical health and better chances of living a healthy and long life. Incidentally the lecturer mentioned references to ambidexterity by De Quincey and Carlyle and quoted the following from Brown-Séquard: "We have a great many motor elements in our brain and our spinal cord which we absolutely neglect to educate. Such is the case with the elements which serve for the movement of the left hand. Perhaps fathers and mothers will be more ready to develop the natural powers of a left hand of a child, giving it thereby two powerful hands, if they believe, as I do, that the condition of the brain and spinal cord would improve if all their motor and sensory elements were fully exercised." With this Sir James Sawyer said that he was in full accord. The next lecture of the series will be delivered by Sir W. Blake Richmond, K.C.B., on March 16th, at 8 P.M., on Ambidexterity in Art.

ROYAL FREE HOSPITAL, LONDON.—The annual court of governors of this hospital will be held on March 15th. The chair will be taken at 3.30 P.M. by H.R.H. Princess Christian, President of the Hospital, when the annual reports and accounts for the year ending Dec. 31st, 1904, will be presented and the new electric lift and other improvements in the Victoria wing will be opened. The governors and their friends are invited to inspect the wards and the various departments of the hospital during the afternoon. Communications on the matter should be addressed to Mr. Conrad W. Thies, secretary, Gray's Inn-road, W.C.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Revaccination of School Children.

THE Duke of NORTHUMBERLAND is interesting himself in the vaccination question. He has given notice of his intention to ask the Government whether it proposes to introduce a Bill this session for the promotion of the revaccination of children of school age.

A New Vaccination Bill.

In the Commons Mr. PHILIP STANHOPE has introduced a Bill to amend the administration of the Vaccination Acts. The two operative clauses are these:—2. After the passing of this Act an officer of a board of guardians or other local authority, wholly or partly paid for his services out of the proceeds of any rate, shall not institute proceedings or be concerned in legal proceedings against any person for non-compliance with the provisions of any Vaccination Act, unless authorised to do so by a resolution passed by the board of guardians or other local authority employing him, nor until a copy of each resolution in writing, signed by the chairman presiding at the meeting of the board of guardians or other local authority at which such resolution was passed, has been handed to him; and such officer shall exhibit to the justices adjudicating upon a summons taken out by him such copy of resolution when demanded by them or by the defendant or other person appearing on his behalf. 3. An application for a certificate of exemption under the Vaccination Act, 1898, may be made by the father or the mother or either of the guardians of a child liable to vaccination under any Act, and the justices to whom the application is made shall not catechise the applicant, but may, if not satisfied that the applicant has a conscientious objection to vaccination, administer, or cause to be administered, the usual oath; and if the applicant declares on oath that he or she believes that vaccination would be prejudicial to the health of the child in question, a certificate of exemption shall be granted, at a cost not exceeding one shilling, without further question or remark.—Mr. STANHOPE has the support of Mr. BROADHURST, Mr. CHANNING, Mr. MAURICE LEVY, and Sir CHARLES MCLAREN.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 1ST.

The Inspection of Meat in London.

Mr. FIELD asked the President of the Local Government Board whether he was aware that a master butcher in Ealing recently [illegible] purchased a number of pigs in the Central [illegible] London, E.C., which he was informed were [illegible] Islington Market where they would undergo examination in the ordinary course, and having purchased these pigs at top market price they were delivered at Ealing where the inspector condemned two heads as being affected with tuberculosis, and that a summons was now pending with a view to secure a criminal conviction, and whether he would make inquiries in this case in order to insure uniformity of inspection and thereby safeguard a trader from criminal proceedings in respect of meat purchased *bonâ fide* passed by one inspector and subsequently confiscated by the inspector in another district.—Mr. LONG replied: I have made inquiry with respect to this matter. I understand that the pigs were not cut up at the Islington Market or at the Central Meat Market, and the medical officer of health of the City points out that it was quite possible that disease which would not show itself in the carcass would become apparent after cutting up. I am informed that proceedings in the case are now pending before the justices and hence I cannot take any further action with regard to it. But I may state that one of the medical inspectors of the department is engaged in inquiring into the methods of meat inspection in London with a view of reporting to me on the subject. I may add that the Ealing town council has issued a circular to the butchers in the borough in which it states that the sanitary inspector may, at the request of a butcher, visit his premises and inspect any meat which has been delivered to him, as to the condition of which he may be doubtful, and that in the event of any of it being found to be diseased the inspector will take steps to have it destroyed in the manner prescribed by the law. The town council points out that in such a case the risk of exposing for sale meat unfit for human consumption would be minimised.

Purity of Foods.

Sir CUTHBERT QUILTER asked the President of the Local Government Board whether he was now able to announce the course which it was proposed to adopt with a view to giving effect to the large and [illegible]

Colonel SADLIER asked the President of the Local Government Board whether, in view of the fact that the charge made for certificates of death for members of trades unions was 2s. 7d. each while the charge [illegible] he would consider the [illegible] 1s. in both cases.—Mr. [illegible] but legislation would [illegible]

THURSDAY, MARCH 2ND.

Irish Dispensary Districts.

Mr. JOSEPH NOLAN asked the Chief Secretary for Ireland whether, in [illegible] arrived at by the Local Government Board in regard to the matter.—[illegible] who replied, said: The inquiry [illegible] last year. In September the Local [illegible] under seal rearranging the dis- [illegible] then made to the King's Bench [illegible] quash the Board's Order and was [illegible]

FRIDAY, MARCH 3RD.

Irish Local Government Board and Maternity Nursing

Mr. JOHN O'DONNELL asked the Chief Secretary for Ireland whether there had been any exceptional circumstances to justify the granting of an inquiry into the necessity for an official maternity nurse in Ballyhaunis dispensary district; whether he would state on what portion of the evidence Sir Acheson M'Cullagh based his recommendation to have a sealed order issued in connexion with the matter, and [illegible] union regarding the necessity for [illegible] the Ballyhaunis dispensary district [illegible] being made, and that Ballyhaunis [illegible] two medical men and two maternity [illegible] of the fact that the appointment of such a nurse was in opposition to the public opinion of the district. [illegible] ever, available for the sick poor free of charge. My right honourable friend stated on Feb. 23rd that it is not proposed to withdraw the sealed order.

MONDAY, MARCH 6TH.

Medical Inspectors in Scotland.

Mr. WEIR asked the Lord Advocate whether he was aware that [illegible] of that of [illegible] the Local [illegible] even such [illegible] vote, and [illegible] inspector [illegible] sence, the [illegible] l be con [illegible] ed in the [illegible] retary for Scotland has no proposals to make at present in the direction suggested.

Recommendations of the Committee on Physical Deterioration

Mr. WEIR asked the Lord Advocate whether the Secretary for Scotland would consider the [illegible] medical officers, sanitary inspectors, a[illegible] the opinions of the Committ[illegible] ventilation and the bringing [illegible] dissemination of information on these subjects.—The LORD ADVOCATE answered: The Secretary for Scotland will consider whether any official communication relative to this report can be made to the local authorities in Scotland.

Mr. WEIR put a similar question to the President of the Local Government Board and Mr. LONG replied: I have given consideration to the honourable Member's suggestion and I have not at present seen my way to adopt it.

Restrictions on the Employment of Women.

Sir JOHN GORST asked the Under Secretary of State for Foreign Affairs whether he would lay upon the table of the House a return [illegible] before and after [illegible] known to [illegible] tion in the [illegible] ther Correspondence respecting the International Labour Conference at Berlin, Commercial (No 10, 1890)." The Secretary of State will be happy to bring the information up to date if the right honourable Member desires it.

Physical Condition of School Children.

Sir JOHN GORST asked the Secretary to the Board of Education [illegible] code making the pay- [illegible] paid.—Sir WILLIAM ANSON sa[illegible] has the legal power to requir[illegible] public elementary schools. [illegible] right honourable Member ha[illegible] effect of its putting it into operation would be. The organisation of any such system as is suggested in the question must take some time to complete and in the meanwhile the public elementary schools throughout the country would be deprived of Government grant. The Board does not propose to insert any such provision in the new code.

A Prison Case.

Mr. CLAUDE HAY asked the Home Secretary whether his attention had been called to the recent case of a female prisoner having had her hair cut while awaiting trial and whether he would state what steps he had taken in the matter.—Mr. AKERS-DOUGLAS replied: Careful inquiry was made into the case as soon as attention was called to it (which was done by the girl's father on Feb. 20th) and I find that sanitary considerations rendered the cutting of the hair necessary. The woman was examined on reception by the deputy medical officer of the prison who found her [illegible]

TUESDAY, MARCH 7TH.

Sore throat and Milk supply.

[illegible] regard to the fact [illegible] of Glasgow, stated [illegible] Hospital in that [illegible] stock at the farm from which the milk-supply was obtained, he would consider the [illegible] would secure the [illegible] of milk to public [illegible] of the Local Govern- [illegible] duties of sanitary [illegible] d, those officers are [illegible] least once in every [illegible] appears to be unnecessary.

Notes, Short Comments, and Answers to Correspondents.

THE TRUTH ABOUT VACCINATION.

UNDER the above heading the publishing committee of the Association of Public Vaccinators of England and Wales has issued a little pamphlet which is admirably adapted to catch the ears of those who may have been led away by the specious statements of antivaccinationists. It is written in a popular style and costs 1*d.* There are two illustrations, reproductions of photographs, the one being of a case of small-pox in an unvaccinated person and the other of a case of small-pox in a vaccinated person. The pamphlet is not controversial but states simple facts and, except in the case of the *fanatical antivaccinationist who is beyond any form of argument,* should convince any waverer. We hope that it will be widely distributed for it is an excellent publication.

A QUEER KIND OF DRAUGHT.

To the Editors of THE LANCET.

SIRS,—I attended a midwifery case yesterday and while waiting for

the "after-pain" *mixed with brandy. I expressed my horror and forbade* it to be given but when I was at the other end of the room I heard the patient say, "It was nasty," and found that the "nurse" had given her the draught of placental blood and brandy. I agree with the patient and say it is nasty. Needless to say, these were foreign people.

I am, Sirs, yours faithfully,

Widegate street, E.C., Feb. 27th, 1905. ISAAC GEORGE.

VICARIOUS MENSTRUATION.

To the Editors of THE LANCET.

SIRS,—I have lately been attending a case of "epistaxis" in a girl aged 20 years. The bleeding only occurs at the monthly periods, at which time she loses but little blood in the ordinary way. As she is extremely anæmic the case is interesting from the treatment point of view. She has been taking the usual tonics prescribed in cases of anæmia but I am not satisfied with the progress made. Could any of your readers advise me of any special treatment in a case of this kind?

I am, Sirs, yours faithfully,

Great Glenn, Leicester, March 1st, 1905. FRANCIS G. BENNETT.

THE IDENTIFICATION OF TYPHOID FEVER.

"X. Y. Z." sends us an interesting letter recalling some old hypotheses with regard to typhoid fever. He alludes in particular to the claims of the late Dr. Alexander P. Stewart first to have made it clear that typhus and typhoid fever were two essentially different diseases. There is a footnote in Sir Thomas Watson's classical work to the following effect. "It is a bare act of justice to record that so early as the spring of *1840* a paper was read *before the Parisian Medical* Society by Dr. Alexander P. Stewart in which the main distinctions between typhus and typhoid fever were clearly set forth." "X. Y. Z." tells us that he worked under Dr. Alexander Stewart at this time and well remembers the attention that he paid to the distinctive symptoms of *typhoid fever. He also points out that in the fourth* edition of Sir Thomas Watson's "Medicine" typhoid fever is stated not to exist in the tropics, although he and his coevals had excellent reasons for knowing that this was not the case.

MOSQUITOES AND YELLOW FEVER.

As already mentioned in THE LANCET of Jan. 21st, p. 200, the second annual convention of the American Mosquito Extermination Society was held in New York and Brooklyn on Dec. 15th and 16th, 1904, and the papers that were read included one by Dr. Quitman Kohnke, health officer of *the city of New Orleans, on the Transmission of* Yellow Fever by Mosquitoes. This paper, with numerous pictorial illustrations, is published in the *Scientific American Supplement* of Feb. 11th. *Dr. Kohnke says that the method of infection in yellow* fever is in many respects similar to the process by which malaria is communicated. Formerly it was believed that yellow fever was conveyed by contact either with patients or with articles infected by them, the so-called fomites, but the experiments conducted for the American Government in Cuba demonstrated the harmlessness of fomites by the placing of three young American men for 20 consecutive nights in a room to sleep upon and under bedclothes soiled by previous use in the yellow fever hospital. The room was kept moist and warm and garnished with articles taken from fatal cases of yellow fever, so that there was intimate contact with articles freely exposed to possible infection, but mosquitoes were excluded and no person caught the disease. Subsequently four out of seven of the persons experimented upon were infected by means of the mosquito. In a room prepared so as to exclude all possibility of infection by fomites inoculation by mosquitoes promptly produced an attack. Yellow fever, continued Dr. Kohnke, is conveyed by the stegomyia fasciata, but the germs of the disease can be taken up by the insect only during the first three or four days of the fever; after that time the blood of the patient cannot infect the mosquito. The germs require about 12 days to migrate from the stomach of the insect to the salivary glands, from which they may be injected through the mosquito's biting organ into the human blood stream. Mosquitoes after becoming infectious are capable of inoculating the disease into the human subject at intervals of three days (period of feeding) for practically an indefinite time. Screening the patient from mosquitoes during the first four days of fever (before the diagnosis) or killing all mosquitoes in the room before the twelfth day after their possible infection would certainly prevent a second case, but in practice this cannot be accomplished. The extermination of the stegomyia mosquitoes in localities infected or liable to become so would be much easier than the screening of all fever cases. Water cisterns are known to be breeding places for the stegomyia and ought to be screened. It is estimated, however, that about 75,000 of these cisterns exist in New Orleans and that very few are screened. In quarantine measures against yellow fever, concluded Dr. Kohnke, destruction of mosquitoes is exceedingly important, being second only to the detention for five days after exposure of those who are not immune; these two precautions are the only essentials in quarantine measures against the disease.

A NEW SURGICAL DRESSING.

WE have received from Mr. A. Strauss-Collin of Bush Lane House, Cannon-street, London, E.C., a sample of a new surgical dressing called "vulnoplâtre" which would appear to possess some advantages as a first-aid dressing and in minor surgery. The part of the dressing intended to be placed next the wound consists of a widely perforated waterproof fabric with an adhesive margin for affixing to the skin. Above this is a layer of cotton-wool and above this again the final covering of the dressing. This combination of plaster, cotton-wool, and bandage is certainly ingenious and deserves careful trial. The inventor claims for the dressing thorough absorption and non-retention of discharges.

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to acknowledge the receipt of the following additional contributions?

I am, Sirs, yours faithfully,

A WARNING.

To the Editors of THE LANCET.

SIRS,—Please warn medical men against a man who looks about 50 years of age, is stoutly built, of medium height, round faced; when seen he had light-coloured hair, was clean shaven, except or a small light-coloured moustache, and had an ecchymosis of the left conjunctiva. He speaks with a moderate American accent, says he is a doctor, and skilfully explains his call as due to what he has heard from a well-known medical man in a distant—perhaps colonial—city, whom he will be sure his intended victim knows; and after conversation on general subjects he winds up with a plausible tale of requiring the temporary loan of a moderate sum (for an exigency of the morrow) which he loathes to seek from pawnbroker or money-lender, but will be so grateful to receive from his medical host; and if desired will leave a valuable article with the lender as a proof of his good faith and return the loan in a couple of days. Should the loan be made repayment would fail, and the "proof of good faith" would be found of dubious value as compared with the loan.

I am, Sirs, yours faithfully,
MEDICUS.
March 7th, 1905.

THE OLD EPSOMIAN REGISTER.

Dr. George Francis Longbotham, recently of Birtley, Dr. Cecil Owen Gray, recently of Sutton Coldfield, and Dr. Orme Stirling James Kellet, recently of Victoria-park, N.E., are requested kindly to communicate their changes of address, for use in an Old Epsomian Register to be issued shortly, to Mr. Edred M. Corner, F.R.C.S., 37, Harley-street, W.

◆

R. H.—1. The treatment of pain following extraction of the teeth depends upon the cause of the pain. If due to suppuration in the tooth socket it must be frequently syringed with an antiseptic lotion and, if necessary, packed with gauze. Pain often arises from undue laceration of the surrounding tissue during the operation; in these circumstances hot fomentations may be used and an anodyne mouth wash prescribed. After all operations of tooth extraction an antiseptic mouthwash should be used. 2. All handbooks of physiological chemistry supply the information which our correspondent seeks. "Food in Health and Disease," by Dr. I. Burney Yeo (Cassell and Co.); "The Principles of Dietetics," by Dr. Robert Hutchison (E. Arnold); and "Physiological Chemistry," by Dr. W. D. Halliburton (Longmans), might be consulted.

Practitioner (whose letter bears the Exeter post-mark).—If our correspondent will be good enough to supply us with his or her name and address the question as to the publication of his or her communication shall receive consideration.

Scot.—There is not the slightest difficulty in producing complete anæsthesia by "gas" but our correspondent is strongly advised not to seek the services of any but a properly qualified medical man.

Renlim.—We have not heard of the "cure" under that name. The general wording of the claims to utility suggests that it is a quack affair.

Dicus.—We have no special information but are none the less certain from the nature of the "Professor's" apparatus that he is the usual charlatan.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II of 1904, which was completed with the issue of Dec 31st, *and the Title-page to the Volume,* were given in THE LANCET of Jan 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of
subsc ased rates, on this or on
any c d. The Proprietors of
THE d, and continue to pay,
the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

The Milroy Lectures
ON
INDUSTRIAL ANTHRAX.

Delivered before the Royal College of Physicians of London on March 7th, 9th, and 14th, 1905,

BY T. M. LEGGE, M.D. OXON., D.P.H. CANTAB.,
HIS MAJESTY'S MEDICAL INSPECTOR OF FACTORIES.

LECTURE I.

Delivered on March 7th.

MR. PRESIDENT AND GENTLEMEN,—Knowledge of the incidence of industrial anthrax in this country has been greatly increased as the result of Section 73 of the Factory and Workshops Act, 1901 (previously Section 29 of the Act of 1895), requiring every medical practitioner attending on, or called in to visit, a patient whom he believes to be suffering from anthrax contracted in a factory or workshop to notify the case forthwith to the chief inspector of factories at the Home Office. The notification of the practitioner usually states merely that the case is one of anthrax. Further data are obtained in every case by inquiry a few days later both by the certifying surgeon and by the inspector of factories. During the six years 1899 to 1904, both inclusive, there have been thus reported at least 261 cases of anthrax contracted in factories or workshops or so intimately connected with such conditions that I have not thought it wise to exclude them. I have commenced with the year 1899 because since then information has been obtained of the great majority of cases which have occurred. Between the years 1896, when the enactment first came into force, and 1898 cases were reported—13 in 1896, 23 in 1897, and 28 in 1898—but there is little doubt that owing to ignorance of the requirements of the section there was failure to notify some cases which occurred. Taking the figures as a whole they can be distributed in four main divisions.

TABLE I.

Industry.	Males	Females.	Total.	Fatal.	Per cent.
Worsted and wool	70	18	88	23	26·1
Horsehair and bristles ...	53	17	70	17	24·3
Hides and skins	86	—	86	21	24·4
Other industries	15	2	17	6	35·3
—	224	37	261	67	25·6

Going more into detail as to industry the bulk of the cases in wool have occurred in the processes of wool-sorting, wool-combing, and spinning carried on as independent industries or as preliminary stages in the manufacture of carpets, blankets, and rugs, and of felt; in horsehair they have occurred principally in hair-combing for stuffing purposes and in brush-making; in the hide and skin industry, while the incidence has been mainly at the docks, in warehouses, and tan-yards, isolated cases have been noted in the making of leather articles. The cases included under other industries are interesting. This heading includes isolated cases among workers of horn and persons employed in rag-sorting, in unloading corn, in carrying sacks of potatoes, in a fruit warehouse, in the railway station, and in the manufacture of chemical manure. The total number of persons employed in wool, worsted, and shoddy in the United Kingdom in the year 1901 is stated to have been 259,909 (106,598 males and 153,311 females).[1] Of this large number, however, only 1171 (1164 males and seven females) are classed as being engaged in sorting, and 3093 (1882 males and 1211 females) in combing, the dangerous kinds of wool under the special rules for wool-sorting and wool-combing (Van mohair, mohair, alpaca, pelitan, cashmere, Persian and camel hair), making a total of 4264 persons incurring special risk. At least 64 of the cases occurred among persons employed in the sorting and combing processes of the scheduled dangerous classes of wool. I have excluded from this number cases of outside infection conveyed to others by workers manipulating these wools and

vers, even when these occurred

wools were manipulated and

ection from insufficient separation of one process from another. On the number (4264), therefore, exposed to risk, taking these 64 cases, the figure of attack is 1·3 per cent. or 0·21 per cent. per annum. In horsehair factories, in all processes, the total number employed in the year 1901 was 2206 (724 males and 1482 females). The number of cases of anthrax in horsehair factories was at least 40. I have excluded from this figure altogether the cases which occurred from the use of horsehair and bristles in brush factories. Estimated in the same way as for wool, the figure of risk in the horsehair industry is 1·8 per cent., or 0·3 per cent. per annum. The risk in horsehair factories generally, therefore, stated in this way shows itself to be greater than in wool, when the figures dealt with are limited to those manipulating the scheduled dangerous classes. For particular factories, both of wool and horsehair, *a very much higher attack rate could be given.*

Knowledge of the population of the workers throughout the kingdom is necessary to see whether incidence of anthrax follows closely the lines of relative density of population in the particular industry. This is brought out in the following table, where for each of the counties in England the numbers employed in wool, in horsehair, and in leather are inserted. The figures for horsehair do not include persons employed in brush-making. The number of these is 5365. So far as I have been able to ascertain, however, only three or four of the cases included under horsehair can be attributed to bristles. The figures as to persons employed are least satisfactory for the hide and skin industry. They include all the tan-yards but it is probable that only a very small number of those employed in docks or in wharves and warehouses, among whom incidence of anthrax is greatest, are included. Table II. shows the number of persons employed in: (1) wool, worsted, and shoddy factories; (2) horsehair factories; and (3) leather in the several counties of England; and the number of cases of anthrax in the six years 1899–1904. (The figures for (1) and (2) are those of 1900 and for (3) of 1898.)

In the whole of Scotland among 29,256 persons employed in wool three cases of anthrax were reported in the corresponding six years (two in Ayr and one in Lanark); among 794 employed in horsehair nine cases (all in Glasgow) were reported. No cases were *reported among the 15,563 persons* employed in leather. One case from manipulation of hides occurred in Swansea.

Incidence of anthrax on persons employed in wool is centred almost entirely round the Bradford district of the West Riding and in Worcestershire. No case at all has occurred in the woollen factories of the Stroud Valley in Gloucestershire, Wiltshire, Somerset, and Devon, representing a population of 7000; and again in the whole of Scotland, where nearly 30,000 are employed, only three cases have been reported. This is explained by the fact that, except in the two counties named, the nature of the manufacture does not involve the use of dangerous classes of wool in the raw state from Asia Minor and Persia to be described presently. In the cloth factories of the Stroud Valley and in Scotland colonial wool chiefly is manipulated. Distribution of the cases from manipulation of horsehair follows much more closely the population so engaged which suggests that the dangerous classes of hair from China, Russia, and Siberia are more generally used. Discrepancies

number of persons employed in

similar to those noted in wool.

Surrey,

ire, and

number

in this

industry is mainly confined to the ports of London and Liverpool.

The fatality of the reported cases (25·6 per cent.) is probably higher than would be expected by medical men having knowledge only of cases treated in hospital and less than that expected by the general lay public which believes it hardly possible for recovery from anthrax to take place. It seems, however, to be that which is to be anticipated of anthrax when all cases are included and when the type is mainly external. In Italy,[2] where anthrax is notifiable, in the 11 years 1880–1890 there is record of 24,052, of which 5812 proved fatal—24·1 per cent. In St. Denis and the department of the Seine,[3] between 1886 and 1893, among 123 cases there were 35 deaths—28·4 per cent. Of 91 cases in the horsehair industry in Germany 29 proved fatal—31·6 per cent. Wilhelm Koch[4] collected particulars of 1473 published cases of malignant pustule in which the result was stated and of these 472 died—32 per cent. He adds, however, that these figures must relate to many cases where diagnosis was not made until late and treatment was therefore deferred. Of the 261 cases only six, all of which occurred in Bradford and were all fatal, appear to have been of the internal type. In 248 of the cases the situation of the pustule is stated and this may be grouped as follows:—

TABLE III.

Situation.	Number.	Per cent.
Head and face	108	43·5
Neck	103	41·5
Upper extremity	31	12·5
Lower extremity		1·2
Trunk	3	1·2

According to the occupation so in a measure does the situation of the pustule vary. The above list represents cases where infection arises mainly from dust. In the hide and skin industry, however, the pustule was situated on the neck in 49·4 per cent. of the cases as compared with 29·5 per cent. in wool—a difference to be accounted for perhaps by carrying of the hides on the shoulder. The arm, as might be expected, is much more frequently selected as the site of the lesion when the disease is contracted from work connected with the disposal of a carcass, although even then, apparently, it is less frequent than on the face. In 923 cases particulars of which were collected by W. Koch[5] this is brought out (Table IV).

TABLE IV.

Situation.	Number.	Per cent.
Head and face	447	48·4
Neck	45	4·8
Upper extremity	370	40·0
Lower extremity	26	2·8
Trunk	35	3·8

He further states that of the cases on the upper extremity the situation occurred most frequently on the fingers and the hand. In only one of the list I have prepared was the finger affected. In the anthrax districts of Thuringen, in 209 cases the pustules were situated 74 times on the face, 53 times on the arm, and 51 times on the hand and the fingers. The accident of situation is of considerable moment in determining the severity of the disease. Thus in the cases under review of 13 on the upper eyelid six were fatal—46 per cent.; of 103 on the neck, 31—30 per cent.; of 19 on the forehead, 2—10·5 per cent.; and of 31 on the upper extremity (including the shoulder), 4—12·9 per cent. Inability often to venture on an operation, absence frequently of the diagnostic sign of local necrosis, and the looseness of the cellular tissue account for the high fatality where the upper eyelid or the eyebrow is affected. And even in recovery from the local lesion in this situation extensive sloughing of the eyelid often results. Other figures,[6] based on 180 observations, give the mortality on the head and the face as 26·3 per cent., on the trunk as 22·7, on the neck as 18·5, on the upper extremity as 13·8, and on the lower extremity as 5·1.

The figures which I have given for this country exclude the cases which have occurred to the numerous class of persons who come into contact with animals infected with anthrax during life or have taken part in their slaughter and disposal of the carcass. Unfortunately, in no country can more than a guess be made of the number thus engaged who suffer. In Great Britain the annual returns of the causes of death published by the Registrar-General are of material help. Table V. shows the number of registered deaths from anthrax since 1882 and since 1899 the large share of them borne by those due to factory or workshop conditions.

In 1901 deaths not due to factory conditions were those of a butcher and a fireman in the merchant service; in 1902, of two farmers, a shepherd, and an auctioneer and valuer (the latter had assisted in dressing a dead carcass); and in 1903 of a grocer's assistant, a farm labourer (contracted from bone manure), a butcher, and a gamekeeper. The figures show a marked increase in the decade 1894–1903 (140 deaths) as compared with the previous one (90 cases). Comparison with other countries is not possible as I cannot find that deaths

Note: Cases of Anthrax are for the 6 Years 1899 to 1904, inclusive.

from anthrax are tabulated separately in either France or Germany. Some information on the point, however, is given in the annual reports on diseases of animals in Germany[7] where it is stated (although the figures do not profess to be complete) that in the decade 1894-1903 901 cases of human anthrax occurred, of which 128 were fatal. In 442 of these only can the occupation of those attacked be made out, this number including 312 employed in disposing in one way or another of carcasses of animals which had died from the disease—51 farmers or farm labourers, 25 shepherds or cowherds, 26 horsehair workers, 9 tanners, 7 veterinary surgeons, 4 meat inspectors, 6 butchers, a gamekeeper, an estate agent, a shoemaker, and a person employed in a foreign lamb-skin store. In Austria of 250 cases treated by Graef[8] and two other surgeons nearly all were employed on the land.

TABLE V.

1892	5	1	6	1903	15	1	16	12

With the exception of this country, in all other countries of the world probably anthrax in the human subject is derived much more from contact with the carcass of a dead animal than from the spores contained in the wool, horsehair, hides, and skins of animals imported from distant countries. It is important therefore to ascertain as nearly as can be done the country of origin of the material which conveys anthrax to the factory workers in Great Britain. The source of the suspected material so far as it can be shown is brought out in Table VI.

A mere statement of the source and origin of the infected material which gave rise to the cases in the last six years conveys little information that is surprising unless this is interpreted in the light of the amounts imported from the various countries. The diagram I have prepared[9] shows the value of the amounts of wool, of horsehair, and of hides and skins imported in 1902 in pounds sterling from every country exporting more than an amount equivalent to £10,000. The diagram relates solely to imports and regard has not been had to the very considerable quantities which are re-exported. In the case of wool this is nearly one half, but it would have been impossible for me to have prepared a table showing the amount of material from each country which was consumed in this. The figures show the values of the material shipped from the various ports in the different countries. (See Fig. 1.) There can be no doubt that the considerable amounts from France, Belgium, Holland, and Germany include material which, so far as the country of origin is concerned, ought to be added to that from Persia, Turkey, &c. While I have taken the value of the imports for one year only the number of cases of anthrax attributed to the material from the countries are those of six years. Notwithstanding these limitations to be put upon the diagram it is at once apparent that in the case of wool a small fraction of the total quantity imported has conveyed all the infection. No single case has with certainty been traced in the six years to wool from Australia and New Zealand which in the year 1902 amounted to 417,442,529 pounds, valued at £13,537,457. On the other hand at least 30 cases with certainty, and possibly 40, have occurred from use of Persian wool valued in 1902 at £13,159. At least 21 cases again have occurred from use of mohair and Van mohair imported from European and Asiatic Turkey, the value of which in the same year was £746,818. In horsehair at least 22 cases are traceable to material from China, valued in the year in question at £40,758, or, if bristles be added, at £188,650, and several cases also to Russian or Siberian material valued at £266,497. In hides and skins imported in the wet condition (mainly from Italy and South America through the ports of Germany, France, Holland, and Belgium) only two cases could with any certainty be traced, although such material in 1902 was valued at £1,595,109. In dry hides, on the other hand, 19 cases were due to manipulation of material from China valued in 1902 at £87,989, and a similar number from Bombay and East Indian raw dry hides valued at £265,422.

Having thus shown the part played by the introduction of raw foreign material in the production of anthrax in man I turn to the information available which will throw light on the occurrence of anthrax in animals in these countries, especially in Asia, and on the conditions which favour its spread. These will be found, I think, in conditions of soil, of climate, and equally also in the primitive nomadic life of many of the inhabitants which takes no thought of rational preventive measures. Anthrax in animals is common in all parts of the world. Official figures[10] showing the gross number attacked in such countries as make returns are set down in Table VII. for the years 1901 to 1903.

In France, Hungary, and Sweden the returns are made, not of the number of animals attacked, but of the number of infected farms, and of those in France there were in the three years 416, 395, and 491 respectively; in Hungary 1974, 2158, and 2754; and in Sweden 224, 218, and 179. From one other country in Asia statistics of the prevalence of cattle diseases are given—namely, in India. The numbers of animals that died from anthrax in the North-West Provinces and Oude, North and South Punjab, the Bombay

Asiatic Russia	4,200	6,802	6,886

Presidency, Bengal, Burma, Sind, Rajputana, Madras, and Berar are stated to be as follows:—[11]

TABLE VIII.

—	1899	1900	1901	1902	1903
All animal diseases	343,906	304,931	249,691	228,606	258,419
Anthrax	33,667	36,070	25,997	28,081	30,715

Although these figures may be, and probably are, inaccurate the statement remains in the report that rinderpest and anthrax are the "two most prevalent fatal diseases of Indian cattle." There is an inclination always to doubt the accuracy of statistics on anthrax inasmuch as all sudden deaths of animals which cannot be otherwise accounted for are often ascribed to it. Still, the figures which have been given are separated from the other recognised animal diseases such as rinderpest, cattle plague, foot-and-mouth disease, &c. In the recent Tibetan mission[12] it is stated that anthrax chiefly reduced the number of yaks which accompanied the force from 3000 to 1450. Too much stress must not be laid on the greater number attacked in one country over another in the absence of knowledge of the number of animals in each country. Table IX. shows the actual incidence of the disease per 10,000 of each class of animal. I can only give the figures for Germany and Great Britain.

FIG. 2.

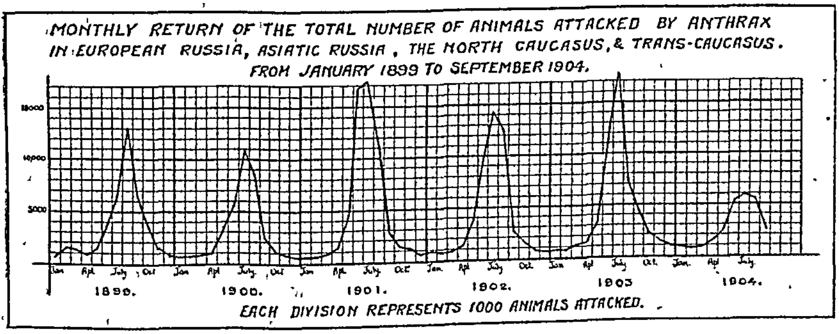

TABLE IX.

Country.	Year.	Horses.	Cattle	Sheep	Goats	Swine
Germany ...	1903	0 36	2 11	0 35	0·03	0 08
Great Britain	1903	Not stated	1 2	0 02	Not stated	0 8

Although this is the average for the whole of the countries named, incidence in particular districts is far greater. Thus among cattle in the district of Düsseldorf it was 11·15 per 10,000, in Zwickau in Saxony 8·8, in Chemnitz (also in Saxony) 8·5, and in Anhalt 6·6. In this country in 1903 in Haddington it was 15·4 per 10,000 and in Aberdeenshire 4·9. Interest to us centres round the large figures obtained from Russia. In the 59 districts in European Russia from which returns were received in the month of August, 1904, cases of anthrax were only absent from three of them and in the 13 districts of Asiatic Russia they were absent from four. The importance of the figures in establishing the law which I believe underlies the whole question of the incidence of anthrax among animals in Asia and in man in this country is brought out by distributing the cases month by month over a period of years as has been done in the following curve. (See Fig. 2.)

Until March of each year there is practically no change in the incidence; there is then an enormous development of the disease, reaching its maximum in July and August, followed by a rapid fall in September and October; in November and December the same figure as that for the early months of the year is reached. This same curve of seasonal influence is apparent, though less marked, in the figures showing incidence of anthrax in Germany since 1885. In contrast to this figures taken quarterly in Great Britain show least incidence of anthrax in the third quarter, July, August, and September. Thus, of a total of 4250 outbreaks in the six years 1899–1904 there occurred in the first quarter 1114, in the second 1166, in the third 850, and in the fourth 1120. As is to be expected in countries where incidence of anthrax is greatest in the hot summer months and where industrial conditions are not predominant incidence on man is subject to the same law and is dependent on direct transmission from animals to man. Thus in Italy of 11,102 cases of malignant pustule reported in Italy in the five years 1892–96 there occurred in the first quarter of the year 1482 cases, in the second 1398, in the third 5286, and in the fourth 2936.

It is interesting to see whether in this country there is any corresponding fluctuation of the disease in man such as occurs in animals in Asia (for what holds good of seasonal influence in European and Asiatic Russia may be assumed to be the same in all countries in Asia exposed to like high summer temperatures). Any close relation between the two must be interfered with, firstly, because factory work at home is continuous all the year round, and secondly, material is stored for varying periods both in Asia and in this country and such as is collected in the summer months in Asia will not necessarily be handled at a corresponding later date here in the factory. The fact that the average number of cases in each of the four months—July to October—is 15·1 and for each of the eight other months is 25·7 points slightly to reflection of the lessened incidence among animals in the winter months in Asia.

---

[11] Annual Administration Report of Civil Veterinary Department in India.

[12] Report on the Working of the Army Veterinary Department with the Sikkim Tibet Mission, by Lieutenant-Colonel R. Moore, Simla, 1904.

The simplest explanation of the facts stated is seasonal variation in temperature and all that this means in changes in the soil and vegetation. We know of the anthrax bacillus that its greatest development takes place at a temperature of 35° C., that multiplication is arrested below 12° C. and above 45° C., and that cooling below the freezing point does not kill it. Spores are most readily produced at a temperature of 32° C. Below 18° C. and above 42° C. the capacity for sporulation ceases. In studying the possible saprophytic growth of the bacillus Koch[13] found that excellent media for its growth could be obtained from emulsions of seeds rich in starch, such as barley, wheat, peas, and grass, and from the fresh juice of potatoes, turnips, &c. Living plant cells do not form a suitable soil but water in which hay and straw have been allowed to decay, if neutralised or made slightly alkaline, became a suitable medium. Possibly the presence of chalk in the soil by neutralising the acids produced in decay may help to render suitable soils otherwise unfitted for the bacillus to develop in.

The characteristic of anthrax specially to infect certain districts has been known for centuries. Long before the bacillus anthracis was discovered as the *causa causans* the epidemiology of anthrax had been studied in many different countries by Hewsinger,[14] especially in Siberia and Germany, with results which led him to the conclusion that the conditions of climate and soil which favoured the development of anthrax in animals were the same as those which favoured the development of malaria in man. In Siberia it was most commonly met with on the salt grass steppes, in the river valleys, and round the bitter lakes. He had noted that its occurrence never failed on land rich in organic matter and liable to putrefaction, such as is found in the impervious peaty moorland soils with tendency to the formation of pools and marshes. The existence of brackish water and generally of water containing alkaline salts which favours decomposition favoured also the development of anthrax. He observed, too, that the use as fodder of the grass or hay of particular meadows or districts was believed to be often the cause of outbreaks. Wilhelm Koch,[15] from consideration of the principal anthrax districts in France (on the banks of the Loire, Oise, Aisne, Saône, the marshy low-lying country of the Gironde, &c.), in Germany (on the banks of the Danube, the swampy sides of the Bavarian Highlands, the valleys of the Elbe, Mulde, Saale, Bode (which are all liable to flood), and elsewhere, concludes that the favouring conditions of soil for the development of the disease as an epizootic are: (1) fairly impervious soils of chalk, marl, or clay; (2) sandy soil, but only when the sand lies in a thin layer on impervious ground and when it is intimately mixed with decomposing animal and vegetable matter; and (3) peaty soils rich in organic and mineral substances, such as prairies, steppes, and moor and marsh land. Height above the level of the sea matters little, but a definite temperature must be reached at which the growth of the bacillus and formation of spores can take place—i.e., between 18° and 40° C. For a typical anthrax district are required only, in addition to the bacillus, a degree of moisture in the soil greater than that of the surrounding country, periodical high temperatures, and profuse vegetation. The moisture must not be so great as to constitute a bog, because the bacillus will not multiply in land thus saturated. As Billings[16] expresses it, "Places liable to be flooded and drying out to a considerable degree in summer and often exposed to the full action of the summer's sun" are those which describe the anthrax district. In America he describes some of the most marked centres as "cups" in high prairie lands, which retain the spring rain but tend to dry out in the summer. The flooding of low-lying lands, followed by drying from great warmth, make certain parts of the valley of the Mississippi markedly anthrax districts. There during the spring and summer of 1895 of a total of 103,507 horses, cattle, sheep, and pigs 6655 were attacked. In the Bavarian Alps in Switzerland Billings further says: "The people know almost to a day how long they dare let cattle graze on the anthrax districts before they must remove them." Factors which must not be left out of consideration, as they form important links in the chain of the creation of anthrax districts, are the insect bird and animal life and the occurrence of dust storms. Marchoux and Salimbeni[17] have shown, for example, the part played by vultures in South America in the spread of anthrax, first by observing them devour the carcasses of animals which had died from the disease and subsequently finding the bacilli in the excreta.

If we consider for a moment the conditions under which the sheep and animals are reared in Asia, especially in Central Asia, the likelihood for occurrence of anthrax among them is apparent. The central plateau of Asia Minor, the home of the Angora goat, is characterised by a climate of severe winter followed by a sultry summer. A prominent feature of this plateau is the existence of numerous fresh and salt water lakes, such as Lake Van, the brackish waters of which have no outlet. Wool is grown in all parts but the quantity produced is dependent on the character and modes of life of the inhabitants. Most is exported from Mesopotamia, where the nomadic inhabitants have no other occupation than to take care of very numerous flocks of sheep migrating with them according to the climate and foraging conditions. These districts are the warmest in Asia Minor and the reason why the wool from the districts of Bagdad and Bassorah is considered of such fine quality is attributed to the fact that the flocks, owing to the mild climate, can pass the winter outside, whereas in the northern mountainous regions the sheep have to be kept under peculiar roofs which are always inadequate to cover the animals which often lie in dirt. Still, the wool from the plains, though of finer quality, contains much more dust than that from the north. Even among the principal family of sheep inhabiting Mesopotamia the character of the wool differs according to the regions whence it comes and various names such as Karadi, Awassi, Mendelli, and Kerkouk are assigned to the qualities. A vast lacustrine region dotted over with lakes or tarns, many of them brackish and with no outlet, or strewn with them like beads on a string, best describes huge districts in Persia, Tibet, Kurdistan, the Kirghiz Steppes, Mongolia, and Northern China, and it is throughout these districts that varieties of the same fat-tailed Persian sheep is found and where the tending of them and of camels, horses, and cattle is the main occupation of the primitive nomadic tribes. Innumerable wild boars haunt the thickets surrounding the salt lakes and swampy delta of the Oxus and Aral.

The number of recorded instances in which the presence of anthrax bacilli has been demonstrated in imported material is not large. This must be because search has not often been made. Andrewes[18] has cultivated bacilli from the dust shaken from a few strands taken at random out of a hydraulically packed bale of China hair weighing five hundredweights. Andrew[19] found them in Siberian hair used for brushmaking in an asylum for the blind in Glasgow and Balfour Stewart[20] in a piece of a Kurachi hide in Liverpool. Other instances are given by Silberschmidt,[21] Gruber,[22] Frank,[23] and Berka[24] in horsehair and by Heim[25] in goat hair. The most important, however, of such experiments are those of Webb and Duncan made at the factory of the former in Worcester. Of eight cases of China mane hair four contained anthrax; of four bales of the same material all were infected, as were also both of two samples of dust taken from large bulk quantities. From these experiments they draw the conclusion that all bales of China mane hair must be regarded as infected. Whether further development of bacilli occurs inside a bale after it has been packed has never been determined.

If then the conditions of soil, temperature, moisture, and decomposing vegetable matter play so prominent a part in the development of outbreaks of anthrax among animals it becomes unnecessary to insist that the contagium must invariably be conveyed directly from animal to animal and from an animal that has died from the disease to man.

[25] Arbeiten aus dem Kaiserlichen Gesundheitsamte, 1901, vol. xviii.

Dirt and sand adhering to the fleeces of healthy Bagdad sheep and Angora goats may contain spores picked up in anthrax districts. In many outbreaks from manipulation of wool, horsehair, and hides no evidence of a fallen fleece or of damaged material is forthcoming. This view is supported by the fact, well known in the trade, that mane hair is considered much more likely to be infected than tail hair inasmuch as the mane hair comes most in contact with the earth. It explains also most readily the remarkable conclusion of Mr. Webb that it would be unsafe to assume that a single bale of horsehair from China was free from risk. The conditions under which animals are herded together in winter "under roofs always inadequate to cover the numerous animals," as is the custom in Kurdistan,[26] or the shelter given to the sheep in caves by the Bedouins in the vilayet of Aleppo might be expected to be much more productive of anthrax once a case occurred than the conditions of soil and temperature described. There is, however, no evidence pointing in this direction.

Several outbreaks of anthrax in animals have been directly traced to spores which have escaped from factories in which raw animal products are dealt with either through pollution of streams or through refuse dust used as manure on fields. Sometimes, however, infection is even more direct. Thus two horses at grass in a field on to which dust from Persian wool used in the manufacture of blankets was blown died from the disease in 1901 in Yorkshire. In a series of outbreaks near Zürich[27] eight out of 22 animals were infected by dust blown from the chimney of a horsehair factory and at least seven other cases were due in one way or another to conditions in this factory. Almost the first recorded outbreak of splenic apoplexy in cattle,[28] as the disease was then called, occurred in the valley of the Yeo in Somerset and the existence of a considerable glove industry at Yeovil suggests that the outbreak had relationship with factory conditions. I mention this outbreak because recently Houston[29] has demonstrated the presence of anthrax (1) in the general effluent from the final catchpit in a hide factory in Yeovil; (2) in the septic tank liquor, the sludge, and the washings of coke from primary and secondary coke beds, and (3) in mud from the banks of the river Yeo and Yeo brook. That the spores of anthrax would, he says, "be swept from the banks in time of flood and carried when present in the mud or river bank down the river to be spread over low-lying land bordering the river hardly admits of any doubt." He guards himself against magnifying the danger thus apparent by saying that "flood water, 'while widening the potentially infective anthrax area,' might affect so wide a separation of the individual spores of anthrax one from the other as to largely remove the element of danger." The fact that there is no increased incidence of anthrax in the hottest season of the year in this country points to the absence of the peculiar and special conditions of temperature and soil which are necessary for the germination of the spores into bacilli and further multiplication of the latter.

On the corporation sewage farm at Kidderminster since 1897, where incidence on the workers from the use of Persian wool during the same period had been high, there have been 11 outbreaks. An outbreak on the sewage farm at Market Harborough in October, 1904, synchronised with the occurrence of three cases of malignant pustule in men employed at a tannery where previously no case had been known to occur. Illustrative outbreaks of a similar nature have been described by Mr. J. Spear,[30] the one traced to washings of Van mohair, manipulation of which had given rise also to cases of malignant pustule in man, and from the refuse sludge from a tannery in London which was used on the farm of the occupier of the factory. Similar outbreaks are reported from Germany[31] and the United States. Thus, in 1901 15 cattle, and in 1900 23 cattle, were believed to have contracted the disease in Marbach on the Neckar by eating grass infected by the water of a stream used in washing foreign hides. At Kirchhain in Hesse-Nassau, an important tanning centre, in 1901 and previous years several outbreaks in animals had been traced to the use of hay from meadows manured with the hair and refuse from tanyards. In 1899 on the Black River, Wisconsin,[32] the distribution of the cases along the river bank for a distance of ten miles below a tannery receiving hides from South America and China indicated the river water as the carrier of the virus. The influence of tanneries in spreading anthrax among the operatives and cattle on pastures watered by streams carrying off the refuse from them was made the subject of inquiry in Pennsylvania during 1897.[33] The deaths of 12 men and 60 head of cattle in that year were attributed to the manipulation of Chinese dry hides in the tanneries of that State. While in some cases, therefore, the association of outbreaks of anthrax in animals with factory and workshop conditions is clear, the evidence when closely examined in this country fails to show that incidence of outbreaks of anthrax in cattle is greatest in counties where industries connected with wool or with raw animal products are mostly carried on. Elsewhere[34] I have shown that the number of outbreaks and the number of cattle attacked in each county worked out as a proportion on the number of cattle in each of the counties over a period of five years, negatives so far as can be done by this means, any close association. Indeed, incidence on animals appears to be greatest in counties where danger from factory conditions appears most remote, as, for example, in Cornwall, Westmorland, Northumberland, Hertford, Aberdeen, Banff, Elgin, and Haddington. Incidence of anthrax on animals is twice as great in Scotland as it is in England, yet incidence on the human subject from wool is negligible in Scotland as compared with England. No doubt the direct influence of a particular factory in causing anthrax in animals operates over an extremely limited area, but the use which it is well known is made of refuse dust from wool and horsehair factories as manure is an unknown quantity and may be the cause of many outbreaks the origin of which cannot be traced. Most cases are rightly attributed to the consumption by cattle of infected fodder either from direct grazing on fields where previously cattle had died from the disease, or from grass which had been cut from places where animals have died, or where the carcasses have been buried at an insufficient depth.

As showing the probable relation of the bacillus to the soil I would cite as instructive the tracing of outbreaks in 1903 and 1902[35] to the feeding of cattle on turnips grown near the place where an animal suffering from anthrax had been [illegible] in the digging up of [illegible] f the death of six [illegible] from consumption [illegible] s of anthrax must have been attached, as only the six oxen thus fed succumbed. But recital of such cases does not explain sufficiently all the outbreaks in animals, particularly those erratic instances occurring on farms hitherto free from the disease. To account for these McFadyean[56] suggests two possible sources: (1) artificial manure and (2) imported feeding stuffs. Against the view that artificial manure can be the cause he states "the erratic way in which outbreaks occur throughout the country apparently quite unconnected with the more or less liberal employment of artificial manure." In analysing 39 consecutive outbreaks, in 29 of which there was no previous history of anthrax on the farm, he found that in 26 of the 39 outbreaks the animals were receiving a diet into which artificial food in different forms entered. He says: "The circumstances connected with the series of outbreaks deepen the suspicion which already existed that a considerable number of cases of the disease in this country have an extraneous source of infection and that the vehicle of infection is not infrequently some artificial food stuff of which the raw material is derived from a foreign country." In one outbreak amongst cattle which caused the death of six valuable shorthorns he isolated the bacillus from linseed cake and in this instance as soon as the linseed meal was stopped the outbreak ceased. In another outbreak among horses in London similarly the bacillus was isolated from the oats. Of the outbreaks in Germany in 1903 Russian bran was believed to have been the cause in several instances. In 1902 fodder consisting of bran, barley or hay from Russia is cited as having been believed to be the cause of the outbreaks in seven instances. In 1901, in addition to fodder imported from Russia, reference is made to two farms believed to have been infected from fodder grown in the tropics. This view makes intelligible the source of infection in the case of a corndealer, a person unloading corn in a warehouse, and a person carrying sacks of potatoes mentioned at the beginning of this lecture. If the soil under certain conditions is recognised as a suitable medium for the growth of the bacillus it is no longer necessary always to seek for the material cause in raw animal products alone.

ON

THE PHYSIOLOGY AND TREATMENT OF SURGICAL SHOCK AND COLLAPSE.

Delivered before the Royal College of Surgeons of England on March 6th, 8th, and 10th, 1905,

BY J. P. LOCKHART MUMMERY, M.B.,
B.C. CANTAB., F.R.C.S. ENG.,
HUNTERIAN PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS OF ENGLAND; HONORARY SURGEON TO KING EDWARD VII.'S HOSPITAL, ETC.

LECTURE I.

Delivered on March 6th.

MR. PRESIDENT AND GENTLEMEN,—In most of the surgical treatises of the seventeenth and eighteenth centuries shock, if it is mentioned at all, is only described as a complication of gunshot injuries and it is attributed to the commotion or agitation communicated to the body by the bullet. Peter Lowe, a Scotchman, writing in 1612, describes syncope as a "sudden fall and decay of the whole forces of the body," and he gives as the cause of it "intemperature of the noble parts, vehement passion of the spirits, and anything which may destroy the vital spirit." The shock following gunshot injuries is attributed by him to a loss of vital heat or spirit. Le Dran, in 1737, describes shock as due to the agitation set up in the body by the bullet. Travers, writing in 1826, attributes it to a functional concussion, Groeningen, in 1835, describes shock as due to the vibratory effect of the injury. This commotion theory of shock seems to have been the most usually accepted one up to a comparatively recent date. Dupuytren attributed shock to a hæmorrhage of nerve energy. Shock has often been supposed to be due to an effect upon the heart caused by the injury either of the nature of exhaustion of that organ or of the centres controlling it. In almost all text-books on surgery there is a chapter on shock and its treatment, but if one looks back at the older text-books one cannot help being struck by the fact that there is very little difference between the way in which the subject is treated in the older books and in the more modern ones. With but few exceptions we find that the cause is mentioned as doubtful, or unknown, or is wrongly attributed to cardiac exhaustion, and the methods of treatment are based with but few exceptions upon empirical grounds or upon false ideas of the physiological causes.

The two great dangers of any big surgical operation are sepsis and shock. Thanks to the modern aseptic methods of performing operations sepsis has been practically eliminated as a source of danger and the most extensive and heroic operation can now be performed with almost complete safety as regards any fear of subsequent septic infection. But we still have to contend with shock and our aim should be to eliminate that also as thoroughly and effectually as we have eliminated sepsis. Could we be certain of preventing shock or of effectually treating it much would have been done to render surgical operations free from danger and we should be able to reduce the mortality of many operative procedures. Much has already been done by improvement in the methods of administering anæsthetics, by improved methods of operating, by saline infusion, and other allied methods to get rid of this source of danger. But much still remains to be done before shock can be said to have ceased to be a danger in the more severe surgical procedures, especially when these involve interference with the abdomen or its contents.

The study of the causation of shock is not a pathological study and pathology can teach us little or nothing in regard to it. It is a study in physiology, or rather in morbid physiology, and to understand shock and its production it is necessary to understand the physiology of the circulation and more especially of the blood pressure. If we consider the circulation as a great hydraulic system we cannot help being astonished at the way in which the pressure is maintained at or near a uniform level. In spite of the complexity of the circulatory system of man the blood pressure is maintained within a few degrees of the normal range even under extreme variations in outside pressure. In a normal healthy individual the variations in the blood pressure which follow changes from the standing to the sitting position or violent exercise or changes in atmospheric pressure are very slight. Just, however, as is the case with the thermic mechanism, so with the circulation once the individual is in an abnormal condition from disease or injury great changes in the pressure are liable to follow comparatively slight effects. The circulation of the body may be looked upon as a vast hydraulic system of infinite complexity and under the most complete control and these conditions as the results of a breakdown in the system. Ever since Harvey's great discovery the circulation of the blood has been the subject of much study. Till comparatively recently, however, but little has been known about the hydraulics of the circulation. Investigation has chiefly been confined to observations upon the pulse-rate and although the arterial tension has always been considered important and much has been learnt by its careful study by experienced clinicians, no great advance has been possible until the discovery of a suitable instrument by means of which the blood pressure can be measured accurately under normal and abnormal conditions. There are two ways in which the physiology of the circulation has been studied: (1) by experiments on animals; and (2) by clinical observations with the aid of suitable instruments for recording the blood pressure.

1. *Experiments upon animals.*—A very large number of most carefully conducted experimental observations have been carried out upon animals for the purpose of investigating this subject. There cannot, I think, be any doubt about the accuracy of these experiments as they have been amply repeated and confirmed by control experiments. There is now a very large amount of experimental data on which a more or less exact knowledge of the physiology of the condition known as shock can be founded. The most valuable work that has recently been done upon this subject is that of C. S. Sherrington, Louis Cobbet and Roy, and G. W. Crile. Almost the whole of the experimental data have been obtained by experiments upon dogs. One often hears it said that the results obtained by experiments upon dogs are not a fair criterion of the same conditions in man. And this argument is often used against the adoption of results obtained in the lower animals by experiment in the treatment of abnormal conditions or disease in man. There is, of course, a certain amount to be said for this argument but since it is impossible for experiments to be performed upon man experiments upon animals afford the only way of ascertaining the physiological conditions of the circulation in health and disease. I think when by experiments upon animals we find certain definite results follow upon certain definite causes and from these results are able to deduce a working theory which is adaptable to man, we should consider it carefully. In the case of shock the facts are very conclusive. By a large series of experiments upon dogs the physiology of shock has been most carefully worked out and the most important factors in the causation of that condition have been accurately determined. Assuming that the physiological causes of shock so worked out are also correct in man we find that all the clinical facts are compatible with that assumption and that if careful observations of the blood pressure in a patient suffering from different degrees of shock are made the results are the same as those in the experiments on animals. And further, still assuming the

theory to be correct, we find that if we treat patients suffering from shock by methods founded upon the known physiological cause of that condition we are able to modify or to arrest the shock. When these conditions are fulfilled I think we are justified in saying that we have as much proof of the causes and physiology of shock in man as is necessary. In the case of shock all these methods of [illegible] ed out and have been found to [illegible] physiology of shock cannot be [illegible] main factors in its causation are known and have been sufficiently proved to allow of their being taken as a foundation for methods of rational treatment.

2. *Methods of estimating the blood pressure in man.*—Numerous instruments have been invented for the purpose of making clinical observations of the blood pressure. The earlier forms of apparatus, such as Hurthle's, where the arm was inclosed in a glass cylinder filled with fluid, are only suitable for laboratory work. Potain's and Hoepfle's instruments, though designed for clinical work, were too inaccurate to be of much value. These instruments were designed to estimate the pressure necessary to obliterate the pulse. Oliver's hæmadynamometer is not a very accurate instrument except in the hands of its inventor or a specially skilled observer. Gaertner's tonometer is too complicated for ordinary use and has too large a margin of error. The most practical of these instruments are Oliver's hæmadynamometer and the Hill-Barnard instrument. The chief objection to them is that they both record diastolic pressure and that to obtain a reading with them it is necessary to measure the point at which a needle or the upper surface of [illegible] As the excursion [illegible] difficult to obtain [illegible] d there is thus a large margin of error. In the hands of skilled observers they no doubt give very fairly accurate results but in the hands of others they are apt to be very untrustworthy. Another objection to this type of instrument is that it takes some little time to obtain a reading of the blood pressure. For an instrument to be of much clinical value it is necessary that it should be able to be used by anyone of average intelligence without any special training in its use and that there should be only a small margin of error. By far the most satisfactory instrument is the Riva-Rocci sphygmometer in one or other of its different forms. This consists of a mercurial manometer connected by rubber tubing to an inflatable rubber armlet which fits round the arm above the elbow. Connected to the tubing by a T-piece is a rubber bellows by means of which the pressure within the armlet can be increased. It estimates the pressure, acting at right angles to the artery, which is necessary to obliterate the pulse at the wrist on the peripheral side of the cuff or armlet. This pressure is the maximum systolic pressure. This is a thoroughly practical and useful instrument; it is simple in construction, it gives a positive reading within one or two millimetres of mercury, no special skill is needed to use it, and there are no springs to become worn and alter its accuracy. The Riva-Rocci sphygmometer was first brought into general use by Dr. Harvey Cushing. The great advantage of this instrument over all previous ones is that it can be very easily used and is simple in construction. Any nurse can take a reading with it and both at St. George's Hospital and the North-Eastern Hospital blood pressure charts have been kept for me by the nurses for some time and the instrument has proved perfectly suitable for ordinary routine clinical work. A reading with it can be made by anyone who has been trained to feel the pulse. The instrument records systolic pressure and the objection has been raised that this may result in error and that the mean arterial pressure ought to be taken. The mean arterial pressure would certainly be better, but it is not at present possible to get any instrument with which the mean arterial pressure can be recorded that is in any way suitable for practical use. The Riva-Rocci instrument can be used for ascertaining both the systolic and diastolic pressures (from which the mean pressure can easily be calculated) by using rigid tubes to connect the different parts of the apparatus. The position of maximum pulsation of the mercury column will then give the diastolic pressure. A portable Riva-Rocci instrument on this principle has been invented by Dr. Zaneway of New York. Zaneway's instrument has heavy tubing and is arranged to allow the diastolic as well as the systolic pressure to be ascertained. Stanton's instrument is also similarly constructed. Erlanger has invented a recording sphygmomanometer, with which it is possible to obtain absolutely accurate readings of both the systolic and diastolic pressures. This is by far the most accurate instrument but it is far too complicated and cumbersome for clinical use.

There are now several patterns of the Riva-Rocci sphygmometer. The best are those in which the cuff or armlet is at least four inches broad and in which the calibre of the manometer is not too narrow. For ordinary hospital use the patterns with a straight, upright manometer tube are the best as the reading is direct and no calculation is necessary to obtain the blood pressure in millimetres of mercury; also the mercury is less easily spilled than in the instruments fitted with a U-shaped manometer. In all the instruments which measure the blood pressure by estimating the point at which maximum pulsation occurs it is assumed that this point corresponds to the diastolic pressure. It seems almost certain, however, that it is not the diastolic pressure which is thus estimated nor yet the mean pressure. And we do not at present know what relation this so-called diastolic pressure bears to the real arterial pressure. We do know, however, that we can accurately estimate the systolic pressure by means of the Riva-Rocci type of instrument, and it is better, therefore, to record the systolic pressure only and not at present to attempt recording the mean pressure.

The blood pressure charts illustrating these lectures are compiled almost entirely from records taken with the Riva-Rocci instrument of the type shown and using a broad armlet. A source of error in the use of this instrument is that such conditions as rigid muscles, œdema of the tissue, or rigid arterial walls as in arterio-sclerosis will, by offering greater resistance to the compression of the pulse, lead to too high pressures being recorded. As a matter of fact, the error is not great except when marked arterio-sclerosis exists and for the present purpose this objection may be allowed to pass, since it is the variations in arterial pressure in a given case rather than the comparative records of blood pressure in different patients that are of importance. Its greatest value is as a test of therapeutic measures, since not only does it show the exact effect upon the blood pressure of the administration of a certain drug or procedure but it enables us to ascertain with accuracy the duration of this action. As showing the value of certain methods of treatment for conditions such as shock and collapse it is of the very greatest value and it has put an entirely new complexion upon the use of stimulants.

In using the Riva-Rocci sphygmometer the patient should always be in a horizontal position. The armlet is then adjusted round the arm above the elbow and whenever possible I use the left arm so as to keep the conditions as comparable as possible. The armlet should fit closely and should be strapped on. The instrument and inflator are then connected and with the left hand feeling the pulse air is pumped slowly into [illegible] gradually increased until [illegible] the pressure at which th [illegible] meter and then the pressure is allowed to fall slowly and the exact point at which the pulse at the wrist returns is noticed. This pressure or the mean between it and the first reading is taken as the blood pressure. In order to avoid error from respiration affecting the blood pressure as far as possible I always take a second pair of observations at once in the same way and take the mean of the four readings. It takes about 30 seconds, as a rule, to take a record of the blood pressure when one is used to the apparatus. In taking blood pressure charts of operations I always, if possible, obtained two or three observations of the patient's blood pressure previously to the commencement of the administration of the anæsthetic. During the operation observations were generally taken every five minutes or oftener if it seemed advisable. No observations were taken while anæsthesia was being induced as the variations were considerable but unimportant.

The accuracy of the instrument has been tested by observations on the cadaver, the pressure (artificially produced) within the vessel being known. It was found that the Riva-Rocci instrument gave accurate results and the resistance of the tissues caused but slight differences. By the kindness of Dr. A. D. Waller, the director of physiology at the Imperial Institute, and Dr. W. L. Symes I have been able to test the accuracy of the Riva-Rocci sphygmometer upon animals by actual comparison with a mercurial manometer connected to a cannula in one of the main arteries. Three experiments were made upon different animals. In the first experiment a glass cannula connected to an ordinary mercurial manometer was tied into the right femoral artery and the armlet of the Riva-Rocci sphygmometer was fastened round the left thigh of the animal. In the first two animals used it was found very difficult to feel the pulse and in order to do so the artery had to be exposed in the popliteal space and directly palpated. The readings were as follows: Riva-Rocci sphygmometer, 108, 107, 107; Hg manometer, 110, 106, 106. In the second experiment the same procedure was followed. The readings were: Riva-Rocci sphygmometer, 65, 65; Hg manometer, 64, 64. In the third experiment a medium-sized dog was used and it was possible to feel the pulsation of the posterior tibial artery through the skin without exposing the vessel. The results obtained were as follows: blood pressure in right femoral with Hg manometer connected to the artery, 106, 108, 108, 110, 86; blood pressure in the left femoral obtained by Riva-Rocci sphygmometer, 118, 107, 110, 110, 84. The error of the first reading was accounted for by the armlet not being adjusted properly. These experiments show that the instrument works with quite a negligible degree of error and that the readings obtained with it may be taken as accurately representing the blood pressure in the artery compressed by the armlet. The resistance of the tissues overlying the artery did not appear in these experiments to make any difference to the readings, as the blood pressure observed with the sphygmometer was sometimes higher and sometimes lower than the real blood pressure, and what error there was appears to have been due to the personal error of the observer and not to any fault in the instrument.

Variations in the blood pressure in health.—Gravity plays a very important part in the height of the blood pressure in man and considerable variations occur in the pressure as estimated by observations on the brachial artery in different positions of the body. Dr. Stephens made a series of observations upon 22 male medical students of an average degree of health in different positions. The median or average pressure in the supine position was 156·4 millimetres of mercury and the pulse-rate was 68·7. This is the position in which the blood pressure in the body as a whole is maintained at a high level with the least difficulty as shown by the low pulse-rate as compared with any other position. In the head-down position the average pressure is 165·6 and the pulse-rate 65·8. In the standing position the average pressure is 131·0. In the lateral positions there is a very marked difference on the two sides which is accounted for partly by the effect of gravity and partly by the relation of the heart and great vessels to the position. The average pressure is 133·8 and the pulse-rate 68·6. In the right lateral position the blood pressure is 1·5 millimetres of mercury greater than in the left. The difference in the pressures in the left and right brachials is very marked, varying least in the supine and head-down positions, though in some cases it was as much as 20 millimetres of mercury. It is not possible or advisable, considering the great variations in blood pressure in different positions of the body and on the two sides, to fix any normal pressure. The normal pressure may be taken as being between 120 and 140 millimetres of mercury for a young adult. The most usually adopted normal pressure is 130 millimetres of mercury. In my own observations I have found 130 to be the most common normal pressure for a healthy adult of middle age. Mental conditions, such as excitement, fear, &c., cause temporary alterations in blood pressure. A series of observations made in America on the inmates of an orphan asylum demonstrated frequent slight variations in the blood pressure of different and of the same individuals. The ingestion of food causes a marked alteration in general blood pressure. A rise in pressure first occurs after a meal, to be followed by a fall which reaches its minimum in a few hours. This fall in pressure in the brachial artery is due to a corresponding rise in the splanchnic blood pressure due to the flushing of the intestines with blood.

Under abnormal conditions.—Variations in pressure outside the body cause alterations in the blood pressure but the vaso-motor centre is capable of compensating the pressure to an extraordinary extent. Thus in the sinking of caissons and building of tube railways the workmen often work in compressed air under very high pressures. It has been found that with ordinary care men are able to withstand pressure as high as 40 pounds to the square inch, an astonishingly high pressure when one remembers what a delicate mechanism the circulation is. Similarly it has been found in mountain and balloon ascents that very low external pressure can also be sustained without serious results and with comparatively slight alterations in the blood pressure. Potain made observations of his blood pressure during balloon ascents. In diseased states great variations in blood pressure often occur. Inflammatory conditions, especially if they affect the peritoneal cavity, cause a considerable rise in the blood pressure. In fact, perforation of the intestines or stomach and peritonitis have been diagnosed by observations upon the blood pressure. Curiously enough, organic cardiac disease has, as a rule, but little effect upon the general blood pressure. In fevers a marked rise in blood pressure is generally noticed at first but if the fever is long continued a decided fall subsequently occurs. A decided fall in blood pressure is seen during the critical stage of almost all fevers. Variations in the blood pressure occur in a great variety of abnormal and diseased conditions and it seems not improbable that in future these variations will prove to be of as much clinical importance as the variations in body temperature now are. A considerable fall in the arterial blood pressure usually results in one of three abnormal conditions or morbid physiological states—syncope, shock, or collapse. To study any one of these conditions necessitates a study of all three, since the physiological factors in each are similar. I shall start by defining these three conditions according to their physiological causes in order to prevent, if possible, any misconception in terms and I shall then proceed to give the reasons for these physiological definitions. Syncope may be defined as a sudden cessation of the cerebral circulation or cerebral anæmia. Shock may be defined as the condition resulting from a fall in general blood pressure due to exhaustion of the vaso-motor centres. Collapse may be defined as the condition resulting from a fall in general blood pressure due to inhibition of the vaso-motor centres or a loss of circulating fluid in the vessels.

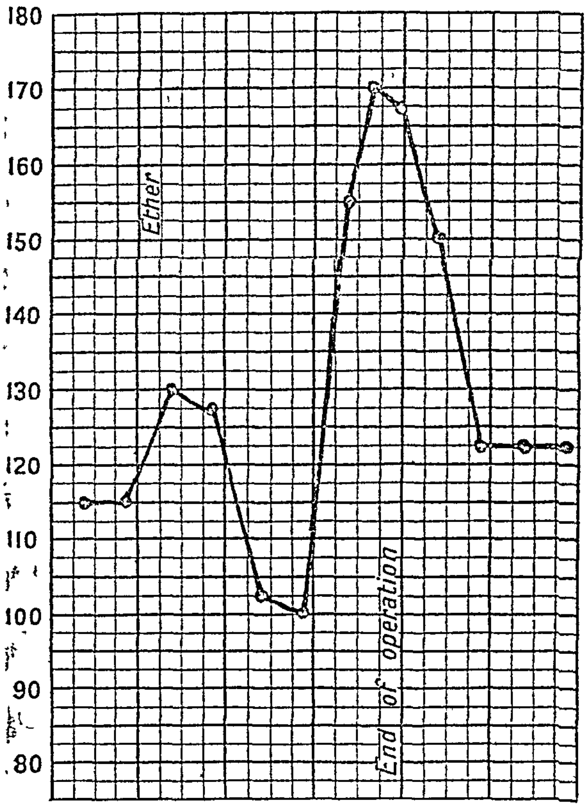
Syncope.—This is a condition that appears to be peculiar to human beings. It has been shown by Mr. Leonard E. Hill that if a tame hutch rabbit is suspended by the ears it soon passes into a condition of syncope and if not put down dies. A wild rabbit, however, will stand being placed in a vertical position for a considerable time. If, however, the wild animal be chloralised suspension soon results in syncope and death; if when the animal is in this condition a tight abdominal binder be affixed the animal recovers and further suspension has no effect. The most probable reason why syncope or fainting is peculiar to the human subject is that the nervous system of man is much more highly developed and more delicately balanced than is the case in animals and also that man owing to his upright position has his circulation more under the influence of gravity and so has to depend almost entirely upon his nervous system for the proper maintenance of his cerebral circulation. In man any sudden disturbance of the higher vaso-motor centres which puts them even momentarily into abeyance allows gravity to act upon the circulation and as we should expect is followed by a sudden fall in the cerebral blood pressure, resulting in anæmia of the brain and syncope. In animals, however, we should not expect this to happen as their horizontal position does not give gravity the same advantage in respect of their cerebral circulation. That many other causes besides the fall in cerebral blood pressure contribute towards the condition we call syncope there can be little doubt; all the higher centres must be more or less affected, either primarily or secondarily, but the primary factor in the causation of syncope is the sudden stoppage of the cerebral circulation resulting from a fall in general blood pressure. It appears fairly certain from the experiments of Hill and Gulland that, whether there are vaso-motor nerves to the pial vessels or not, the vaso-motor centre does not exert any influence over the cerebral circulation such as is the case in other organs; so that the anæmia of the brain which occurs in syncope is entirely attributable to the fall in blood pressure in the general circulation and is not the result of any local contraction of the cephalic blood-vessels. It seems probable that the condition of syncope is due to a cessation of function of the cortical centres of the cerebral hemispheres, as loss of consciousness is the most marked symptom of the condition. A certain amount of rigidity is commonly seen in syncope and sometimes this may amount to a spastic condition. It would be extremely difficult, if not altogether impossible, to collect any statistics to show in what percentage of all cases of syncope there is definite spasticity of the limb and trunk muscles. Cases of syncope occur quite unexpectedly as a rule and. no medical man is at hand to observe whether the patient is rigid or not during the attack. Most medical men, however, who have been questioned on this subject admit that marked rigidity is often present. I have myself frequently observed marked spasticity in patients who have fainted and believe that a certain amount of spasm invariably accompanies a genuine attack of syncope. Professor Sherrington was the first to describe a condition which he has called decerebrate rigidity and which is a form of persistent extensor spasm. He found that after ablation of the cerebral hemispheres in an animal this condition of decerebrate rigidity comes on, either immediately or after the lapse of several minutes; the condition is a spastic one of the limb and neck muscles, the whole animal being more or less rigid with the exception of the digits. This spastic condition lasts for several hours or even days. It can be inhibited by peripheral stimulation of the skin or any of the afferent nerves or cortical centres. This decerebrate rigidity which occurs in animals after removal of the cerebral hemispheres probably has some relation with the spastic condition seen in human beings during an attack of syncope, only that in the latter case it is due to sudden alteration in intracranial pressure. That sudden anæmia of the brain from cutting off of the blood-supply will give rise to syncope there does not seem to be any doubt; obliteration of the carotid arteries in man is followed by dizziness, loss of consciousness, and often by spasm. It is interesting to notice in this connexion that some people are able to produce syncope at will by compressing their carotids, and that this method of voluntarily causing syncope is used as a form of magic to impress the ignorant among the natives of Burma and Java. It is known as Javanese anæsthesia and is undoubtedly only syncope from sudden cerebral anæmia. It was the knowledge of this physiological fact that enabled the garroters to render their victims unconscious while their pockets were rifled. Ligature of both the carotid and vertebral arteries almost simultaneously has been performed in animals many times and is found to result in loss of consciousness and voluntary movement followed in a few minutes by clonic spasms of the neck and trunk muscles The cause of syncope is a sudden cessation of the cerebral circulation or cerebral anæmia resulting from a sudden fall in cerebral blood pressure. This sudden fall in blood pressure may be produced in a great many ways, many of which are difficult to explain. It may follow upon sudden mental impressions, especially in individuals the tone of whose central nervous system is below normal; it may follow sudden loss of fluid from the circulation; it may follow violent stimuli to afferent nerves, as in blows upon the testicle or in the splanchnic area; it may follow compression of the carotids; it may result from the effects of gravity alone, as in persons who have been long in the recumbent position and who faint upon first assuming an erect position; and it may result from several other conditions where the cause is less obvious.

In syncope, therefore, the cerebral effects produced are caused by the sudden stoppage of the cerebral circulation, but it seems probable that this is not due to cutting off of the blood-supply to the brain tissue, as if such were the case similar cerebral effects ought to occur in conditions of shock and other conditions where anæmia of the brain is produced, but we find that so long as the anæmia of the brain is produced slowly no cerebral effects result. Also we know from experiments that the brain can remain functional on a very small blood-supply. The cerebral effects that occur in syncope therefore are not to be looked for in the effect on the brain tissue caused by the lack of blood-supply. The cause of the cerebral effects, such as loss of consciousness and spasm which result from sudden cerebral anæmia, is probably mechanical from the sudden change of tension in the cranial cavity as a whole. Sudden lowering of the cerebral arterial pressure will tend to cause a vacuum in the cranial cavity as the amount of blood in the cavity tends to be diminished suddenly and the amount of cerebro-spinal fluid immediately available to take its place is very small and increase in the quantity of the latter fluid by the transudation of lymph must of necessity be slow. Consequently when the blood pressure in the cranial cavity is suddenly diminished a great alteration in the pressure on the brain tends to take place. When the cranial blood pressure is slowly reduced, however, as is the case in shock and collapse, no such sudden alteration in intracranial tension occurs and there is time for cerebro-spinal fluid to take the place of any deficiency of blood in the cerebral vessels. No alteration therefore in the intracranial pressure need occur and, as a matter of fact, we do not find loss of consciousness and spasticity associated with the conditions of shock and collapse. The physiological law which has been called the Monro-Kellie doctrine states that the quantity of blood in the brain must be the same at all times and that it is not the volume of blood but the rate of flow through the vessels that is altered by changes in the general blood pressure. I think, however, that this law is only true for sudden alterations in blood pressure and that the explanation just given why the cerebral effects seen in syncope do not occur in shock is correct.

Physiology of shock.—The essential factor in the production of the condition which we know as shock is a steady fall in general blood pressure. This fall in blood pressure results from exhaustion or fatigue of the vaso-motor centres. That it is not due to structural changes is evident from the fact that no lesions are found in persons dying from shock and that when recovery takes place it is complete. If we take the experimental evidence we find that shock may be produced in two main ways: (1) by injury to important afferent nerve paths; and (2) by exposure or injury of the abdominal viscera

Shock produced by injury to important afferent nerve paths.—In Crile's experiments the animals were anæsthetised and the general blood pressure was estimated by means of a mercury manometer tied into the carotid artery. He found that if the animals were subjected to severe and repeated traumatism involving important nerve paths after a time there was marked fall in the general blood pressure which was steadily progressive, the animal passing into the condition of shock after a certain minimum pressure was reached. If the traumatism was sufficiently severe or was continued the blood pressure eventually fell to nothing and the animal died with the usual symptoms of shock. The fall in blood pressure was slow at first but towards the end was often rapid. By connecting another manometer with the portal vessels he was able to prove that the portal blood pressure rose while the systemic pressure was falling. This proves that the essential cause in the fall in the systemic pressure is dilatation of the vessels of the splanchnic area and consequent loss of blood from the systemic circulation into that area. That this fall in blood pressure is not due to cardiac exhaustion or, indeed, any cardiac condition was proved by the fact that shock could be produced just as readily after the cardiac branches of the stellate ganglion had been divided or the cardiac inhibitory apparatus had been cut out by section of the vagi or the injection of atropine. This clearly shows that the heart has no part in the production of shock and changes in the pulse which occur in shock are entirely secondary to the changes in blood pressure. Crile's experiments clearly show that shock resulting from severe amputations or other traumatisms of the extremities is solely due (hæmorrhage excluded) to the injury to the nerves of the part and is in direct proportion to the nerve-supply. Thus shock is more readily produced by crushing the paw of an animal than by amputation of the limb high up. This was further proved by the fact that if previously to injuring the limb the main afferent nerve trunks were cocainised so as to prevent afferent nerve impulses from reaching the brain and spinal cord no fall in blood pressure resulted and no shock was produced, however severe the traumatism. Crile found that the readiness with which shock was produced varied considerably in different animals and also with injury to different nerve paths. Thus injury to the genital organs produced shock much more rapidly than injury to the paw. Stimulation of any afferent nerve tends to cause an alteration in the blood pressure. The most usual result seen from stimulating a nerve is a rise in blood pressure. This is very easily seen during experiments on animals and is frequently seen clinically during operations if a record of the blood pressure is kept by means of a sphygmometer. The incision of the skin usually results in a marked rise in the blood pressure. Dilatation of the sphincter ani causes a very marked rise in the blood pressure (see Fig. 1). A similar result is also seen during dilatation of the os uteri (see Fig. 2). Stretching a nerve such as the sciatic for sciatica causes a very great rise in blood pressure and the first effect of almost any traumatism is to produce a rise in blood pressure. Recent observations, and especially those at Howell's laboratory, seem to show that in every mixed nerve there exist definite nerve fibres the central stimulation of which produces a rise in blood pressure through their action on the vaso-motor centre. These fibres have been called "pressor fibres." There are also other fibres the central stimulation of which produces in a similar manner lowering of the blood pressure; these fibres have been called "depressor fibres." Both pressor and depressor fibres are found in all large mixed nerves. The pressor fibres are those which most readily respond to stimulation, as they are also the first to become exhausted. Howell has demonstrated that if cold is applied locally to a mixed nerve, pressor effects—that is to say, a rise in blood pressure—can no longer be elicited by stimulation but depressor effects can still be produced. Hunt, working along the same lines, has shown that certain forms and kinds of stimulus will affect depressor fibres only and consequently such stimuli produce a fall in pressure only without any previous rise. The experiments of these observers seem to show that the first effect of stimulation of a mixed nerve, whether from injury or other cause, is to produce a pressor effect—that is to say, a rise in blood pressure—but on repetition of the stimulus, or if it be of a certain degree of severity, a point is reached where depressor effects alone follow stimulation and a fall in blood pressure results. This may be seen clinically during surgical operations. I have several times noticed that when a severe operation has been going on for some time and the first signs of shock have shown themselves by a fall in the blood pressure, injury to a nerve from traction upon it, or from cutting it, or stimulation from enlarging the incision, has produced not a rise in the blood pressure as is usually the case but a definite and sudden fall to a lower level, showing that a depressor effect alone has been produced. These nerve impulses, reaching the vaso-motor centre by the afferent nerves from the site of operation or injury, are undoubtedly the main cause in the production of shock from injury or operation. This is proved beyond question by the fact that blocking these nerve impulses by cocainising the nerve trunks of the part prevents any alterations in the blood pressure resulting from injury or operation to the parts distal to that at which the nerves are cocainised.

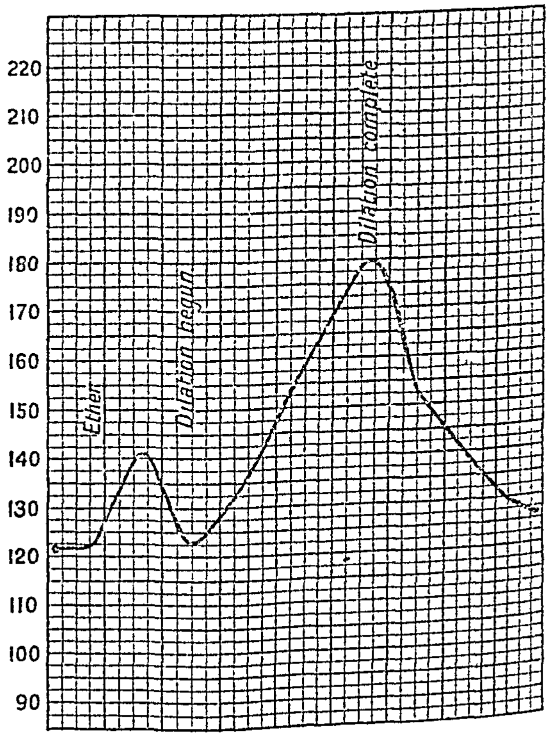
FIG. 1.



Shock produced by exposure or injury of the abdominal viscera.—If an animal's abdomen was opened and the intestines freely exposed it was noticed that after a variable interval a marked fall in general blood pressure took place accompanied by vascular dilatation of the whole of the splanchnic area and if the exposure were continued the animal was eventually reduced to a profound degree of shock. This effect did not occur immediately but was sooner or later certain and was steadily progressive. Injury or manipulation of the intestines increased the effect in a marked manner and hastened the onset of profound shock. Mere exposure of the intestines, however, without any more injury than that necessary to open the abdomen is sufficient to produce shock. The fall in blood pressure after exposure of the abdominal viscera is due to dilatation of the splanchnic vessels. This could be seen to take place in these experiments and has, moreover, been frequently observed clinically in man. Further, if the arteries supplying the splanchnic area were clamped before opening the abdomen no amount of exposure or manipulation of the intestines gave rise to a fall in the blood pressure and no shock resulted. This seems to show that one of the most important factors in the production of shock is the condition of the splanchnic vessels. The vessels of the splanchnic area may be called the key of the blood pressure. It is owing to the control of this large vascular area by the vaso-motor centres through the splanchnic nerves that the blood pressure is kept at a constant level under varying conditions of the circulation. If it were not for the existence of this great vascular reservoir the distribution of the blood in different portions of the body could not be altered to any appreciable extent without causing tremendous variations in the systemic blood pressure.

Another very important series of experiments are those of Professor Sherrington and Dr. S. Monckton Copeman in which they have shown that operations upon a healthy animal are followed by a loss of fluid from the blood. After the operation has proceeded for some time the specific gravity of the blood commences to rise. This increase in the specific gravity tends to occur earlier but is prevented by absorption of fluid from the tissues and it is when this source has been exhausted that the rise in specific gravity takes place. In one of Professor Sherrington's experiments the specific gravity of the blood rose from 1·054 to 1·062 in 15 minutes during an operation for intestinal anastomosis in a healthy dog. This increase in the specific gravity was found to last for several days after the operation and then slowly to pass off. These observations upon animals have been confirmed by testing the specific gravity of the blood of patients before, during, and after operations both by Professor Sherrington and others. Increase in the specific gravity is most marked after operations involving exposure of the peritoneum and in cases involving extensive denudation of tissue. This increase in the specific

FIG. 2.

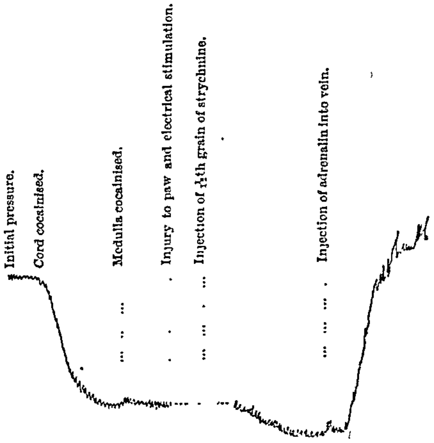


gravity of the blood is most marked after opening the abdomen and exposing the intestines and the effect is increased by injury to the intestines. It is also well marked after burning or scalding the skin. This at once suggests that the increase in specific gravity is due to evaporation from a tissue surface uncovered or denuded of the skin which should ordinarily protect it. There does not, however, appear at present to be sufficient evidence to prove that this is the case. That this factor is an important one in the production of shock in some cases the [illegible] of [illegible] me [illegible] cir [illegible] which is such a common feature after most abdominal operations. From the aspect of treatment it is of considerable importance, as it has been supposed that the transfusion of saline solution so lowered the specific gravity of the blood that it was prevented from being beneficial in the treatment of shock except when employed in small quantities. This is, however, not the case, as a large quantity of saline solution has to be injected before the specific gravity will even come down to the normal and, indeed, it was found in the experiments that although the specific gravity could be reduced to the normal by transfusion it rapidly increased again if the exposure of the peritoneum was continued. In some of the *observations made upon patients during prolonged abdominal* sections the rise was as much as five or even seven degrees. Cobbett and Roy somewhat earlier had carried out a similar series of experiments in which they showed that the shock resulting from prolonged abdominal operations was accompanied by a marked increase in the specific gravity of the [illegible] k that it [illegible] Arguing [illegible] tration of the abdominal operations to the collapse of cholera in which a similar inspissation of the blood is found to occur. [illegible] ge in [illegible] the [illegible] Dr. W. S. Lazarus-Barlow has shown that if the volume of blood in the body is increased by bandaging the extremities there is an outpouring of fluid from the blood into the tissues and the specific gravity of the tissues is *lowered*. After a few hours, however, the normal equilibrium between the blood and the tissues is re-established again. If, then, the bandages are removed the volume of blood in the body is decreased and there is a flow of fluid from the tissues into the blood so that the specific gravity of the tissues is *increased*. This seems to show that when there is a demand for a larger volume of blood the tissues give up fluid to the blood to make up the deficiency and when there is occasion for a less volume of blood in the body the reverse condition occurs. From this it seems probable that the alterations in the specific gravity of the blood which occur in shock are the result of the fall in the blood pressure.

Another phenomenon of importance which has been observed in shock was first noticed by John Hunter while bleeding a patient for syncope. He noticed that the blood which flowed from the vein was bright red instead of being blue. This arterial hue of the blood in the veins during conditions of greatly lowered blood pressure has been noticed by numerous different observers and has been attributed to very different causes. One obvious explanation is that owing to the vaso-dilatation which is the cause of the fall *in blood pressure the blood is able to get through fro* [illegible] arteries into the veins more easily than normal and [illegible] sequently does not lose its oxygen. Brown-Séquard [illegible] that this condition of an arterial hue of the venous blood was present in animals suddenly killed by electrical stimulation of the vagi, and he says that arterial contraction accompanied the condition. He therefore argues that this condition of arterial blood in the veins must be due to an arrest of all metabolic processes. He noticed the same condition in shock experimentally produced. Roger made similar observations and comes to the same conclusion as Brown-Séquard. Van Engelen demonstrated that absorption is much retarded in shock. Contjean has also demonstrated the same fact. Frank Vale has confirmed these experiments of Roger and Contjean and [illegible] Brown-Séquard's experiments [illegible] primarily due to an arrest of [illegible] arrest of cell activity and that it cannot be due simply to exhaustion or paralysis of the nerve centres. It seems to me that these arguments are not conclusive and that we can quite well attribute the arrest of metabolic processes to the fall in blood pressure.

Further proof that exhaustion of the vaso-motor centres is the cause of shock is afforded by the fact that when profound shock has been established procedures which normally produce marked stimulation of the vaso-motor centres with a corresponding rise in blood pressure have no such effect—such procedures, for instance, as electrical or traumatic stimulation of large nerves, injection of strychnine into the veins, asphyxia, &c., all of which must produce a rise in blood pressure if the vaso-motor centres are not exhausted. Crile argued that if shock is produced by exhaustion of the vaso-motor centres it should be possible to produce shock by cutting out the action of the vaso-motor centres in a healthy animal. This was done by injecting into the medulla a 2 per cent. solution of cocaine. At the time of the injection the blood pressure was 115 millimetres of Hg; immediately afterwards it fell to 50 millimetres, that is to say, to the level of profound shock. Respiration stopped and artificial respiration had to be supplied. While the pressure was at this level electrical stimulation of the sciatic nerve, the injection of strychnine, and other methods which normally caused a rise produced no alteration in the blood pressure. After the animal had been in this condition of profound shock for some time, *during which no form of stimulation caused any rise in the blood pressure*, 22 minims of adrenalin were injected; the pressure at once rose to 250 millimetres of Hg and this pressure was sustained for nearly two minutes. Crile repeated this experiment several times with the same results (Fig. 3). This experiment affords a further and most emphatic proof that exhaustion of the vaso-motor centres is the cause of shock. A similar result is also obtained if the vaso-motor centres [illegible] (Fig. 4.) [illegible] upon animals have been [illegible] *of the blood pressure* during surgical operations upon man. Some of the earliest clinical obs[illegible] made by Kapsammer working with the Gaertn[illegible] Riva-Rocci [illegible] many obser[illegible] clinical obs[illegible] procedures [illegible] and others have also recorded numerous observations. Also working with the Riva-Rocci instrument I have for some time kept careful records of the blood pressure during surgical procedures and a considerable amount of valuable [illegible] has thus been acquired. Injury to important [illegible] an produces a fall in blood pressure [illegible] as found to be the case by *Crile* in dogs. Evulsion of the Gasserian ganglion causes a considerable fall in blood pressure and shock results; this was observed

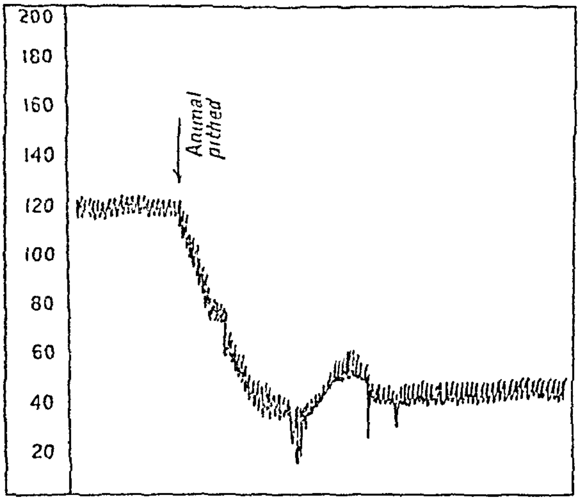
FIG. 3.



in two cases by Cushing. During amputation of the penis for epithelioma in an old man Crile observed a fall in pressure from 190 millimetres to 112. During an operation upon a scrotal hernia in which a firmly adherent sac was dissected off the cord Crile observed a fall in blood pressure from 152 to 58 millimetres. In one case of extensive removal of the breast for carcinoma in which during the process of clearing the axilla there was considerable traction upon the brachial plexus I observed a fall in pressure from 135 millimetres to 60 millimetres; the pressure soon rose again but remained for some time between 80 and 100 millimetres and a slight degree of shock developed, the pressure not returning to its previous level for over 24 hours. In another case of a very difficult excision of the shoulder for an old dislocation in a woman, aged 53 years, the pressure fell from 160 millimetres to 95 millimetres. In all cases where careful observations of the blood pressure during operation are taken the fall in blood pressure and shock which occurs is found to be in proportion to the duration of the operation, the amount of traumatism to which the tissues are subjected, the loss of blood, and the importance of the nerves in the field of operation.

In operations upon the abdomen there is usually a steady decline in the blood pressure. In the earlier stages of an abdominal operation irregular rises in blood pressure are usually noticed due to stimulatory effects from traction or trauma of the peritoneum; during the later stages a steady fall is usually observed. The extent of the decline in blood pressure is influenced very much by the amount of exposure of the peritoneum and the amount of traumatism to which it is subjected. In the case of a woman, aged 55 years, who was operated upon for the removal of an enormous fibroid of the uterus, the blood pressure fell from 140 millimetres to 70 millimetres in the space of two hours and a dangerous degree of shock developed. During an operation for gall-stones the blood pressure fell from 200 millimetres of Hg to 125 millimetres of Hg in 35 minutes The reason why shock tends to develop as the result of abdominal operations or injury is probably two-fold. In the first place the removal of the support of the abdominal wall from the contained viscera allows dilatation of the splanchnic blood-vessels to occur and this tends to lower the blood pressure. Secondly, any operation upon the abdominal contents means considerable mechanical insult to the sympathetic nerves.

FIG. 4.



The easiest and clearest way of describing the physiological sequence in the causation and development of surgical shock and of showing the different physiological factors in their true relation to one another and to the result is to describe the course of events in a case in which shock develops as the result of some surgical operation. I believe the course of events to be somewhat as follows. A fall in general blood pressure takes place or tends to take place. This will immediately be compensated for by the vaso-motor centres; vaso-constrictor impulses will be sent out and the pressure will rise again, or if this takes place with sufficient rapidity will not fall. Of course, if the shock is due to a primary breakdown of the vaso-motor centre this stage of compensation will be absent. If the cause of the original fall in blood pressure continues this compensation will sooner or later become insufficient to maintain the blood pressure and the aid of the heart will be called in by means of the cardio-accelerator centre, and for a time by increased action the heart will help in maintaining the mean pressure. This we see by the fact that in the development of shock the rapidity of the pulse is increased. As the vaso-motor centre becomes exhausted, however, a point will be reached when, in spite of the increased action of the heart, it is no longer possible for the pressure to be maintained at the normal level and consequently a fall in general blood pressure will occur. Directly the blood pressure has fallen below a certain level the circulation will become partially inefficient and not only will the circulation of the different nerve centres be impaired but the blood itself will not be properly oxygenated owing to the pressure not being maintained in the lungs. This will affect all the great nerve centres and will tend to hasten exhaustion and to prevent recovery of the vaso-motor centres. As the vaso-motor mechanism breaks down there will be a tendency for the blood to collect in the large venous trunks and especially in the large splanchnic veins. This will interfere with the intake of the heart. As the output of the heart is directly proportional to its intake and the latter is diminished owing to stagnation of the blood in the great venous trunks supplying the right auricle, the former will be proportionally diminished. It has been proved experimentally by Crile and other observers that the output of the heart is not dependent upon the aortic blood pressure but upon the pressure in the vena cava. As the supply of blood to the right side of the heart is diminished it will beat more and more rapidly to try to compensate for the small volume of blood which it has to act upon. At the same time there will be transudation of fluid from the blood-vessels into tissues or in the case of abdominal injury into the peritoneum and the specific gravity of the blood will be increased. And as the result of the falling blood pressure and failure of the circulation the general cell activity of the body will be arrested or diminished and all metabolic processes will cease and death will ensue.

Surgical shock is the result of a general vaso-motor paralysis, the primal cause being exhaustion of the vaso-motor centres. Other centres, such as the cardiac and respiratory centres, are only affected secondarily in most cases. As one would naturally suppose, shock and the conditions which give rise to it cause very marked alterations in the action of the heart. The pulse-rate affords a useful guide to the condition of the vaso-motor mechanism during operative procedures secondary only in importance to the blood pressure. In most of the blood pressure charts taken during operations the pulse-rate has been recorded at the same time as the blood pressure, and it is noticeable in these charts that during the early stages of the operation the pulse-rate follows the blood pressure. That is to say, that a rise in the blood pressure is usually accompanied by an increase in the pulse-rate and *vice versâ*. During the later stages of severe operations, however, when the blood pressure has reached a low level or when shock has developed, a fall in the blood pressure is accompanied by an increase in pulse-rate and when the blood pressure rises again the pulse-rate decreases. This shows that the heart by increased action is attempting to compensate for the fall in blood pressure and that the vaso-motor mechanism is becoming inefficient to hold up the blood pressure by itself.

I do not wish to argue that the only centres affected in shock are the vaso-motor centres. There can, I think, be no doubt that all the other centres are more or less affected in profound degrees of shock. But I think that as regards the production of the phenomena of shock the exhaustion of the vaso-motor centres and the consequent general vaso-motor paralysis is the primary factor and that the other centres are for the most part secondarily affected and that the other phenomena of shock are the result of this vaso-motor paralysis and the resulting fall in general blood pressure. In many cases of shock there is a marked *toxic element* present. We see this in cases were patients die apparently from shock soon after operations upon the abdomen, where septic peritonitis or intestinal obstruction are found to be present. Such cases often die from shock, though the severity of the operation is not sufficient by itself to account for the condition. In such cases direct poisoning of the nerve centres, especially of the vaso-motor centres by the toxins in the blood, *is a factor* of no inconsiderable importance in the production of exhaustion and paralysis of these centres. After all the step from exhaustion produced by over-stimulation or overwork of the vaso-motor centres to that of poisoning by toxic products in the blood is no great one. And in many cases of death from shock after operations for conditions where there is septic peritonitis or a similar condition present I believe this toxic element to be an important contributory factor in the production of shock. That this toxic condition of the blood may cause marked effects upon the nerve centres and may cause a fall in the blood pressure we have abundant evidence in the low blood pressure found during the critical stage of almost all acute infections, such as pneumonia, diphtheria, t [illegible] differs from shock r [illegible] tor centres are not exhausted. The symptoms in the two conditions are almost identical but whereas in shock the vaso-motor centres are exhausted in collapse their function is suspended. Collapse is the condition due to a sudden great fall in blood pressure resulting from a severe hæmorrhage or from a great and sudden loss of circulating fluid such as occurs in cholera; or from a sudden suspension of function or paralysis of the vaso-motor centres resulting from some violent afferent nerve impulse as, for instance, a blow in the splanchnic area or upon the genital organs. The symptoms in shock and collapse are practically identical. In shock, however, the condition develops gradually, whereas in collapse it develops suddenly or at any rate rapidly. There is, however, a very important difference in the way in which these two conditions react to treatment. In shock treatment is very difficult and often unsatisfactory since we have to deal with *exhausted* nerve centres. In collapse, on the other hand, treatment is much more likely to be effective, since the cause is either a lack of circulating fluid, which can be remedied, or a suspension of function of nerve centres, it being only necessary to set them going again. Crile has demonstrated that animals dying from collapse can be resuscitated 15 minutes after they are apparently dead. A dog apparently dead from the effects of an electric current of 2300 volts was restored to life and in a patient whose heart had ceased beating for nine minutes the normal functions were restored for 32 minutes.

ABSTRACT OF

The Hunterian Lectures

ON

THE CHANGES PRODUCED BY INFLAMMATION IN THE CONJUNCTIVA.

Delivered before the Royal College of Surgeons of England on Feb. 27th and March 1st and 3rd, 1905,

BY M. STEPHEN MAYOU, F.R.C.S. ENG.,

CHIEF CLINICAL OPHTHALMIC ASSISTANT AT THE LONDON HOSPITAL AND AT THE ROYAL LONDON OPHTHALMIC HOSPITAL.

LECTURE III.[1]

Delivered on March 3rd.

TRACHOMA.

MR. PRESIDENT AND GENTLEMEN,—Trachoma, I think, is a specific infective disease of the subepithelial lymphoid tissue of the conjunctiva, characterised by the formation of follicles and by infiltration, which go on to subsequent cicatrisation and partial obliteration of the conjunctival sac. Clinically the disease usually appears at first in the upper fornix and is characterised by the formation of follicles. These follicles may remain for a long time and reach a large size without giving rise to any symptoms. At other times a muco-purulent conjunctivitis is set up. This muco-purulent conjunctivitis does not occur in all cases nor at the same period of any particular case, and indeed may not occur at all throughout a case. Pyogenic organisms are always found in the discharge and indeed I think the purulent discharge in these cases may be looked upon as a septic infection of the conjunctiva in addition to the trachoma which without doubt lowers the vitality of the tissue and provides a means of entrance to the organisms by rupture of the follicles. This muco-purulent conjunctivitis may have varying effects on the disease. It may be associated with increased spread, as is seen in the most virulent cases, which are usually accompanied by a quantity of discharge; or it may bring about its cure, the reasons for which will be discussed more fully when speaking of its pathology. Not only are follicles formed in the subepithelial tissue but diffuse infiltration of the tissue occurs, the conjunctiva appearing red, brawny, and swollen. Although, pathologically speaking, follicular formations and infiltration do not occur apart, they receive names to distinguish them clinically in this disease. Hence the terms follicular, papillary (in which the infiltration is chiefly superficial), and brawny œdema (Stelwag) in which deep infiltration is broken up by fibrous tissue.

The etiology of pannus will be discussed with its histology.

Histology.—These observations were made on sections from over 30 cases of trachoma.

[The appearances noted in the epithelium and the follicles were then described.]

CONCLUSIONS AS TO THE ORIGIN AND EFFECTS OF THE DISEASE ON THE CELLS OF THE FOLLICLES.

As we have already seen, trachoma is produced by direct infection. The actual cause of the disease has not yet been discovered and although numbers of organisms have been described none has yet been identified as pathogenic to the disease. Without doubt, whatever the cause of the disease, it has a very powerful action on the cells, for we have seen the amount of destruction it produces in the centre of the follicles where, presumably, the disease is most active. As a result of the destruction of these cells hyaline material is formed which may subsequently develop other changes. In the follicles of follicular conjunctivitis we find great numbers of plasma cells, whereas in a definitely trachomatous follicle they are practically absent. Now if plasma cells are derived from the endothelium with the lymphocytes, how is it that they do not appear in the follicles of trachoma? The answer to this question seems to me twofold. First, plasma cells, to judge by their intensely basic staining reaction, are probably young cells and very active proliferation of the endothelium is not taking place. Secondly, I have shown that plasma cells are not very resistant to toxins and are easily broken up; hence, if formed, they would quickly disappear. Indeed, Whitfield has suggested that the presence of these cells is evidence of the attempt at the production of local immunity in the part.

It has been stated that follicular conjunctivitis and trachoma are identical diseases and that the milder follicular conjunctivitis is simply the beginning of trachoma. This statement was made *before the introduction of plasma* stains and I need hardly say is incorrect. All the follicles in trachoma do not show the changes above described but many of them show no change beyond that found in the so-called follicular conjunctivitis. This, I think, is due to the fact that they are not infected with trachoma, for if we take an analogous example, such as in rare cases of tuberculosis which affects the follicles, necrosis can be seen in some of the follicles, lying side by side with perfectly healthy follicles. The effect of the tubercle bacillus on the cells is very nearly *allied to* trachoma, causing destruction of the plasma cell at the most active site of the disease, with an increased formation outside the diseased area. Similarly, in the early stages of tuberculosis of the lymphatic glands, there are often found follicles in the same gland which are not affected with the disease. I take it, therefore, that the granules in trachoma are follicular formation *plus* trachomatous infection, the follicles being simply an effort on the part of the tissues to produce mononuclear cells and becoming secondarily infected with trachoma. Although, indeed, as a general rule, a considerable number of them seem to be infected even in quite the early stages, as is evidenced by the cells beginning to show signs of degeneration and by plasma cells being absent, yet follicles can be found in trachoma which are packed with well-formed plasma cells and are evidently not yet infected with trachoma. These follicles may contain considerably more plasma cells than those of follicular conjunctivitis.

---

[1] Lectures I. and II. were published in THE LANCET of March 4th (p. 545) and 11th (p. 625), 1905, respectively.

The Differential Diagnosis of Follicular Conjunctivitis and Trachoma.

Clinically the differential diagnosis of trachoma and follicular conjunctivitis is made principally from the following facts: 1. The follicles in follicular conjunctivitis are found principally in the lower fornix, whilst those of trachoma are in the upper. Follicles on the tarsus are more frequent in trachoma. 2. The absence of scarring in follicular conjunctivitis. 3. The absence of pannus in follicular conjunctivitis. 4. It has been said that trachoma is most common in adults although I think that there is considerable doubt about this statement, whereas follicular conjunctivitis occurs principally in children.

Microscopically: 1. Smear preparations from the conjunctiva obtained by gentle friction contain an enormous number of plasma cells in trachoma; in follicular conjunctivitis, although the discharge often contains a certain number, they are not found to the same extent. 2. Sections: (*a*) *The epithelium* in follicular conjunctivitis, although showing extensive mucoid change, does not dip down into the tissue to the same extent and there is not so much new gland formation. (*b*) *The subepithelial tissue* in trachoma consists almost entirely of plasma cells; in follicular conjunctivitis, although they occur in large quantities near the follicles, they are not packed together beneath the epithelium as they are in trachoma. (*c*) In trachoma there is an increase in the fibrous tissue which often contains a large number of mast cells; the mononuclear exudation extends into the deep layer of the conjunctiva. In follicular conjunctivitis the deeper layers of the conjunctiva are unchanged. The follicle in trachoma contains practically no plasma cells and in the centre the cells are undergoing necrosis and there are very few cells undergoing mitosis.

Epithelioid-like cells are absent from the follicles of follicular conjunctivitis but are present in trachoma. The older follicles of trachoma contain considerable numbers of well-formed connective tissue cells, which are practically absent in follicular conjunctivitis. In sections from both diseases, one finds usually follicles of varying age; it is therefore generally possible to make a differential diagnosis. But it must also be remembered that a trachomatous conjunctiva may have a healthy follicle, which may contain even a greater number of plasma cells than in follicular conjunctivitis. The most important point in determining the diagnosis is the necrosis of the cells, which in trachoma can not only be seen in the follicle but in the infiltration. (See Stelwag's brawny œdema.)

The Histology of the Bulbar Conjunctiva in Trachoma.

The epithelium shows some short papilla-like processes which dip down into the subconjunctival tissue. It is also somewhat thickened on the surface.

Subepithelial tissue.—It is usually stated that the bulbar conjunctiva is unchanged in trachoma. This is not, strictly speaking, correct. I have had the opportunity of examining three cases of bulbar conjunctiva in trachoma removed by peritomy in which there were considerable infiltration of the lids and well-marked pannus. The subepithelial tissue shows a great increase in the number of plasma cells and some chorioplaques. A quantity of new vessels with a proliferating endothelium are also seen. As the limbus is approached this layer is greatly increased in thickness and the plasma cells in the deeper layers show extensive degeneration. At the limbus there are found a number of collections of lymphocytes and mononuclear leucocytes surrounded by masses of plasma cells in every stage of degeneration. These masses of leucocytes degenerate into epithelioid-like cells towards the centre. There are no plasma cells in these masses although the surrounding tissue consists practically of nothing else. In fact, the whole appearance is similar to the follicles seen in the lids except that these follicles at the limbus are smaller in size, contain no darkly staining outer zone, and have a smaller number of plasma cells.

Conclusions as to the Changes at the Limbus.

There has been considerable discussion as to whether the condition of the limbus is a true infection with trachoma or not. I think from examining the above-described sections that the answer is without doubt in the affirmative. It is generally admitted that the bulbar conjunctiva is not affected with trachoma. No doubt as the result of the irritation produced by the friction of the granules over the surface it becomes filled with well-formed plasma cells, showing that the disease is absent, but as the limbus is approached the tissue alters entirely. The plasma cells disintegrate and masses of mononuclear leucocytes make their appearance, whilst at the limbus we find plasma cells completely absent and the mononuclear cells in every stage of degeneration forming a typical trachomatous follicle, similar to that seen in the fornix.

Histology of Pannus.

I have only been fortunate enough to cut sections of one case of pannus in which the eye had been hardened in alcohol. Clinically, the case was of not very great severity, the pannus covering about the upper third of the cornea and not very dense.

The epithelium over the surface of the cornea was slightly thickened and towards the lower margin of the pannus a break in the epithelium, evidently a small ulcer, could be seen.

Subconjunctival tissue.—Beneath the epithelium there were a considerable number of new vessels surrounded by lymphocytes and plasma cells. These had formed a more or less rounded accumulation somewhat resembling a modified follicle. Clinically I have seen cases of very thick flesh pannus in which if sections had been made I am sure that true follicular formation would have been found. Indeed, I think that pannus is nothing more than the spread of the disease from the limbus to the cornea modified by the dense nature of the tissue and the absence of the blood-vessels.

Histology of the Various Forms of Trachoma.

Papillary trachoma.—In this form of trachoma the conjunctiva, when examined clinically, is seen to be covered with minute papillæ, like the pile on velvet. As a rule this condition is found in the early stages of trachoma and as it subsides the follicles make their appearance.

Histology.—*The epithelium* is thrown into folds by the swelling beneath, the surfaces in apposition showing mucoid change; in fact, they form the so-called new glands.

The subepithelial tissue consists of an exudation of mononuclear leucocytes and plasma cells, the plasma cells being principally found directly beneath the epithelium, especially at the summit of the papillæ. Beneath the papillæ are found typical trachomatous follicles which are usually small and the existence of which is masked by the papillæ. There is comparatively little fibrous tissue; in fact, the papillary condition seems to be characteristic of the early stage of the disease.

Brawny œdema (Stelwag).—In this condition the upper palpebral conjunctiva is converted into a pale gelatinous-looking tissue; it is usually associated with much scarring and is generally found in cases of trachoma of long standing. Microscopically the condition is of considerable interest.

The epithelium is thickened and is often keratinised and, unlike the other forms of trachoma, is not thrown into folds but is smooth on the surface.

The subepithelial layer consists of infiltration much broken up by fibrous tissue, there being practically no follicular formations. The infiltration consists of a few mononuclear cells and a large number of plasma cells; these latter cells are found in all stages of degeneration, their cytoplasm being much broken up but still taking the pyronine stain. When separated from the cell this material is found both free in the infiltration and scattered through the fibrous tissue, constituting a form of hyaline degeneration. The newly formed fibrous tissue takes up the pyronine of Pappenheim's stain on that account. Sometimes this hyaline material goes on, no doubt, to secondary changes, such as amyloid and calcareous degeneration.

Phlyctenulæ.—Clinically, in its simplest form a phlyctenule is a small red eminence of about the size of a millet seed, usually seen in the ocular conjunctiva, in the region of the limbus, with a leash of dilated vessels leading up to it. As a rule, the epithelium on the surface of the eminence gives way, with the extrusion of the contents and the formation of a greyish looking ulcer, which rapidly heals. Occasionally these nodules disappear without the formation of an ulcer. Almost invariably the disease is preceded by some other form of conjunctivitis, it being very rare to find a case in which there has not been some slight discharge beforehand if the history be carefully inquired into.

The position of the phlyctenule is by no means limited to the limbus, although without doubt that is the most common situation for the lesion. It is found in other parts of the bulbar conjunctiva and, according to H. Herbert,[2] it occurs on the palpebral conjunctiva. This statement I have had the opportunity of verifying in a child suffering from a muco-purulent conjunctivitis due to the staphylococcus pyogenes albus, accompanied by pustules on the face due to the discharge from the eye. On the outer side of the limbus was a typical phlyctenule. On everting the upper lid there were three or four follicular-like enlargements on the palpebral conjunctiva covering the tarsus, one of which was ulcerating. There were no other follicles in the upper or lower fornices or in the other eye. A piece of this tissue containing two of the phlyctenulæ was removed for examination. The other phlyctenules disappeared in one week under protargol. Finally, phlyctenulæ may start in or spread to the cornea from the limbus, and when lasting for some time become vascularised by the budding out of the endothelium of the vessels from that region.

The number of the phlyctenular varies considerably. In some cases there are only one or two; in others they may be extremely numerous, the conjunctiva in the neighbourhood of the limbus being covered with very small nodules which do not usually break down into ulcers but resolve. In cases in which the discharge from the eye runs down over the face numerous pustules are formed in the skin from direct infection. The patients are usually children, although not invariably so, and are as a rule run down in health. It is stated that these children are always tuberculous and it is supposed by some authorities that these lesions are of a tuberculous nature, but since the surroundings which give rise to both diseases are the same this theory is of but little value, especially as the pathological changes do not bear it out.

Histology.—I have had the opportunity of examining eight cases microscopically which showed most of the stages of the disease.

[illegible] of phlyctenular con-jun[illegible] berculosis, is essentially ass[illegible] patient and diminished resistance to bacterial invasion. Hence it is only natural that these diseases should often be found in the same subject. The discharge in cases of phlyctenular conjunctivitis runs over the face and produces suppurating points in the skin. We know that if the staphylococcus is rubbed into the skin it will produce similar suppuration. But Leber, like Bach, has been unable to reproduce the disease by inoculating the healthy conjunctiva with the pus from these points. This, I think, may probably be accounted for in the same way that crops of boils constantly recur in the skin in patients who are out of health through reinfection from the discharge but cease to form directly the health is re-established. With regard to the histology, although in the early stages the exudation is chiefly mononuclear it becomes polynuclear before rupture takes place, a point which is almost positive evidence of the presence of pyogenic organisms. The occurrence of the mononuclear cells I think can be accounted for by the special tendency of the conjunctiva to form mononuclear cells, as has been shown when treating of the lymphoid tissue of the conjunctiva. The most frequent seat of phlyctenulæ is the limbus, a point at which the conjunctiva is attached firmly to, and supported by, the globe, so that the lid, passing constantly over the surface, is more likely to rub the organism in. Although the corneal conjunctiva is equally subject to friction from the lid the entrance of organisms is probably hindered to some extent by Bowman's membrane although phlyctenular ulcers do occur here also. Another factor undoubtedly is the absence of lymphoid tissue, for we find that phlyctenulæ only occur where none exists.

The whole course and histology of a phlyctenule correspond very closely to those of a boil on the skin, to which, I think, it is exactly comparable, with the exception that it occurs in a thin membrane in which rupture takes place very early. In the cornea where the tissues are thicker definite macroscopic abscesses are occasionally found. When the disease starts in, or spreads to, the cornea the ulcer which is produced often persists for a considerable time, the endothelium of the vessels which bud out from the limbus vascularising its base. The long duration of a phlyctenular ulcer in the cornea compared with that of one at the limbus is very marked, which is, I think, accounted for very largely by the non-vascular condition of the cornea, for we have seen that a healing phlyctenule at the limbus consists practically of new vessels and proliferating endothelium.

The comparative absence of the plasma cell in this disease is of considerable interest. We have seen that this cell does not make its appearance to any extent during acute inflammatory processes but that in tuberculosis around the foci of the disease they are present in enormous numbers. In other words, the non-appearance of the plasma cell in phlyctenulæ is indicative of an acute inflammatory process and therefore not due to tubercle which produces plasma cells in enormous numbers. In the healing stage plasma cells are not present to any extent and we have already seen in trachoma, &c., that the presence of the plasma cell is an indication of local immunity. So again in phlyctenulæ their non-appearance is associated with the fact that phlyctenule after phlyctenule can recur about the same region.

VERNAL CATARRH.

Histology.—The condition is one of enormous papillary overgrowth of the conjunctiva.

The epithelium is thickened over the surface of the papillæ and in the folds dips down into the underlying tissue. As a rule these processes show comparatively little mucoid change.

Subconjunctival tissue.—The papillæ on the tarsal conjunctivæ are very hard and consist of a quantity of dense connective tissue. It has been pointed out by Herbert[3] that in addition to the ordinary connective-tissue cells there are a quantity of eosinophile cells and that these cells are present in the discharge—a point which he considers diagnostic. I have examined six cases histologically and can confirm this point in every way. The eosinophiles, both polymorphonuclear and mononuclear, are found in enormous numbers in the discharge, whole fields of the $\frac{1}{12}$th often containing no other cells. The granules from the cells which are often rupture[illegible] the specimen they are best [illegible] with Leishman's methylene blue compound. In the tissue they are far fewer in proportion than the other leucocytes, their appearance in such large quantities in the discharge being due to their greater power of amœboid movement. They are situated principally in the small vessels lying beneath the epithelium and can be seen coming through the vessel walls, being derived from the blood. I could find no evidence of proliferation of these cells in the tissue. According to Herbert they make their way through breaks in the epithelium. Although this is so, all my sections show them actually in the epithelium, making their way through it. In addition to these cells there are considerable numbers of plasma cells, most of which show marked necrosis, evidently due to the presence of some powerful toxin.

SUMMARY OF THE CHANGES WHICH OCCUR IN THE SUBEPITHELIAL TISSUE OF THE CONJUNCTIVA AS THE RESULT OF INFLAMMATION, AS SHOWN BY THEIR HISTOLOGY.

In studying inflammation in the conjunctiva we are dealing with a tissue which is very responsive to the slightest stimulus and the cells of which are normally undergoing proliferation in the superficial layers. It is moist and warm, well supplied with blood, nerves, and lymphatics—all factors which assist in rapid tissue changes.

The cells.—The character of the cells found in the exudation depends on the character and degree of virulence of the toxin introduced into the conjunctiva; if this be extreme, as in the case of the pyogenic micro-organisms, there follows a response, not only locally in the tissue of the conjunctiva, but from other tissues of the body, such as the bone marrow, with the resultant exudation in the conjunctiva of polynuclear leucocytes[4] brought by the blood stream from these organs to the inflamed conjunctiva as seen in the early stages of a wound or in acute muco-purulent ophthalmia. When the toxin is not so virulent, especially when the subepithelial tissue is directly affected, as in the early stages of a phlyctennle, the local response on the part of the tissue is the production of mononuclear leucocytes. These cells are probably derived from the rapid proliferation of the perithelium and endothelium of the blood-vessels, lymphatics, glands, &c., which in the conjunctiva produce these cells with enormous rapidity.

---

[2] Ophthalmological Review, 1898.

[3] British Medical Association Meeting, 1903.

[4] The polynuclear leucocytes are mostly neutrophile, but in some forms of exudation, such as that occurring in vernal catarrh, the eosinophile cells may predominate.

The conjuuctiva is always receiving a certain amount of irritation and therefore is producing mononuclear cells, the only period at which these cells are absent from the tissue being the fœtal stage of existence, when naturally no irritation occurs. Now when the degree of irritation is increased, as in the case of atropine irritation or in the later stages of Koch-Weeks conjunctivitis, there is an increased call on the tissue for the production of mononuclear cells, followed by the formation of follicles. This follicular formation also occurs in children without any special cause of irritation at the age when the lymphoid tissue is unusually active and is then known as follicular conjunctivitis. The follicles are either small and discrete or large and containing a number of other follicles (which I have called endo-follicles); the latter variety are identical with lymphatic glands which, like the follicles, may be of new formation. Subsequently these follicles, like the lymphatic glands, can become the seat of disease, such as tubercle, trachoma, &c., and undergo secondary degeneration changes, such as hyaline, amyloid, &c.

In all inflammatory changes of any duration the plasma cell is produced, its presence in large numbers signifying that the disease is chronic or of a non-virulent type such as diplobacillary conjunctivitis. Its origin is closely allied to the mononuclear leucocyte, its structure and staining reaction being very similar to the large mononuclear leucocyte; in fact, the plasma cell is possibly nothing more than a slightly altered large mononuclear leucocyte, and is probably a young cell, because of its basic staining reaction. It may be either directly derived from the mononuclear cells or differentiated in the process of their formation from the perithelium and endothelium. It seems to me impossible that the plasma cell can be, as is stated by Unna, derived from the fixed connective-tissue cell for reasons already given.

The great importance of these cells in conjunctival disease is that, if they are formed, they show the situations in which disease is present by disintegrating in that area; and, conversely, by their presence they show the local immunity of the area in which they are found, for if we look at sections from ophthalmia neonatorum of some duration we find the deeper tissue packed with plasma cells, whilst directly beneath the epithelium, which is known to contain the organisms producing the disease, plasma cells are absent. Between these two areas, one consisting almost wholly of plasma cells and the other having practically none, we find plasma cells in every stage of disintegration. In the follicles of the so-called follicular conjunctivitis (normal lymphoid tissue) they are present in large numbers, whilst in the trachomatous follicle they are broken up. Again, in the bulbar conjunctiva of trachoma, which is admittedly not affected with the disease, they are present in large numbers, but as the limbus is approached they decrease and disintegrate, and in the diseased follicle at the limbus they are absent. Again, in wounds of the conjunctiva they appear in 12 hours, simultaneously with the comparative cessation of exudation of polynuclear leucocytes—that is to say, that the wound has become at that time locally immune from any organism it may contain if not acutely septic. Around a phlyctenule very few plasma cells are found, in connexion with which fact we note that phlyctenulæ constantly recur in the same situation.

The endothelial and perithelial cells, as well as being the probable origin of the mononuclear leucocytes and plasma cells, are strongly phagocytic, for it is seen that they take up the particles of silver oxide in argyrosis and also polynuclear and mononuclear leucocytes and plasma cells which within these cells undergo a process of digestion. They are so numerous in resolving follicles that it would seem they may account largely for the disappearance of the exudation after the cause of the inflammation is removed. No doubt also the disappearance of the exudation is assisted by the return of a certain proportion of its cells into the blood stream and the lymphatic vessels; but the whole subject of resolution and organisation is too vast to be treated here and belongs rather to the realm of general pathology than to that of the special pathology of the conjunctiva.

THE NATURE AND TREATMENT OF EPILEPSY.[1]

By WILLIAM ALDREN TURNER, M.D. Edin.,
F.R.C.P. Lond.,

PHYSICIAN TO OUT-PATIENTS AT THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, AND AT KING'S COLLEGE HOSPITAL; VISITING PHYSICIAN TO THE COLONY FOR EPILEPTICS, CHALFONT ST. PETER, BUCKS.

In bringing before your notice this evening some considerations upon the nature and treatment of epilepsy I am aware that I am referring to a malady which has been carefully and elaborately studied since the time of Hippocrates. The mere mention of this fact is a reason for its further study as there is a perennial interest attached to a disease so frequent in its occurrence, so graphic in its manifestations, and so intractable to treatment. Our knowledge of the mechanism of convulsions was enormously widened a generation or more ago by the elaborate physiological investigations upon the functions of the cerebral cortex but it seems to me as if the detailed study of convulsions which these investigations initiated had somewhat detracted from the more general study of epilepsy as a morbid entity, in which convulsions form only one, though an important, symptom.

It is only during the last decade that more attention has been paid to the chemical physiology of epilepsy, through a study of the fluids and secretions of the body, from which interesting and suggestive information has been obtained. From the use of finer means of staining nerve cells and their processes, from a more intimate knowledge of the association tracts in the central nervous system, and from the study of statistical data, afforded by the accumulation of epileptics in special institutions, facts have been obtained bearing upon the natural history of the disease which previously were difficult to ascertain.

It is not proposed to do more than refer to the classical fit, well known to all physicians and described in detail in textbooks on medicine. But I cannot refrain from quoting a graphic account of the grand mal seizure given by Lucretius,[2] a writer who has been able to cloak with poetical feeling one of the most gruesome sights within our knowledge. Writing some twenty centuries ago he thus describes an epileptic seizure:—

> "Oft, too, some wretch, before our startled sight,
> Struck as with lightning, by some keen disease,
> Drops sudden: By the dread attack o'erpowered
> He foams, he groans, he trembles, and he faints;
> Now rigid, now convulsed, his labouring lungs
> Heave quick, and quivers each exhausted limb.
> Spread through the frame, so deep the dire disease
> Perturbs his spirit; as the briny main
> Foams through each wave beneath the tempest's ire.
> He groans since every member smarts with pain,
> And from his inmost breast, with wontless toil,
> Confused and harsh, articulation springs.
> He raves since soul and spirit are alike
> Disturbed throughout, and severed each from each
> As urged above distracted by the bane.
> But when at length the morbid cause declines,
> And the fermenting humours from the heart
> Flow back—with staggering foot first treads,
> Led gradual on to intellect and strength."

We readily recognise in this description the main elements of the major seizure: the sudden onset, the fall, the epileptic cry, and the loss of consciousness, the tonic followed by the clonic convulsions, and the stertorous breathing. Then ensues the period during which the whole body is swept by the convulsion so that death seems imminent. Now follow a return to consciousness, with attempts to move and to speak, and the termination of the fit.

Although this is the common manifestation of epilepsy there are also seen the minor or petit mal attacks in which consciousness is more or less obscured with or without slight motor spasm. Of these two types of seizure, the commonest and the most frequently met with as the only epileptic manifestation is the major fit, then comes a combination of the major and minor attacks, and least frequently the petit mal occurring alone.[3]

[1] A paper read before the Leicester Medical Society on Feb. 8th, 1905.

[2] Quoted from Peterson: National Association for the Study of Epilepsy, 1901, p. 11.

Epileptic equivalents.—Although these two types may be described as the classical manifestations of epilepsy there are other clinical phenomena sometimes met with in epileptics, at other times as independent symptoms, which stand in close relation to the psychical condition underlying epilepsy. The phenomena about to be described present many points of interest, are of rarer occurrence than true epilepsy, and are more difficult to diagnose. Owing to the peculiar character of the phenomena, which occasionally partake of the nature of misdemeanour or even of crime, epilepsy is brought within the range of legal medicine. I refer to the phenomena known as psychical epilepsy or psychical epileptic equivalents. By epileptic equivalents are designated certain states of consciousness "differing not only from normal consciousness but from the state of consciousness that usually occurs in epileptic attacks" (Peterson). The term really signifies a psychical state that in some degree takes the place of an epileptic seizure. Assuming this to be the true interpretation of the term "equivalent" it would be an error to regard psychical epilepsy and its analogues as sequelæ of attacks which were either so slight or so transitory as to have passed unobserved. It is therefore necessary to distinguish between post-paroxysmal psychoses, or mental phenomena [illegible] epileptic equiva- [illegible] linary fits. This [illegible] quainted with the history of the patient which is frequently difficult to obtain in the circumstances in which he is seen.

The following characters may be accepted as sufficient reason for regarding psychical clinical manifestations as epileptic equivalents: (1) the occurrence in the family history of similar or allied conditions, interchangeable with forms of genuine epilepsy; (2) their association in the same person with the classical types of epilepsy; and (3) the existence of definitely epileptic characteristics, such as sudden onset, transitory duration, and irregular periodicity.

Perhaps the best known and certainly the most striking form of epileptic equivalent is that which is described as "automatic wandering" or epileptic ambulatory automatism. A number of such cases have been recorded but I may best illustrate the condition by referring to one which has come under my own observation.

The patient, a married man, about 40 years of age, after some prodromal irritability and a few days' severe headache, lost all knowledge of his surroundings for a period of ten days, during which time he carried out some of his ordinary duties, called upon his brother on one occasion, and then disappeared from his home in London. He had no recollection of anything until he came to himself again in Hull, where he applied to the police for assistance. During these ten days he had been seen by his wife, his brother, and a friend, none of whom noticed that he was different from his usual condition except that he seemed quieter and had a dazed appearance. He answered questions satisfactorily. He had no recollection as to how he journeyed from London to Hull or where he had spent the two nights after his departure from London. He had disposed of some of the money he had with him but his watch and other contents of his pockets were untouched. He had never had an epileptic fit although at times he said he had "felt queer." He had, however, been subject to periodic headaches. His little daughter has had chorea and his brother, who has also been a patient, has had an epileptic fit and a brief attack of acute delusional insanity requiring restraint.

The main feature of the epileptic ambulatory automatism is the existence of acts of an apparently purposive character with entire oblivion on the part of the patient. The condition more closely resembles the somnambulistic state than any other; so much so, indeed, that *some states of somnambulism in adults* appear to be epileptic in character. These attacks usually occur only at rare intervals and are of great practical importance from the medico-legal standpoint. [illegible] sting of the [illegible] or periodic falling asleep should also be regarded as an epileptic equivalent. It is not a common phenomenon but a few cases have been under my observation. In one case in particular attacks of falling off to sleep lasting from one to five minutes were interchangeable with what appeared to be petit mal seizures. A brother of the patient suffered from a similar malady and a sister was subject to epileptic fits.

The close relation which exists in some cases between epilepsy and migraine leads me to the belief that *some forms of migraine* should be classified as epileptic equivalents. The points to which reference may be made are the frequency of migraine amongst the ancestry of epileptics, the presence of periodic headache in those who are subject to epileptic seizures, and the not uncommon substitution of migrainous attacks in youth by epileptic fits in later years. Some writers, while admitting the not infrequent combination of the two phenomena in the same person, deny their identity, laying stress upon the mental deterioration which occurs in epilepsy but not in migraine. It will be shown that the mental impairment found in epilepsy is a symptom of the disease in the same way as are the convulsive attacks, whilst in the aberrant types of epilepsy or epileptic equivalents now under consideration mental enfeeblement is characteristically unobtrusive.

Before leaving this part of the subject a brief reference may be made to the question as to whether epilepsy may occur without loss of consciousness. It is well known that localised convulsions or Jacksonian epilepsy indicating focal irritation of the cortical motor region may occur without this phenomenon. In epileptic vertigo consciousness is impaired to only a slight extent. It is not unlikely that some forms of abortive epilepsy in which only the aura is present may be unaccompanied by loss of consciousness, but in these cases there will be found evidence of other attacks in which consciousness is obviously lost. There is a form of attack characterised by sudden jerks or jumps, so violent as to cause a fall or to make the patient drop suddenly what he may be carrying which may be unaccompanied by unconsciousness, but these rarely occur alone, being usually interparoxysmal motor phenomena. I do not think, therefore, it is legitimate to diagnose epilepsy unless there is evidence of loss or impairment of consciousness, although, as already shown, some incomplete epileptic manifestations may be unaccompanied by loss of consciousness.

The interparoxysmal mental state.—In addition to convulsions, "sensations," "faints," and giddiness, epileptics present, as a rule, some mental impairment, but whether the mental condition is an integral part of the disease or is a consequence of the seizures has been a subject of discussion.

The mental states found in epileptics are, as a rule, described under two heads: first, those which are incidental to the seizures and form the pre- and post-paroxysmal psychoses; and secondly, the interparoxysmal mental state. It is the latter condition which should be regarded as the typical epileptic ment [illegible] of this condition consist [illegible] defect of memory, more especially for recent events. This defect of memory constitutes the first grade of epileptic dementia and was found as the only mental impairment in about 31 per cent. of the cases. The second class embraces those in whom, in addition to the impaired memory, there are defective power of initiation and capacity for work. These epileptics are slow in comprehension and often lazy; many of them are also irritable and passionate. Then follows the third class, containing those who present the most typical features of epileptic dementia. Although not legally insane they require supervision.

I have elsewhere[4] attempted to show that the interparoxysmal mental condition found in epileptics is not [illegible] nce of the seizures, but is an expres- [illegible] which [illegible] —

1. A strong hereditary disposition to epilepsy or insanity [illegible] the production of the severer types of dementia and [illegible] se as a confirmed malady.

[illegible] the disease is a potent factor in determining the mental state its influence is incidental to, rather than causative of, dementia, for we may meet with a fair degree of mental integrity even after the fits have persisted for over 50 years.

3. The age at the onset of the convulsions influences to some extent the mental condition, for the earlier the onset of the disease, especially during infancy and childhood, the

---

[3] Of 189 cases of epilepsy, 106, or 56 per cent., were of grand mal type alone; 66, or 34 per cent., showed the combined grand and petit mal seizures; and 17, or 8 per cent, were of petit mal type.

[4] Transactions of the Royal Medical and Chirurgical Society, vol. lxxxvii.

of epileptics. According to Féré[6] this is merely a local expression of a general sclerotic change found throughout the cerebrum. The observations of Chaslin,[7] Alzheimer,[8] and others point to an extensive increase in the neuroglial tissue, although Binswanger[9] has contended against the constant presence of a cortical gliosis except in cases of old-standing epilepsy with well-marked mental deterioration. Small cystic tumours and angiomata have also been described as of not infrequent occurrence and having a definitely causative influence in the production of epileptic seizures. In senile epilepsy general arterio-sclerosis is common and may cause seizures by starving the cortex of blood and by the production of small thrombotic occlusions. In status epilepticus multiple punctate hæmorrhages are usual and have been credited with the cause of this condition. Whatever may be the nature of the lesion it is generally admitted that the seat of epileptic seizures is primarily the cerebral cortex.

The recent investigations of Clarke and Prout[10] have shown that the most striking changes are seen in the sensory cells of the second cortical layer. They have found these cells swollen and undergoing the usual chromatolytic changes indicative of a functional or nutritional alteration. In addition there was a marked neuroglial overgrowth, more especially of the outer cortical layers. In their view the essential phenomena of the disease are sensory in character, the motor manifestations being secondary. With [illegible] Dr. John Turner, of the Essex County Asylum, to conduct them and he has permitted me to make a preliminary communication upon what he has found and to show some illustrative lantern slides. The phenomena which he has observed consist in the formation of coagula in the veins, capillaries and arterioles of the cerebrum and cerebellum. The clots appear to be formed by the accumulation, and eventually amalgama[illegible] show that the coag[illegible] constituent of their [illegible] undergo a degenerative change and in process of time become absorbed. The chief consequence of these thromboses, which are extensive and readily recognised, is to deprive the cortical grey matter of the arterial blood necessary for its proper function and to produce a condition of blood stasis. If the coagulation and obstruction occur in the veins, as is commonly the case, the same result is brought about as if it occurred in the arterioles—viz., arrest of the arterial blood-supply to the affected cortical area The occlusion may be either partial or complete. If the latter distension of the vessel proximal to the obstruction may ensue, with the result that small hæmorrhagic extravasations take place either into the cerebral tissue or the perivascular sheath. These are no doubt the small hæmorrhages long ago described by Hughlings Jackson which have been seen in the brains of persons dying in status epilepticus. The nutrient artery of the cornu Ammonis is a common seat for thrombosis. It is shown that the coagula are not passive processes occurring during a moribund condition, as they exhibit vital phenomena, whereby blood-vessels are blocked and hæmorrhages occur. Apparently, as a result of the deprivation of arterial blood, produced in the manner described, the large pyramidal or Betz cells show charactistic changes. Such are mainly seen in a large swollen and clear nucleus. These changes were very similar to what has been described by Mott,[11] from the experiments performed by Hill upon ligature of the carotid arteries in dogs It may naturally be asked what evidence is there that these thromboses do not take place in consequence of the convulsions. The reply to this lies in the fact that such [illegible] -cessarily [illegible] it unless [illegible]

The essential feature for the development of convulsions would appear to be *deprivation of arterial blood, coinciding with capillary and venous stasis, from cortical motor areas* In the Kussmaul-Tenner experiments convulsions were produced as a direct consequence of ligature of the innominate arteries, the spasms stopping upon the release of the ligature. Leonard Hill[12] in his work upon the "Cerebral Circulation" [illegible] comp[illegible] to the [illegible] be produced, but less quickly, by experimental ligature of veins. Hill refers to the experiments of Hermann and Esher, who obtained convulsions by ligaturing the superior vena cava and azygos veins. Further reference to Hill's work makes it clear that there is no evidence of constrictor spasm of the cerebral blood-vessels in epilepsy. He writes: "Every experimental method employed to detect vaso-constriction failed and therefore the cerebral vaso-motor spasm theory of epilepsy and convulsions must be withdrawn from pathology.[13] … .. As to the dependence of idiopathic epilepsy on cerebral anæmia, whether produced by poison or diminution of blood flow, [illegible] I submit, however, th[illegible] of Dr. John Turner [illegible] unlikely cause of [illegible] capillary thrombosis and venous stasis. I am led to accept this view tentatively as a possible explanation of epileptic fits in general, from a consideration of some circumstances in which these seizures are prone to occur. First, the marked frequency of epileptic fits at night, especially during the hours of deepest sleep, immediately after falling off to sleep and an hour or two before waking, when the cerebral blood pressure is at its lowest and capillary stasis is most likely to ensue. Secondly, the frequency of epileptic seizures in association with acute inflammatory diseases, such as pneumonia, enteric fever, and scarlet fever, in which there are an increased coagulability of the blood and a tendency to venous thrombosis. In this category also may be placed the puerperium—a period which is notoriously prone for the incidence of epileptic fits.

A brief reference may here be made to the examination of the cerebro-spinal fluid in epilepsy. Cholin, one of the products of lecithin disintegration, has been found here. Donath[15] found it present in 15 out of 18 cases of epilepsy. It has also been found in diseases of the cerebro-spinal system in which there is clear evidence of the breaking up of nerve tissue, such as general paralysis of the insane and tabes dorsalis.

Chemical pathology.—Owing to the apparent insufficiency of the pathological changes found in the brains of epileptics to form a satisfactory explanation of the epileptic phenomena, a school of observers, more particularly in France, broke new ground in their endeavour to find the exciting cause of epileptic attacks in biochemical changes. Much of the most recent work upon epilepsy has been done in this line and numerous researches during the last decade have added largely to our knowledge. The general results of these investigations are of a confusing and contradictory character but a brief *résumé* of the chief points may not be out of place.

Although the toxicity of the urine in epilepsy had been the subject of some investigation prior to the work of Voisin[16] it is mainly by this author and his associates that the intoxication theory of epilepsy was elaborated. Voisin showed that immediately prior to a fit there was urinary hypotoxicity, gauged by injections into rabbits; that during the attacks the toxicity rose and reached a point considerably above normal after the fit (hypertoxicity). During the interparoxysmal periods the toxicity was comparable to that [illegible] Voisin based his [illegible] of the blood, [illegible], by the aid of [illegible] -ter the fit came [illegible] clearance from the blood of toxic [illegible] se observations to be correct, a plausible and seemingly satisfactory explanation of serial epilepsy and the status epilepticus was at hand, but subsequent investigations by Hebold and Bratz, Roncoroni, and others have failed to find the urine of epileptics more toxic than that of health. The general result of the investigations upon the toxicity of the blood in epileptics is also negative, the researches of Mairet and Vires,

Hebold and Bratz, and Herter having failed to obtain any positive or constant results from the injection of epileptic blood serum into rabbits.

From the study of blood toxicity we may turn briefly to the reaction of the blood in epilepsy. Haig suggested that there was a definite relation between excess of uric acid in the blood and such maladies as migraine and epilepsy; but treatment directed upon this theory has not proved of greater value than other methods of treatment conducted along conventional lines. Somewhat similar to the uric acid theory is the view of Krainsky[17] who propounds the doctrine that uric acid is not the toxic agent but a derivative in the form of ammonium carbamate, a substance having a convulsion-producing character as testified by its injection into rabbits. Pugh[18] has found a sudden fall in blood alkalinity immediately prior to a fit and a further diminution in the alkalinity after the convulsion, the average interparoxysmal alkalinity being lower than the average of normal cases.

The general conclusion to be derived from a study of the researches upon the blood in epileptics is that prior to a convulsive attack or series of attacks there is a diminution in the blood alkalinity, but whether this arises from retention of uric acid (Haig), from formation of carbamic acid (Krainsky), or from the presence of acid toxins as yet of undetermined nature and source, remains unproven. The stage of diminished alkalinity would correspond to the preparoxysmal period of clinical observers—a period characterised in some cases by mental phenomena such as irritability, lethargy, depression, and occasionally delusional states, and in other, though rarer, instances by an unusual sensation of well-being. It is not to be supposed that such symptoms are invariably present or are characteristic of all forms of epileptic seizure. They are found more especially in serial epilepsy—that is, epilepsy shown by frequently recurring fits for a few days, to be followed by an interval of freedom of greater or less duration; in cases in which two or three fits occur at a time; or in cases the type of which is an occasional severe convulsive attack. They are not present, so far as I am aware, in the petit mal type of the disease.

Treatment.—It will be readily seen from the foregoing remarks that the scientific treatment of epilepsy should consist in more than an endeavour to subdue the convulsive element of the disease by drugs. As it is impossible in this country to legislate against the marriage of epileptics and defective persons we shall, I suppose, always have epileptics with us. It is not possible in the limits of time at my disposal to do more than mention the special attention necessary in the upbringing of children predisposed to epilepsy, the particular lines along which their education should be conducted, the treatment of confirmed epileptics in institutions or colonies, and the regulation and direction of their work under supervision.

The remarks upon treatment will therefore be confined to the subjection of the seizures. At the outset it may be stated that there is no single specific remedy in the treatment of epileptic fits although the bromides come nearest to this definition. The influence of the bromide salts upon epileptic fits is variable. In the first place, bromide medication may arrest the seizures immediately or within a brief period of their administration. Under this heading are found the curable types of epilepsy, cases characterised by an absence of mental impairment and with fits recurring at long intervals—in fact, a mild type of the disease. If any given case is capable of arrest by treatment a satisfactory response will be apparent within a short period of the commencement of bromide treatment. Of 86 cases in which the fits were arrested for periods varying from two and a half to 25 years, rather more than 50 per cent. yielded to treatment within the first 12 months of regular bromide medication. Secondly, the bromides may induce a marked lessening in severity and frequency of seizures without their complete arrest. This is the common result of bromide treatment and is what may confidently be expected in the majority of cases in the early stages of the disease. Thirdly, the bromides may change the time incidence of the seizures, converting nocturnal into diurnal attacks or *vice versâ*. Fourthly, the bromides may exert no influence at all or may even make the attacks worse.

Bromide treatment should be commenced at the earliest possible time after the onset of the fits, as there is a greater prospect of arrest or improvement during the first five than during the second five years of the disease, although arrest of fits may occur after a duration of from 20 or 30 years. The administration of the bromides should be continued for a period the duration of which is to be determined by a study of each case separately but should not be less than two years. The dose usually given is, I think, too large. If benefit does not follow a daily dose of from 45 to 60 grains of one, or a combination, of the bromide salts, some other remedy or method of treatment should be sought. The large doses prescribed on the continent, from 75 to 150 grains daily, although no doubt suppressing the seizures for a time induce other and more serious phenomena. It has been shown that daily doses of from 150 to 200 grains of bromide salt produced slurring articulation, lassitude, and mental dulness, with abolition of the palatal and pharyngeal reflexes. Moreover, the bromides have an accumulative action. Laudenheimer[19] has proved that an epileptic taking ten grammes of bromide salt daily for eight days only excreted 35 grammes during that period. The blunting influence of the bromides upon the cortical motor cells has also been demonstrated by the fact that a considerably stronger electrical current is required to excite the cortical motor areas of dogs which have been dosed by bromide of potassium.

In confirmed epilepsy with mental deterioration all that can be expected from the continuous use of the bromides is diminution in the number and perhaps in the severity of the seizures. The daily 30-grain dose of bromide of potassium was stopped entirely for a month in each epileptic in a house at the colony for epileptics containing 24 patients, with the result that the total number of fits during the month rose from 278 to 402. The mental condition showed no material change.

Of the influence of the bromides upon the several types of epileptic fit it may be said that the grand mal seizure is that most amenable to their influence, the petit mal attacks and psychical equivalents being little influenced. In serial epilepsy and the status epilepticus, chloral in combination with the bromides forms the most effective remedy, while in the post-paroxysmal psychoses the bromides are of little service.

Various modifications of the bromides have been introduced of recent years. Bromipin being difficult to dispense and costly has not in my hands met with much success; bromocarpin has been especially advocated in the forms of seizure arising from intestinal auto-intoxication. Borax has been strongly recommended by some authorities. Unless in combination with the bromides I have not found it of great use, although a combination of borax and digitalis has been found serviceable in some cases of minor epilepsy. Belladonna is a remedy which should be tried in all cases in which the bromides have failed. Every now and again a case will be met with in which this drug produces remarkable and persistent arrest of the seizures.

A modification of the bromide treatment is to be found in the *opium-bromide therapy* recommended by Flechsig about 12 years ago.[20] The principle of the treatment lies in the preparation of the nervous system for subsequent bromide medication by a preliminary administration of opium. One of the preparations of opium, preferably the extract, is given for a period of six weeks in increasing doses up to 15 grains per diem, when it is suddenly stopped and large doses of bromide salt, from 90 to 120 grains, are substituted, this large dose being gradually diminished until about 30 grains are taken daily. The most favourable cases for its administration are young epileptics before or about puberty and epilepsy in the early stages. Confirmed epileptics and those with pronounced psychical degeneration are not materially benefited. Some authors speak very highly of the method, more especially Binswanger and his pupils, while others have not found its advantages outweigh its dangers. My own experience of the method has been limited and not satisfactory.

Various forms of *organo-therapy* have been suggested and tried in epilepsy. Of these thyroid administration was at one time strongly advocated, more with a view to counteract mental deterioration than as a subduer of convulsions. In a number of cases of confirmed epilepsy in which preparations of the thyroid gland were given over considerable periods, no appreciable result was detected either in the mental condition or in the frequency or severity of the fits. The administration of cerebrin also did not lead to any results which warranted its further or more protracted use.

[17] Krainsky: Abstract in Neurologisches Centralblatt, 1902, p. 16.

[18] Pugh: Brain, 1902, p. 100.

[19] Laudenheimer, referred to in Binswanger, op. cit.

[20] Flechsig: Neurologisches Centralblatt, 1893, p. 229.

The observation that a large and persistent thymus gland is found in cases of epilepsy in young persons has led to the view that the secretion of this gland may have some influence in the production of epileptic seizures, a view which appears to have some corroboration in the fact that the administration of preparations of this gland have materially aggravated the condition [21]

"*Salt starvation*"—Of the several forms of diet recommended in epilepsy I have found that of salt starvation or "dechloridation" the most satisfactory The suggestion of substituting the salts of chlorine by the bromide preparations is due to Toulouse and Richet, who recommended a diet in which the total quantity of sodium chloride per diem was limited to one or two grammes It was thought that by diminishing the chlorides in the food the bromides might be given in smaller doses and various writers have found the method useful The dietary which has been found most serviceable consists of milk, fresh butter, eggs, fruit vegetables, and bread, all salt being as far as possible eliminated The general results which were observed from the administration of the saltless diet in a number of cases of confirmed epilepsy were briefly as follows [22] There are some cases in which the number of attacks is diminished during the continuance of the treatment and others in which the improvement has lasted after the diet has been stopped These are the cases in which the bromides are not well borne or are even deleterious The mental condition also has shown some improvement The chief disadvantage of the diet is its monotonous character, but as a relief to dyspeptic symptoms it has been found distinctly useful The chief feature of the method lies in the diminution of the bromide dose, from 20 to 30 grains of one of these salts at bedtime being sufficient

Immunisation (Ceni's method[23]) —The idea of rendering epileptics immune to their fits, either by the injection of blood serum from one epileptic to another or by reinjecting into patients the blood serum which had been previously withdrawn from them, is due to Ceni The theory upon which this method is based is determined by the belief in the existence of a toxic biochemical substance in the blood serum of epileptics From his experiments Ceni concluded that there are two active principles in the blood of epileptics, one circulating in a free state and possessing toxic properties the other in a latent state, having a stimulating action upon the elaboration of the toxic agents The practical utility of this method in the treatment of epilepsy, even in the hands of its originator, has not been sufficiently satisfactory as to render its application general, while later investigations, more especially at the hands of Sala and Rossi,[24] have failed to confirm the original results

In conclusion, I wish to emphasise the fact that the medicinal treatment of the convulsions forms only one item in the treatment of epilepsy To my mind the most satisfactory management of the disease is that which is carried out in special institutions or under the care of a well trained and sensible nurse attendant In this way only can the patient be guided along hygienic lines, in respect of the suitable quantity and quality of food, the proper allotment of work and rest, and the carrying out of those physical exercises consistent with the malady Epileptics suffer notoriously from lowered vitality and sluggish circulation in the extremities for which warm baths, spinal douches, and massage are important remedial agents In the treatment of epilepsy, therefore, there has ever to be kept in mind the persistent character of the malady and the tendency towards mental deterioration As important as therapeutic remedies are congenial employment, hygienic modes of life and suitable amusements

DRAINAGE OF PLYMOUTH —A Local Government Board inquiry was held at Plymouth on Feb 28th respecting the application of the town council to borrow £65,000 for the purpose of main sewerage This sum, together with the amounts that have been sanctioned on previous occasions, makes a total of £210 800 which has been required for the scheme It was originally estimated that the work could be completed for £100,000

MENTAL FACULTY IN THE CHILD. ITS GROWTH AND CULTURE[1]

BY FRANCIS WARNER M D LOND , F R C P LOND ,
PHYSICIAN TO THE LONDON HOSPITAL, ETC

LOOKING at an infant or a young child we may observe the indications of mental faculty and study their growth and development in much the same way as we look at any other living creature Looking carefully at a healthy, strong, newly born infant we see *much spontaneous movement*, *the* fingers and the toes move separately, these movements do not appear to be stimulated through the senses and at this early stage they are not controlled by sight or by sound but appear to be quite irregular in their order This spontaneous movement, seen while the child is awake, is produced by the activity of groups of nerve cells in the brain, for these cells discharge nerve currents to the muscles and thus stimulate them to movement We see the spontaneous movements in the *child* and we *infer that the nerve cells of the brain are* acting spontaneously This mode of brain action is analogous *to what occurs in the cellular stem of young seedlings In* these the unequal swelling and growth of the vegetable cells on successive sides of the stem produce the circumnutatory movements which subsequently become adapted by light, gravitation, or other form of stimulus into definite controlled movements, such as turning towards the light, *climbing, &c, and the movements* produced in this way from the 'spontaneity' of the living plant when controlled by external stimuli are of great importance in its life-history This spontaneity of the nerve centres of the brain is temporarily lost when the child is ill and it is not seen in the imbecile

When observing an infant four or five months old the sight of an object, such as a red ball, may temporarily arrest the spontaneous movements, and this may by followed by the turning of the head, the eyes, and the hands in the direction of the object seen or the sound heard It will probably be said that this is a sign of 'attention" in the child and it may correctly be called a mental act, perhaps this is the earliest sign observable that can be so called I may here remark that all visible indications of mental action are by movement or the results of movement, whether in action speech, or writing At this early stage of development sight or sound may so affect the brain centres as to arrest momentarily their spontaneous motor action, a pause in movement is seen lasting but the fraction of a minute after which the infant fingers move again in a new and coordinated manner The new action which is seen after this pause is clearly the result of control of the brain centres during the temporary absence of movement and is a further act of 'attention" These facts suggest the hypothesis that during the pause in a sensory stimulus functional brain centres preparing them then, corresponds to the second stage of mental action which may be subsequently expressed in some mode of response

We have seen that two phenomena are characteristic of the earlier workings of the brain—namely, spontaneity and controllability, by the interaction of these two natural conditions it is possible to coordinate the brain cells through the senses by suitable methods of training As the child grows older some attempt must be made to cultivate the mental faculty and to control his playfulness, in part at least, for a few moments while trying to produce a new impression, but it is harmful to suppress or to destroy all spontaneity of brain action and movement After frequent repetition some *impressions are retained This leads us to* consider the means at our disposal in producing impressions by brain training as growth proceeds At an early school age, say in the kindergarten, we proceed, stage by stage, to develop such elementary mental impressions as it is intended to employ in subsequent teaching It will be useful to consider briefly, though with careful attention the nature of brain impressions and the means of producing them with accuracy *in a* well planned method of education Two points must be insisted on first, a certain length of time is required for the production of a new impression in the growth was not cut so as to afford microscopic evidence, but it is most suggestive and interesting. Personally I am now advising the trial of this violet treatment in all cases of undoubted cancer which are inoperable and I will in due course publish the results. The publication of this case may possibly induce others to give a more serious trial to the so-called "violet cure" than I fancy it has hitherto received.

Exeter.

TWO CASES OF POISONING FROM THE EXTERNAL APPLICATION OF BELLADONNA OR ATROPINE.

By VALENTINE MATTHEWS, M.R.C.S. ENG., L.S.A.,

SENIOR SURGEON TO THE WESTMINSTER GENERAL DISPENSARY.

IN the first of the cases now to be described the patient was a man, aged 53 years, who suffered from lumbago for the relief of which he applied to his loins, before going to bed, a belladonna plaster, measuring eight inches by five inches, made by a well-known firm. On waking in the morning he was confused in his ideas and complained of dryness of the throat and considerable thirst. When seen by me about midday his pupils were much dilated and his fauces were dry and red. He talked excitedly but quite coherently, saying that it was only by a considerable effort that he was able to restrain himself from talking nonsense. He had removed the plaster at the commencement of the symptoms, remembering, as he informed me subsequently, that he had on one occasion previously suffered in the same way from a similar application. He had, before using the plaster, rubbed himself with some liniment, but there was no redness or abrasion of the skin when I saw him. The symptoms, with the exception of the dilatation of the pupils which remained for a day or two, subsided by the end of the day.

The second patient was a man, aged 63 years, who suffered from chronic eczema of the nates and applied some ointment containing four grains of sulphate of atropine in the ounce once before going to bed and once again during the night. Next morning he complained of dryness of the throat and great thirst and had a frequent desire to micturate. He consulted me, complaining of these symptoms and also of much pain and discomfort in the lower part of the abdomen. He was voluble and excited, the pupils were somewhat dilated, the fauces were dry and beefy looking, and the bladder was much distended. Emptying the bladder by means of a catheter relieved the abdominal pain. The symptoms in this case also subsided by the evening but there was a frequent desire to micturate for some hours after the bladder was emptied.

The remedy in each of these cases was self prescribed.

Suffolk-street, Pall-mall, S.W.

A CASE OF COUGH DUE TO INTESTINAL WORMS

By HERBERT C. P. MASSER, M.R.C.S. ENG., L.S.A.

THE following case may be of interest in view of the recent accounts in THE LANCET of similar instances.

A patient under my care, a woman, aged 87 years, suffered every night from intense paroxysmal cough for which I could in no way account. One morning on my visit I was shown a large specimen of ascaris lumbricoides which had travelled upwards through the naso-pharynx and was pulled out of the nose by her night attendant. After this all cough ceased. Santonin was given but no further worms were obtained.

Longford, Coventry.

ROYAL NATIONAL PENSION FUND FOR NURSES.—At the annual meeting of this society, held on March 9th last, Sir Henry Burdett, K.C.B., deputy chairman, presided and moved the adoption of the report which stated the year 1904 to be remarkable as having witnessed the issue of an exceptionally large number of pension policies, the total being 1185 as against 953 in 1903. The annuities falling due showed satisfactory progress and at the December quarter of the year these were being paid at the rate of over £12,000 per annum under 818 policies. The usefulness of the sickness branch was again exemplified by the fact that a sum of £1651 was distributed in sick pay during the year. The total funds increased during the year from £820,792 to £910,525.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on the Subsequent Course and Later History of Cases operated on for Appendicitis.

AN adjourned meeting of this society was held on March 14th, Sir R. DOUGLAS POWELL, the President, being in the chair.

Mr. HARRISON CRIPPS said that in dealing with the treatment of an acute attack of appendicitis it was necessary to consider the cause of these acute fulminating attacks. It was certain that some of them arose from ulceration and consecutive inflammation produced by a concretion, for the offending body was not uncommonly found *flagrante delicto* in the accumulated pus. But there was another and not infrequent cause to which pathologists had paid insufficient attention. This cause was inflammation or gangrene produced by a corkscrew-twist in the mesenteric attachment of the appendix giving rise to strangulation, a condition exactly similar to that which is seen in cases of twisted ovarian tumour. The clinical features of the onset and the condition found on operation were analogous. In both cases the onset of the attack was very sudden and was frequently described as a strain during some sudden exertion. The mechanism of the twist at the base could be clearly seen but in an extremely short time the twisted pedicle became so disguised by adhesion or inflammation that it could only be made out by subsequent careful dissection. No surgeon accustomed to operating on the appendix could fail to have been struck with the extraordinary position and distortion of the organ often disclosed. The appendix was often tucked away in the most extraordinary manner apparently beneath the cæcum, and when so discovered it was no longer a straight tube but acutely bent, so that the lower half lay parallel with the upper. In this position it might be only found and exposed after dissecting through what seemed to be dense adhesions and when discovered it was dark and swollen and not infrequently gangrenous. The explanation of the sudden attack in these cases and the distortion found could only be accounted for by a volvulus or twist in the mesenteric attachment and what appeared to be dense adhesions cut through before exposing the appendix was the folded and twisted mesentery, while the twist completely explained the doubling of the appendix on itself. The true cause of the trouble, however, was shown by the doubled-up, distorted, and often gangrenous appendix hidden away in the twisted mesentery. Since his attention had been directed to these cases he had twice had an opportunity of actually verifying and demonstrating the twist when operating. One was the case of a young man who, whilst at stool, was seized with violent pain in the right inguinal region followed by vomiting. The pain was very severe for an hour or so and then almost suddenly ceased. When the patient was seen the following day he was apparently perfectly well and with the exception of a little tenderness nothing could be found amiss. Six months later, when practising a young horse over some hurdles, he had an exactly similar attack which he described as having "sprained his groin." However, unlike the first attack, the pain and sickness continued and when seen on the third day he was in the midst of a typical and acute attack of appendicitis. An operation was at once performed and it was found that the neighbouring structures were already slightly glued together. The appendix was found with difficulty, being drawn down and doubled on itself and concealed by what appeared to be a folding over of the mesentery and this was partly cut through, believing the fold to be only an old adhesion. Mr. Cripps then referred to a similar case in which a twist of a turn and a half in the mesentery had resulted in a complete doubling of the appendix. The appendix in this case was obvious directly the abdomen was opened; it was superficial and completely doubled up by a corkscrew twist of its mesentery. It was as large as the little finger, being in a swollen and œdematous condition. The condition was so obvious and the adhesion was so slight that the volvulus was readily untwisted and the swollen appendix, previously doubled up, came out straight and was nearly four inches in length. The discussion last week at this society, together with the invaluable records of cases furnished, demonstrated beyond doubt what had already been generally admitted, that when appendicectomy was done for recurrent attacks during a quiescent period it was one of the safest and most successful operations in surgery, while, on the other hand, the same statistics showed the great danger there was in the cases that had gone on to suppuration. He believed in evacuating the matter by a full-length incision and cautious dissection. After gently washing out the pus if the appendix could be seen or felt it should be removed with as little disturbance of the parts as possible. If, on the other hand, the appendix or its remains could only be removed by [illegible] nsive separation of [illegible] contaminating the [illegible] be satisfied with a good gauze drain, only closing the angles of the wound. In conclusion Mr. Cripps wished, without hesitation, to endorse the views of Mr. Pearce Gould. It being universally admitted that the presence of suppuration or sloughing enormously added to the risk of the patient, why then wait between the onset of an attack until this condition was established?

Dr. S. WEST said that to estimate the facts correctly the experience of both physicians and surgeons was necessary and that each of them looked at the subject from different points of view. The physician was impressed by the number of cases that recovered without operation and the surgeon by the success which attended operation. It was not a safe assumption to make that the appendix was an obsolete structure and useless to the body. For all they knew the contrary might be the case. The increase in appendicitis of recent years was rather apparent than real and was explained largely by the increased number of cases operated on in the quiescent stage. To appraise the statistics of operation at their true value the statistics of appendicitis without operation were required for comparison. Not many statistics were available. Taking Hawkins's figures as a basis it appeared that 72 per cent. of the cases of acute appendicitis recovered without any operation, that of the remainder 13 per cent. had general peritonitis of whom most died whether operated on or not, and 15 per cent. ended in suppuration of whom about 4 per cent. died. The total mortality for all cases together was 14 per cent. Fitz made it 11 per cent. If the cases of general peritonitis were excluded the mortality rate with the minimum of surgery was under 5 per cent. If this were the truth or anywhere near the truth it should make them pause before recommending operation in all cases indiscriminately. Dr. West summed up his conclusions as follows. 1. The great majority of all case[illegible] without operation. [illegible] on in the quiescen[illegible] 3. Whenever suppu[illegible] should be performed at once. 4. Even perforation cases might be less fatal if operated on earlier. 5. The risk of perforation was exaggerated. 6. The opening of the abdomen was not a trifling procedure but introduced risks of its own. 7. Each case must be considered on its own merits and dealt with accordingly. 8. The success of operation largely depended upon the skill of the operator, so that a personal factor entered into the results which could not be allowed for in general statistics.

Mr. W. BRUCE CLARKE said that most speakers had divided [illegible] There [illegible] dealing [illegible] cases, [illegible] tly due to infection of the peritoneum, and he would not in such cases make any endeavour to find and to remove the appendix unless it was easily seen or felt. He referred to two very similar cases, one in which the abscess was opened and the appendix not removed and a second in which the appendix was removed. The first made a good recovery but the second died. He then referred to the condition of the appendix removed in some 200 cases. In 191 the epithelium was denuded and opened a path for septic absorption, in two there were tuberculous ulcers, whilst in the remaining seven no lesion was found. Of these seven cases five had been lost sight of, but in the remaining two one had subsequently had a renal calculus removed and the other a gall-stone. In these cases it was probable that an error of diagnosis had been made in the nature of the attack. He referred to another case in which a patient had had the appendix removed and yet suffered from recurrent attacks of "appendicitis." The abdomen was opened and an ileo-colic intussusception was [illegible] the other tables went back for so many years that the objection might be raised that all sorts of improvements had been introduced in the meantime. It seemed to him that the registrars would have placed the present state of affairs in clearer relief if they had confined themselves to recent years during which treatment had been influenced by various modifications of older methods. His table showed what had happened when the operation had been carried out immediately and the appendix removed in all cases. He thought that an absolute uncertainty prevailed as regarded prognosis in any individual case and no additional experience afforded him any added power of making one. A prognosis resting on statistics gave cold comfort to the individual when he could be well assured that he might not form one of the unfortunate minority.

Mr. J. D. MALCOLM gave his support to the view that early diagnosis and early treatment should be aimed at with a view to the prevention of septic complications. He related a case in which after 30 hours of very insidious symptoms a [illegible] which, however, was not shut off from the general sac of the peritoneum by adhesions. At a little distance the serous membrane appeared healthy but the intestines were greatly distended. He said that an inflammation terminating in sloughing was a sthenic process accompanied by a quick pulse, high temperature, hot dry skin, tenderness in the focus of infection, with great vascularity and œdematous swelling around it. Moreover, these symptoms progressed in severity for about three days before they terminated i[illegible] gangrenous [illegible] of the whole [illegible] the onset of [illegible] could not [illegible] that the gangrene occurred spontaneously and painlessly. It was pointed out that a similar process, without pain or symptoms, sometimes occurred in the wall of an ovarian tumour and in some cases of senile gangrene in the stomach and in the duodenum. He thought that the resemblance which had been noted between the appendix and the digestive organs in their structure and functions might be extended to their pathology, for in both there seemed to be a liability to a spontaneous, localised, painless, non-inflammatory gangrene which in both cases might be in single patches or multiple. Such a gangrene, when the slough did not separate, would give rise to a filtration of infective material through the sloughs and a consequent development of an asthenic peritonitis, causing death later by paralysis of the intestine, the symptoms at first indicating little danger. It was suggested that a localised spontaneous gangrene, if accompanied by pressure within the walls of the appendix, would very readily give [illegible] part and so some cases of [illegible] plained. Case No. 190 in [illegible] a gangrenous patch was found and pus in the pelvis and iliac fossa, was a good illustration of this condition. It was argued that immediate operation was as necessary in such cases as in those of perforating gastric [illegible] be equally goo[illegible] was, however, [illegible] necessary to ope[illegible] if those of spontaneous gangrene were to be saved. This plan was therefore considered advisable unless such early operations were prejudicial in other cases. It was urged that a true inflammation of the appendix always began in the mucous membrane, so that an early operation would insure a complete removal of the source of mischief. By delaying it was possible to save many patients from an operation but they might be saved only to become victims of dangerous septic complications, and if the surgeon waited until an operation was absolutely necessary it would have to be undertaken at the worst possible time, that is, when the ill-effects of the initial inflammation had fully developed.

It was considered safe to leave only those cases in which the patient was already recovering when first seen.

Mr. F. C. **WALLIS** said he would refer but to two points which had not been touched upon during the discussion. The first was the condition of the omentum in cases of acute appendicitis. He mentioned the case of a boy operated on for appendicitis in whom the omentum was infiltrated but not adherent. Three weeks after the operation symptoms of partial obstruction were present. The abdomen was opened and it was found that the small intestine was adherent to the omentum in two places. Two methods of treatment were possible in such a case, one to anchor the omentum and the other to remove it, and he was in favour of the second mode of treatment. The second point to which he referred was a protest against allowing patients to get up on the tenth or fourteenth day after the appendix had been removed. He considered that considerable risks were run by allowing patients to get up at so early a period after operation.

Dr. G. **NEWTON PITT** said that he had come to the conclusion that appendicitis had become more common. A marked increase occurred during 1889-90 and was coincident with the prevalence of influenza. He was of opinion that there was both an increase in the incidence and in the mortality of the disease.

The **PRESIDENT** regretted that Sir Frederick Treves was prevented from attending to conclude the discussion. He thought all would agree that that debate had been of extreme value. The subject of it had ripened through many years of experience, discussion, and criticism since it was first propounded at that society by Sir Frederick Treves in 1887, and it was particularly appropriate therefore that he should have introduced and reviewed it on this occasion. It must have been gratifying to him and to many other surgeons, most of whom had spoken in that debate, to watch the development of this domain of surgery to its present state of completeness. The great value of a discussion such as they had had, lasting through three prolonged and well-attended meetings, was that it had, for that time at least, concentrated the attention of both surgeons and physicians upon one particular problem in this case as to the best way of rendering the results of operations for appendicitis most satisfactory and of avoiding untoward complications. Many minds would have been settled as to the best modes of procedure, many points decided in the course of the debate, and by the large statistical experience with which it had been enriched. 1. One point, for instance, insisted upon by Sir Frederick Treves and strongly advocated by Mr. Pearce Gould, Sir William Bennett, Mr. Cripps, and Mr. Bruce Clarke, was that in cases of perityphlitic abscess it was best, as a rule, not to try to remove the appendix when imbedded, as it generally was, in entangled adhesions. 2. Another point which seemed to come out very strongly in the debate, and which was referred to by Sir Frederick Treves and alluded to by Dr. H. P. Hawkins and Mr. W. H. Battle, was the fact that failures and subsequent complication of the operation were sometimes attributable to its not having been adequately performed—i.e., to the appendix not having been excised from its very origin at the cæcum but only a portion cut off—and that this incompleteness of the operation was not infrequently due to the cæcal end of the appendix being partially invaginated. 3. Then, again, there was the very difficult question which had been touched upon by more than one speaker—viz., when to operate—and this was a question which was also of great interest and importance to the physician who otherwise was perhaps more concerned with the conditions which led up to appendicitis which did not come within the scope of the debate. When the diagnosis of perityphlitic abscess had been arrived at of course the operation practically immediately followed. Mr. Cripps would not wait for abscess but would advise operation in the earlier stage of appendicitis. But great emphasis had rightly been laid by many speakers, especially by Mr. Pearce Gould, Mr. G. R. Turner, and Mr. H. F. Waterhouse, upon the importance of anticipating abscess by dealing with the appendix in what was called the quiescent period of appendicitis. This view must, of course, be guarded by great care in diagnosis, for whilst, on the one hand, if diseased appendices were allowed to remain there was the risk at any moment of abscess with general peritonitis, with the result of raising the mortality of operative interference to about 25 per cent. instead of 2 per cent. or less for the simple operation; on the other hand, healthy appendices were sometimes removed, leaving behind the malady from which the patient had been promised relief. The danger must be recognised that the operation might be too lightly undertaken and might become too much of a routine practice and not sufficiently safeguarded by careful and accurate diagnosis. 4. Future complications in quiescent cases might be sometimes avoided by a careful preparation of the patient for a few days before the operation. 5. The society was especially indebted to Mr. Lockwood for his most valuable contribution to the debate by illustrating so clearly on the screen those points in the pathology of diseased appendices which were so intimately concerned with the future of the cases operated on. 6. Another point of great importance to the future comfort of the patient was touched upon by several speakers—viz., especially in cases requiring large incisions, the avoidance as much as possible in the first incisions of cutting across muscular fibre, the importance of separating rather than dividing the muscle with the view of obviating ventral hernia and the necessity afterwards of using a large and cumbersome truss. He could not let that opportunity pass without offering the sincere thanks of the society to those gentlemen who had taken part in the debate, and especially to those—Mr. Hugh Lett, Mr. W. H. Battle, Mr. G. E. Gask, Mr. A. Baldwin, Mr. W. G. Spencer, Mr. Barling, Mr. C. B. Lockwood, Dr. Lawrence Jones, Dr. H. P. Hawkins, Mr. H. S. Clogg, and Mr. H. A. T. Fairbank—who had at great labour prepared the statistics of some thousands of cases which had been laid before the society.

MEDICAL SOCIETY OF LONDON.

Carcinoma.

A MEETING of this society was held on March 13th, Mr. **JOHN LANGTON**, the President, being in the chair.

Dr. E. F. **BASHFORD** read a paper on Carcinoma based on researches made under the auspices of the Imperial Cancer Research Fund. He said that he proposed to confine his remarks to the "growth of cancer" and emphasised the fundamental importance of the study of its process of growth as distinct from its genesis. It was, in his view, the only effective method by which progress could be made in the solution of the problems as to the nature and the origin of cancer. He then gave some account of the work which had been accomplished by means of comparative and experimental methods, exhibiting a large number of lantern slides in illustration of various points of importance. He defined cancer as a malignant new growth. Many of the recent hypotheses enunciated to explain cancer had started with a theory of origin but failed to explain how the actual cell multiplication had been maintained in the gradual increase of the tumours.

PATHOLOGICAL SOCIETY OF LONDON.

Recent Work on Proteid Chemistry and Proteid Diet.

A MEETING of this society was held on March 7th, Dr. W. D. **HALLIBURTON** being in the chair.

Dr. **HALLIBURTON** read a paper on Recent Work on Proteid Chemistry and Proteid Diet. The paper, he said, was the outcome of a request from certain members of the society that he should lay before them the results of recent progress in connexion with the chemistry and the dietetic value of the proteids. In the time at his disposal he was only able to deal with this large and important question in its main features. The doctrine of Kühne that the albuminous molecule consisted of hemi- and anti-complexes united together had been abandoned. With the disappearance of that conception interest centred around the final decomposition products such as were obtainable as the result of prolonged proteolysis. Before a synthesis was possible a correct knowledge of these cleavage products was a preliminary necessity. These might be classified into the mono-amino acids like leucine and glycine, the diamino acids or hexone bases, the aromatic amino acids like tyrosine and tryptophane, members of the pyrrimidin and pyrrolidine groups, the sulphur-containing substance cystin, and ammonia. Particular attention was directed to the groups of amino acids called polypeptides which occurred as an intermediate stage in proteolysis between the peptones and the final products; and the fact that Emil Fischer had synthesised some of these was an indication that such work might culminate in the actual synthesis of the proteid molecule. In connexion with proteid absorption the trend of recent research was to show that a much more complete proteolysis occurred in the alimentary canal than was formerly supposed to be the case. The tissue proteids must therefore be constructed from the simple cleavage products and thus proteids were brought into line with fats and carbohydrates. This new theory assumed a complete breakdown of the foodstuffs previously to their being built up within the living tissue. It was thus less difficult to understand how the living organism could construct from the fragments the tissues peculiar to itself and maintain its chemical integrity although the food taken might vary widely in composition. If, however, foreign proteids were introduced directly into the blood stream they appeared to be retained largely in the body and if they were really utilised and preliminary cleavage was necessary, this must be accomplished by the tissue erepsins and similar intracellular enzymes. The activity now manifested by so many workers on the subject of autolysis was warranted by the importance of the subject. The part played by the tissue enzymes during life could only be elucidated by allowing them full scope after death. The discovery of the urea-forming ferment arginase had already been one important outcome of such study. Dr. Halliburton concluded his paper by a reference to the work of Chittenden on the "Physiological Economy in Nutrition" and showed that it was possible that our views concerning what constituted a normal dietary and a normal urine might need revision. Chittenden and his co-workers lived for prolonged periods on diets in which the amount of proteid was reduced to one half of what was laid down in the accepted Voit standard. This they did without apparent detriment to health and maintained their nitrogenous equilibrium. Whether such persons had the reserve force to withstand disease and severe privation must be left to the future. The matter was an important one for the economist as well as for the physiologist and pathologist. The work might also modify modern ideas regarding the feeding of infants and invalids.

Dr. R. HUTCHISON was glad that Dr. Halliburton had thrown out some warning against a too easy acceptance of the views put forward by Chittenden. The questions raised were difficult and involved other considerations beyond the establishment of nitrogenous equilibrium. Proteids had other uses in the economy of the body both in the direction of resistance against disease and as a possible source of stimulation of activity. The points under discussion could not be settled by experiments such as those of Chittenden and it was noticeable that diets all the world over showed a close approximation to the Voit standard.

Dr. E. H. STARLING said that in considering the total amount of nitrogen necessary for the adult man it was advisable to take into account two forms of metabolism—the [illegible] the energy metabolism. In the [illegible] be replaced by any other food and [illegible] a high nitrogen value was necessary for infants and for invalids; in the second the proteid was only of service in proportion to its heat value and could be replaced by the fats and carbohydrates. Chittenden had not taken into account the results of overstrain and the value of a highly nitrogenous diet in dealing with that condition.

Dr. C. G. SELIGMANN referred to the natives of New Guinea as examples of a race subsisting on food of low nitrogenous value. He had found that they lacked stamina and compared unfavourably in that respect with rice-eating races.

Dr. C. J. MARTIN believed that the ordinary diet containing 17 grammes of nitrogen was too high and pointed to the fact that a considerable portion was immediately thrown out in the form of urea. A large number of people could do perfectly well on ten grammes and the additional amount really came into the same category as alcohol and tobacco. The defect in the British army ration was the excess of nitrogen and insufficiency of calories.

Dr. W. S. LAZARUS-BARLOW referred to the specific precipitin reaction of proteids and its remarkable value in the differentiation of varieties which were otherwise identical.

CLINICAL SOCIETY OF LONDON.

Discussion on Rheumatoid Arthritis, Arthritis Deformans, and their Allies.

A MEETING of this society was held on March 10th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. W. HALE WHITE made a communication on Acute Rheumatoid Arthritis, with epidiascope demonstration. He remarked that among the diseases which were often grouped together under the names rheumatoid arthritis, osteo-arthritis, arthritis deformans, and chronic articular rheumatism there was one which should be sharply separated off as a distinct disease and which might be designated acute rheumatoid arthritis. It had, he believed, the following characteristics. It was usually met with in women whose age was most often about 20 years; the disease began, or was at any rate soon found, most prominently in the proximal phalangeal joints and in the wrists; it was markedly symmetrical in the two hands; the swelling was considerable and extended beyond the joints, so that there was a well-marked fusiform or generalised swelling about the affected joints; sometimes a creaking might be felt, due apparently to thickening of the synovial membrane. In the course of a very few weeks most of the joints in the body were swollen and painful, so that the patient was soon bedridden and unable to move fingers, thumbs, wrists, elbows, shoulders, and the corresponding joints of the lower extremity. The joints of the spine were often affected so that turning in bed was difficult and painful; the temporo-maxillary joint was frequently implicated and mastication was consequently difficult. Muscular wasting was so very rapid that it was clearly an extreme degree of genuine arthritic atrophy and not dependent on disuse; the wasting was especially seen in the hand and the forearm, but in a bad case it was almost universal. The temperature was often raised, mostly in the evening, to a point between 100° and 102° F. The hands and the feet were often covered with sweat while the rest of the body was quite dry; the patient was pale and the pulse increased in frequency out of proportion to, and apart from, pyrexia, although neither from the history nor from the examination of the heart was there any evidence to connect the disease with rheumatic fever. Sometimes a number of brown spots like large dark freckles appeared on the face, the body, and the limbs. After two, three, four, or even six weeks the temperature slowly returned to normal and the rate of the pulse diminished, but more slowly than the temperature; the sweating of the hands and the feet lessened, the pain passed away, but much immobility and some swelling around the joints remained. The patient was liable to fresh attacks which exactly resembled the first and resulted in fresh swelling of, and around, the already fixed joints. After the acute stage had subsided the sufferer by no means recovered the use of her joints, for the swelling of the synovial membrane and the soft tissues around led to great immobility and much of the muscular atrophy remained; the patient was hence often a chronic invalid. In this respect, as well as in many others, the disease presented a striking contrast to rheumatic fever. Careful manual examination during life, even in cases which had lasted many years, failed to reveal any lipping or bony outgrowths in connexion with the joints. The deformity appeared to be entirely due to effusion into the joint and swelling of the tissues around. Radiographic examination confirmed this view. As a rule the attacks diminished in severity as time went on and ultimately the patient might only suffer from the deformities resulting from previous attacks. Dr. Hale White next described the histology of the disease and showed that it undoubtedly originated in the synovial membrane and the tissues around the joint and that no changes occurred in the bone or the cartilage except such as were produced by pressure of thickened synovial fringes. [illegible] of a woman, aged 25 years, and [illegible] passive movements in order to [illegible] by means of lantern slides that the bones [illegible] the x rays. Lastly, he discuss[illegible] diseases, maintaining that it was a distinct morbid condition for which the most convenient appellation would be acute rheumatoid arthritis.

Dr. BERTRAM L. ABRAHAMS read a paper on Arthritis Deformans and its Allies. The expression "arthritis deformans" was selected as the least unscientific of the many names—Purnam in his recent monograph had quoted 21—for the disease and that in most general use on the continent and in America. There were, in Dr. Abrahams's [illegible]

[illegible] phatic glands. At the other end of the scale was [illegible] osteo-arthritis which was a degenerative process which might come on as the terminal phase of arthritis deformans, or quite apart from it as a senile change in normal joints or in those already crippled by true rheumatism. The two remaining affections—acute and chronic arthritis deformans—were, it was suggested, different forms of the same malady which was in all probability of an infective or at any rate a toxæmic nature. In the acute type, which occurred for the most part in young women, the poison was in such considerable amount that a large number of joints were, so to speak, flooded with it and simultaneously affected. In the chronic form, a multiple arthritis in middle-aged persons, the intoxication was less severe but more prolonged, so that the morbid changes were more in the nature of degeneration than of inflammation and the joints were picked out in a fairly definite order. At the same time, as might be expected, much of the brunt of the disease fell upon the nervous system. That the two types merged into one another was further indicated by the number of intermediate forms which were met with. Skiagrams and photographs were shown of the following conditions: gonorrhœal arthritis, Charcot's joint disease, acute arthritis deformans, and chronic arthritis deformans.

Dr. F. S. TOOGOOD was familiar in infirmary practice with Dr. Hale White's acute cases but thought that the same disease occurred also in men. He remarked on the difficulty in diagnosis between these cases and gout. In his experience drugs were of no avail in the condition, though a proteid diet sometimes did good. The senile form of arthritis deformans in which fibrillation and other degenerative changes occurred in the cartilages was to be found post mortem in greater or less degree in nearly all persons over 60 years of age. That morning he had examined the joints—specimens of which he exhibited—of a patient which were of this nature.

Dr. A. E. GARROD, following the classification adopted by Dr. Abrahams in his paper, referred to the disease met with in children, the relation of which to acute rheumatoid arthritis he regarded as an open question; in his (Dr. Garrod's) experience the enlargement of the spleen and the lymphatic glands was by no means constant, but the fatal tendency of the disease of children was in marked contrast to what was seen in the malady in adults. He was convinced that the cases met with in middle life were examples of two, if not of three, distinct diseases. In one class of cases, which might be called rheumatoid arthritis, the fusiform swelling around the joints, the special implication of the interphalangeal joints of the first row, the rise of the temperature, and the rapid pulse were important characteristics. In the other disease, which might be designated multiple osteo-arthritis, the osteophytic enlargements, the absence of any obvious swelling of the joint capsules, and the special liability of the end joints of the fingers and carpo-metacarpal joints of the thumbs were conspicuous. Both diseases were apt to implicate the joints of the cervical spine and the jaw. It was important to realise that the former disease, whether acute, as in Dr. Hale White's cases, or more chronic, as it often was, was almost certainly infective and in time ran its course. He suggested that the name of rheumatoid arthritis should be limited to the former and that of multiple osteo-arthritis to the latter disease. The former was commoner in earlier life but might occur at any age; the latter was commoner in later life but might develop unusually early. The infection in the rheumatoid cases was very often a puerperal one, thus partly accounting for the greater frequency in women, though men were also attacked. Treatment was more efficacious in the osteo-arthritic cases. He was inclined to believe that there was a third and much rarer disease which included those cases in which without very conspicuous swelling of joints the muscular atrophy and contracture without resulting deformities were prominent features almost from the onset.

Dr. A. P. LUFF also thought that several different diseases had been included under the same name. He regarded rheumatoid arthritis, whether acute or chronic, as of infective origin. He believed strongly that the infection took place by the alimentary tract and was convinced of the high value of intestinal antiseptics, notably of carbonate of guaiacol. In the distribution of the lesions he remarked that the acute cases affected the proximal interphalangeal joints and the chronic the thumb joints. In the diagnosis between rheumatoid arthritis and gout there should not be much difficulty; the two most important points were the symmetry of the former and the sweating or clamminess of the palms and the soles. The cervical vertebræ and the temporo-maxillary joint were rarely affected in gout. He commented on the advances made of late years in the treatment of rheumatoid arthritis and advocated abundant nutriment. He did not think that the single-joint type of case was of infective origin but was a traumatic form of osteo-arthritis; monarticular rheumatoid arthritis was therefore a bad term.

Dr. PRESTON KING (Bath) remarked that Dr. J. K. Spender of Bath had first pointed out the rapid pulse, the sweating of the palms, and other characteristic features of the more acute forms of rheumatoid arthritis. He (Dr. King) did not think that the x rays were of any value in the diagnosis from gout and doubted whether increased transparency necessarily implied rarefied bone. That there was a strong nervous factor in the disease was undoubted; it was instanced by the muscular atrophy and the vaso-motor symptoms. He regarded the condition as a result of the action of the rheumatic virus on the nervous system.

M. BLANC (Aix-les-Bains) related two severe cases that had contracted diphtheria and had recovered from the joint disease after treatment by antitoxin. In ten cases he had used the same treatment and improvement had resulted but he had rarely had the opportunity of trying its effect apart from bath treatment. In regard to diagnosis the main difficulty was not in excluding gout but in distinguishing between rheumatoid arthritis and osteitis deformans.

Dr. W. EWART was of opinion that the toxic origin of these arthritic conditions was now established, though the number of such toxins was legion. The actual poison was more likely to be that secreted by microbes than the microbes themselves and might indeed be autotoxins. In this connexion he used the analogy of the joint changes seen in bronchiectasis. He was at present getting good results by varying the blood-supply to the part so as to produce alternate anæmia and hyperæmia.

Dr. R. LLEWELLYN JONES (Bath) saw very little difference between the acute and the chronic cases; the temperature ran a similar course in both. He found few cases free from nervous symptoms. He had also been struck by the segmental distribution of the lesions; thus the ring and the little fingers were usually affected together and the thumb and the index finger. He agreed with Dr. Luff as to the importance of gastro-intestinal troubles and cited cases of gastric ulcer followed by rheumatoid disease. He suggested an analogy with tetany and drew attention also to the frequency with which Graves's disease and rheumatoid arthritis were associated.

Dr. HALE WHITE, in reply, agreed that the condition which he had described was not rare in men. As regards the transparency of the ends of the bones and the fusiform shape of the swelling he recognised that both occurred in other conditions but as they were never absent in this disease their presence or absence was of importance in diagnosis. With regard to the grating observed by Dr. Garrod he acknowledged that destruction of the cartilage occurred, but emphasised the fact that it was in these cases always secondary to the synovial mischief. He was very sceptical as to the power of any drug to disinfect the alimentary canal.

Dr. ABRAHAMS, in reply, agreed with Dr. Luff as to the great value of guaiacol carbonate but could not attribute this to its antiseptic properties on the intestines, seeing that it was the only member of the group that possessed such beneficent effects. He was interested in M. Blanc's remarks on diphtheria antitoxin as ten years ago he had seen Dr. Sydney Ringer treat a case of gonorrhœal rheumatism with it. Dr. Ringer's favourite remedies for arthritic conditions were guaiacum and actæa racemosa.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on March 10th, Dr. William Alexander, the President, being in the chair.—Dr. Frederick Edge showed: (1) A specimen of Malignant Adenoma of the Fundus of a Uterus removed by the vagina from a patient, aged 62 years, suffering from sanious vaginal discharge for two years previously; and (2) a Malignant Tubo-ovarian Cyst from a patient, aged 44 years, who complained of a foreign body. The papillomatous growth commenced in the tube and did not involve the wall deeply.—Dr. Edge also read notes of a case of Severe Metrorrhagia where, after removal of the uterus, a submucous fibroid was found at the fundus with lengthening of the cavity for an inch, and exhibited a Uterus removed from a patient past the menopause for prolapse and ulceration of the vagina. In performing vaginal hysterectomy for prolapse he divided the posterior vaginal wall medially and after removing the uterus he sutured the recto vaginal fascia transversely which permitted complete closure of the anterior part of the wound with drainage of the pouch of Douglas from the lowest point without weakening the pelvic floor —Dr J Inglis Parsons then read a paper on the Choice of Treatment for Fibromyoma of the Uterus The question was discussed under seven headings 1 Tumours producing no symptoms *Operation was not considered justifiable in these* cases 2 Small tumours causing severe menorrhagia without pressure symptoms In 95 per cent electricity would diminish the hæmorrhage and ought to be tried before operation 3 Small tumours producing pressure symptoms with or without menorrhagia If the pressure was on the bladder operation was necessary myomectomy, hysterectomy or removal of the appendages 4 Uniform enlargement in shape resembling that of pregnancy at four to six months and causing pain and metrorrhagia Operation was recommended for this group because of the pressure symptoms but if declined electricity was of great value 5 Tumours forming a round mass confined to the pelvis and sometimes impacted should be operated on as soon as possible because of the pressure caused by them 6 Very large tumours filling the abdomen of the size of a full term pregnancy Hysterectomy was the only available treatment for these tumours 7 The relation of the menopause to fibroid tumours The menopause came on much later and as a rule the tumours ceased to grow and became smaller He gave notes of three cases treated by electricity which he had watched for 17, 14 and 9 years respectively through the menopause and which were doing well without operation —Dr J A Mansell Moullin said that the paper ignored the brilliant improvement in the results obtained by operation

during the last 15 years hought
be confined to the cases ir others
undoubtedly demanded ugl ton
Jones had tried electricity enrodt
had given it up Every case should be dealt with according to its special features and complications —Dr J Macpherson Lawrie protested against the sweeping disapproval of electrical treatment of myoma He had known it to be of good service in many cases diminishing hæmorrhage relieving pain and sometimes leading to shrinking of the tumour —The President thought that a patient ought not to be *informed of the presence of a tumour, the knowledge of* which would be a constant source of depression to her She should invariably be given medical treatment in the first place and the removal of the tumour should only be undertaken by the gynæcologist Any good effects of electricity were merely palliative and deferred but did not do away with the necessity for an operation He had found the results of the removal of -thy and in
the majority of ca e the best
operation though if he might
enucleate it —Dr Inglis Parsons in reply said that if as was sometimes possible the pelvic organs were restored to health by electrical treatment the patient would not be a chronic invalid, he had not found such treatment
render a subsequ

the President as to the removal of the appendages

LEEDS AND WEST RIDING MEDICO CHIRURGICAL SOCIETY —A meeting of this society was held on March 3rd Dr Adolph Bronner being in the chair —Dr E F Trevelyan described cases of Erb s Juvenile Dystrophy occurring in four well developed members of a family made up of father aged 49 years mother aged 36 years four sons aged respectively 18 17, 11 and two years and four daughters aged respectively 20, 15 13 and seven years The father, two sons aged respectively 18 and 11 years and the daughter aged 13 years were affected The chief characteristics of the disease in the father and two eldest children consisted in the winged and displaced scapulæ the wasted muscles of the upper arm (including the brachio radialis), lordosis and a slight waddle in the gait *The* volume of the deltoids was considerable Some unusual muscles were involved in both the father and the eldest son The son aged 11 years, showed only slight displacement of the scapulæ and some weakness of the muscles No hereditary or family factor could be ascertained in the father, in whom the disease commenced at the age of 18 years Dr Trevelyan then distinguished between the various types of progressive dystrophy and between the latter and amyotrophies of spinal cord and peripheral nerve origin The slow progress of the disease and its *temporary arrest were illustrated* by the case of the father who had been able to do manual work up to recently The disease apparently began in the elder son between the age of 12½ and 14 years while he was engaged in hard work in pushing trucks in a quarry The prognosis seemed to be unfavourable in his case as the disease was extending rather rapidly Reference was made to the supposed limited vitality of the muscles in progressive dystrophy and to certain developmental facts, such as the liability to variations in the muscles most often affected in this disease Repair seemed to be impossible in these cases and the most that could be hoped for was the arrest of the disease For this purpose the patient should live under the best hygienic conditions and perhaps massage and systematised exercise might also be useful —Dr Thomas Churton Dr A G Barrs and Dr T W Griffith discussed the paper —Dr Carlton Oldfield read a paper on a case of Vesicular Mole associated with Double Ovarian Cysts and followed by a Growth of Chorio epithelioma in the Uterus The patient was aged 22 years Two weeks after the date when she had expected to be confined she had a dribbling menstrual discharge for three months and then a severe hæmorrhage A vesicular mole was removed and the next *day the ovarian cysts were noticed* Five weeks later the cysts were removed and the body of the uterus was amputated a disc of growth of the size of a shilling being found in the muscular substance of the posterior uterine wall A week later the cervix uteri was removed through the vagina The patient made a rapid recovery and was well and free from recurrence 13 months afterwards Attention was drawn to the association of the three rare conditions—namely lutein ovarian cysts vesicular mole and chorio epithelioma—and quotations from the literature were given to show that chorio epithelioma was so often associated with the other conditions that there must be some causal relationship The theory put forward was that excessive lutein secretion from the lutein cystic ovaries was the cause of the excessive proliferation of the trophoblast resulting first in vesicular mole and then in chorio epithelioma —Professor A S F Grunbaum read a paper on Vaccines and Serums in Theory and Practice —Dr H J Clarke and Mr B G A Moynihan showed a patient upon whom Gastro enterostomy was performed five years ago —Mr L A Rowden showed a case of Lupus Vulgaris nearly healed under treatment by the x rays —Dr T Churton showed a man who suddenly became cyanosed while at work was bled to the amount of 40 *ounces and rapidly recovered —Other cases and specimens* were shown by Mr J Stewart Dr H Irving Dr J B Hellier Mr H Secker Walker Dr T Wardrop Griffith Mr S T Rowling Dr Alfred Mantle Mr Edward Ward and Mr R Lawford Knaggs

ULSTER MEDICAL SOCIETY —The seventh annual meeting of this society was held in the Pathological Laboratory of Queen s College Belfast on March 2nd Dr W Calwell, the President being in the chair Professor Johnson Symington and Dr H Hanna exhibited (1) a series of Young Temporal Bones showing the Develop*ment of the Air Cells*, (2) a *Female Pelvis* with Distended Rectum showing the spread of malignant disease from the uterus (3) a Skull to illustrate the Eruption of Teeth (4) Enlarged Photographs of the Internal Ear and Sections of the Medulla Oblongata, and (5) Drawings from Sections of the Brain —Professor T H Milroy *read a short paper on the Exchange of* Nutritive Material between Different Organs of the Body, as exemplified in the Spawning of Fish —Dr J A Milroy gave a Microscopic Demonstration of some Specimens illustrating the Structure of the Ductless Glands —Dr R A L Graham described a case of General Paralysis of the Insane with Meningomyelitis (illustrated by sections shown *by the lantern)* —Sir William Whitla showed a Tumour of the Brain (with sections) —Professor J W Byers showed (1) a Solid Tumour of the Ovary (section), (2) an Extra uterine Fœtation beautifully mounted to show the bones by *Dr* Marion B Andrews, (3) a specimen with an Ovarian Tumour on one side and on the other *a Tumour of* the Fallopian tube but distinct from the ovary probably tuberculous, (4) a New Pelvis for teaching purposes, and (5) a *series* of Plaster Casts of the Fœtal Head (natural and abnormal).—Dr. John Campbell exhibited: (1) a Kidney Tumour; (2) a mounted specimen of Cancer of the Sigmoid Flexure; and (3) a Uterus removed per vaginam (with section) of an adenomatous nature.—Professor J. A. Lindsay showed a large Aneurysm of the Aorta.—Mr. G. L. St. George described: (1) a Parotid Tumour (with section); and (2) an Axillary Tumour (with section).—Dr. H. L. McKisack showed a Ruptured Aneurysm of the Basilar Artery.—Mr. A. B. Mitchell exhibited (1) a Sarcoma of the Femur (with section); (2) a Hand and Arm showing a combination of Tubercle and Carcinoma (with section); and (3) a Carcinomatous Tumour of the Scalp (with section).—Mr. A. Fullerton showed (1) a Malignant Adenoma of the Breast (with section); (2) a Dermoid Cyst of the Neck (with section); (3) a Duct Cancer of the Breast (with section); and (4) a Stomach showing Gastric Ulcer with Erosion of the Pancreas (section of pancreas).—Dr. T. S. Kirk, exhibited specimens of: (1) Acute Suppurative Periostitis; (2) Ovarian Cyst; (3) Squamous Epithelioma of the Lower Jaw (with section), (4) Lymphosarcoma of rectum (with section); and (5) a Series of Prostates.—Dr. James Lynass exhibited: (1) Charts showing the Effects of the Serum Treatment of Erysipelas; and (2) Glandular Tumours removed from the Neck.—Dr. Marion Andrews showed: (1) an Abscess of the Ovary (with section); and (2) a series of Specimens Preserved and Mounted by the Kaiserling Method.—Dr. William Mair demonstrated certain recent Methods for distinguishing colonies of the bacillus coli and the bacillus typhosus.—Dr. Thomas Carnwath read a note on the Value of the Streptococcus as an Index of Sewage Contamination.—Dr. J. C. Rankin exhibited two interesting Skiagrams.—Dr. Thomas Houston and Dr. Rankin showed Preparations demonstrating that the Opsonic Power of the Serum is Destroyed by Heat at 60° C.—Dr. Houston also gave demonstrations of the Method of Preparing and Administering a Vaccine for the Treatment of Staphylococcic Lesions (A. E. Wright's method).

Manchester Medical Society.—A meeting of this society was held on March 1st, Mr. W. Thorburn, the President, being in the chair.—Dr. Joshua J. Cox showed an interesting case of a boy, aged nearly 11 years, with well-marked Achondroplasia, and weighing about 28 pounds. The differential signs between rickets, cretinism, and achondroplasia were pointed out and a series of skiagrams were on view of the bones in normal children, in a case of infantile myxœdema, and in achondroplasia. In the present case the stunting and deformity of the long bones, the "trident hand," the lordosis, and the immense development of the gluteal, the thigh, and the calf muscles were very noticeable. Dr. Cox pointed out the importance in obstetric practice of having careful pelvic measurements made in any case of pregnancy in which, owing to dwarfism with shortened extremities, slight achondroplasia with narrowing of the pelvis might be suspected.—Mr. E. Stanmore Bishop mentioned a case of Muco-colitis treated by Lavage through the Appendix. These cases usually occurred in women, in neurotic subjects, and were frequently complicated by some disease of the generative organs. After referring in detail to all the methods, medical and surgical, which had been adopted in their treatment he drew attention to a plan proposed by Dr. Weir of New York which utilised the appendix as a natural tube by means of which access might be obtained to the interior of the cæcum and thereby the entire large intestine might be flushed out. Details of the case were then given.—Dr. R. J. Ewart read a paper on Venesection, its Indications from a Physiological Standpoint, in which he showed the unsuitable character of the term "viscosity" as applied to blood. The blood met a much greater resistance in its passage through a capillary than would be the case with a homogeneous fluid, the disparity amounting to between four and five times. If it was desired to get the maximum number of bodies suspended in a fluid through a capillary with the minimum expenditure of energy a certain number must be present per cubic centimetre. This optimum depended on the size, shape, and specific gravity of the suspended bodies. The removal of blood from the vessels was always, even in very diverse conditions, followed by a fall in the number of corpuscles per unit of volume. A certain quantity of oxygen was an absolute necessity for tissue metabolism and this supply was the demarcating factor for the minimum rate of flow. Hence, therefore, variation in the number of corpuscles per unit of volume would render the blood mechanically inefficient as an oxygen vehicle. In disturbed conditions of the circulation, accompanied by anæmia, a hæmatinic course of treatment was more likely to be beneficial than attempts to stimulate the heart. If the number per unit of volume should rise venesection was strongly indicated. From a physiological standpoint the indication for venesection was an excessive relative number of corpuscles, provided that the circulation had sufficient power to make up the loss with lymph drawn from the tissue.—Dr. J. A. Knowles Renshaw showed a Radiogram of the Chest in a case of Aneurysm of the Arch of the Aorta.

West London Medico-Chirurgical Society.—A meeting of this society was held on March 3rd, Mr. C. M. Tuke, the President, being in the chair.—Dr. Alexander Morison read a paper on Boldness in Treatment of Certain Phases of Pneumonia. The principal points referred to by Dr. Morison were (1) the treatment of high temperature by the application of ice to the body or to the head alone; (2) the conservation and relief of the heart by frequent injections hypodermically of strychnine and the administration of turpentine internally; and (3) the relief of the heart by blood-letting.—Dr. G. A. Sutherland, in referring to the use of strychnine, said that as a rule insufficient doses were given and advised the drug to be used at frequent intervals and in large doses until the physiological effects were produced.—Dr. A. Elliot did not think energetic and bold measures for reduction of temperature should be used unless the temperature exceeded 104° or 105° F. and then he found that application of ice to the chest was as a rule badly borne and he recommended cold sponging as being preferable. Referring to blood-letting, Dr. Elliot considered that the amount of blood withdrawn was not of such great importance as the rapidity with which the loss of blood was effected.—Dr. Otto F. F. Grünbaum also advised non-interference with the temperature *per se*, unless it exceeded 104°.—Dr. Morison, in reply, agreed with Dr. Elliot that it was not so much the quantity of blood withdrawn as the rapidity with which it escaped which relieved the surcharged heart.—Mr. Cecil H. Leaf read a paper on the Clinical Causes of Cancer of the Breast in which he proved by a very complete table of statistics that not only one but many causes of cancer exist. The special points discussed by Mr. Leaf were (1) age; (2) state—married or single; (3) family history; (4) lactation; (5) previous diseases of the breast; (6) injuries; (7) corsets; (8) worry and anxiety; (9) residence; (10) diet—consumption of meat, salt, uncooked vegetables, &c., alcohol; and (11) miscellaneous—general health, occupation, and infection.—Dr. S. D. Clippingdale considered the coincidence of cancer with consumption to be of great clinical importance and he also drew attention to a paper published by himself in which he endeavoured to show that both these diseases in London were more common in the low-lying districts near the river, irrespectively of soil.—Mr. J. G. Pardoe wished to impress upon the members the importance of the infectivity of cancer and gave a practical illustration of the same.—Mr. F. Lawrance considered cancer to be, without doubt, hereditary and also possibly infectious.—Mr. Leaf made a few remarks in reply.

Clinical Society of Manchester.—A meeting of this society was held on Feb. 21st at the Palatine Hotel, Dr. E. S. Reynolds being in the chair.—Dr. Gordon W. Fitzgerald read a paper on Hæmorrhage in the First Three Months of Pregnancy, with Special Reference to Abortion. He said that the chief causes of hæmorrhage in early pregnancy were abortion, menstruation, ectopic pregnancy, hydatidiform degeneration of the chorion, and malignant disease of the cervix. Abortions were classified as either threatened or inevitable. Incomplete, complete, cervical, and missed abortions were all inevitable. Chief amongst the causes was endometritis which itself was generally due either (1) to conditions causing chronic congestion of the uterus or disease of the endometrium; or (2) to improper emptying of the uterus at a former confinement. Patients who have previously aborted should, apart from other treatment, observe great caution during the times that they would be "unwell" were they not pregnant. "Habit" was frequently cured by pushing mercury. The use of the pessary to retain a gravid uterus in position was sometimes dangerous. Threatened abortions were treated by opium in large doses and by rest. The indication in inevitable abortion was to empty the uterus and the sooner this was done the better. The blunt flushing curette would empty the uterus more safely and completely than any other means. Tents or rapid dilators might be needed to attain a sufficient dilatation of the cervix. After abortion the patient should be treated as after full-term delivery.

Therapeutical Society.—A meeting of this society was held on Feb. 21st, Mr. A. B. Day being in the chair.—Dr. T. E. B. Brown read a paper on Herbals and Herbaria, in which he described various old theories as to the action of plants as medicines and the necessity for accurate descriptions and pictures of medicinal plants; hence the origin of the science of botany and the formation of herbals. He spoke of Gerarde's, Tournefort's, and other herbals and read extracts of the use of sage and danger from the poison of toads if rue was not added; also of plants that improve the skin, such as arum, cyclamen, vervain, watercress, and white bryony. He described the use of black bryony root for contusions of the eye and of euphorbia juice to remove warts or hairs, or butterwort to turn the hairs yellow, and colocynth black, mentioning that more powerful remedies could be obtained from minerals but also more dangerous ones. He then described various methods of drying plants for herbaria and showed specimens prepared in 1770, and finished by quoting the familiar lines from Erasmus Darwin's "Loves of the Plants":—

> [illegible]

Afterwards there was an exhibition of Botanical and Therapeutical Appliances, in support of which the Society of Apothecaries of London showed a Herbarium made in 1770. —Mr. J. Bryant Sowerby of the Royal Botanic Society showed the original edition of Gerarde's Herbal and pictures of medicinal plants, Dr. Herbert French showed an early copy of Gerarde's Herbal, hand-painted, and two copies of [illegible] hod to Measure Blood [illegible] arious kinds of leucocytes [illegible] rpuscles; while Messrs. [illegible] Botanical Presses and Collecting Cases, Messrs. Watson and Sons exhibited an improved High-frequency Apparatus in action, an X Ray Tube for Alternating Currents, and other electrical apparatus, and Messrs. Burroughs and Wellcome showed a large number of chemical and botanical specimens.

Brighton and Sussex Medico-Chirurgical Society.—A meeting of this society was held on March 2nd, Mr. G. Morgan, the President, being in the chair.—Dr. E. F. Maynard showed a child, aged 12 years, with Right Ulnar Paralysis which had developed gradually two months ago without evident cause and which was improving under electricity and massage. He also showed, with Dr. A. J. Hutchison, a man who was suffering from Spasmodic Dysphonia and who had previously had lead colic and wrist-drop. Dr. Hutchison remarked that spasmodic dysphonia was rare and usually occurred in voice-users, such as clergymen. In this case there was anæsthesia of the palate also and he thought the condition a kind of ataxy of the larynx due to lead. Improvement was taking place under treatment for lead poisoning.—Mr. V. T. Greenyer showed a girl, aged 15 years, whom he had treated successfully for Tuberculous Disease of the Knee-joint by injection of iodoform emulsion two years before.—Dr. L. A. Parry read notes of seven cases of Strangulated Hernia which he had seen lately and remarked on the danger of taxis in young children. He also related a case of acute intestinal obstruction in an *infant from strangulation under a band, in* which he had performed resection of the intestine; he showed the post-mortem specimen.—Mr. G. D. Kerr read [illegible] ica which he had treated [illegible] quency currents.—It is [illegible] meeting of the society.

Plaistow and Canning Town Medical Society.—A meeting of this society was held on March 9th, Dr. W. O. Taylor being in the chair. The annual report was read and passed.—The following gentlemen were elected office-bearers for the year: President, Mr. J. J. Harvey; vice-president, Mr. H. A. Nelson; honorary treasurer, Mr. H. S. Beadles; and honorary secretary, Dr. E. Hay.—Mr. Percy Rose exhibited a Liver and a Spleen with markedly thickened capsules resulting from chronic peritonitis consequent upon chronic interstitial nephritis.—Dr. Hay showed an infant with Dermatitis Gangrænosa in the Genito-crural Region. There was no antecedent varicella or any history of a specific fever to account for this form of local gangrene of the skin, but an elder child in the same family was stated to have just recovered from a similar dermatitis which developed shortly after an attack of diphtheria some three months previously.—Dr. J. Biernacki opened a discussion on the Difficulties in the Diagnosis of the Common Fevers.

South-West London Medical Society.—A meeting of this society was held on March 8th at the Lister Institute of Preventive Medicine, Chelsea, Mr. E. F. White, the President, being in the chair, when Dr. Allan Macfadyen gave an address on Some of the Bacteriological Work carried on in the Institute. He passed in review the various micro-organisms affecting the alimentary tract and demonstrated the method by which the Klebs-Löffler bacillus was isolated. He considered that the antiseptic action of the gastric juice was much over-rated and that most organisms were able to survive its action in the stomach and to pass on to the intestine. He divided food poisons into three groups: (1) food poisons already formed before entering *the body; (2) food poisons due to the presence of a group of* organisms called the "Gartner organisms"; and (3) food poisons due to the "paratyphoid bacilli," which were intermediate between the typhoid bacilli and the Gärtner organisms.—At the close of the lecture numerous cultures *and microscopic* specimens were exhibited.

Bristol Medico-Chirurgical Society.—A meeting of this society was held on March 8th, Dr. Reginald Eager being in the chair.—Dr. H. Waldo showed a case of Leukæmia and Dr. E. W. Hey Groves a case of Multiple Congenital Dislocations.—Dr. A. Ogilvy showed the Orbital Exostosis removed from a patient shown at a previous meeting.—Dr. James Swain showed a Large Broad Ligament Fibroid; and Dr. J. Lacy Firth a Fibroma removed from the abdominal wall.—Dr. Waldo read a paper on the Causes and Treatment of Baldness, and Dr. J. O. Symes read a paper on Cytodiagnosis.—A number of the members present discussed the cases, specimens, and papers.

Wigan Medical Society.—A meeting of this society was held on March 9th, Mr. J. Chronnell, the President, being in the chair. After the usual preliminary business was over a paper on Puerperal Fever was read by Dr. T. B. Grimsdale, lecturer in clinical gynæcology at the University of Liverpool and gynæcological surgeon at the Royal Infirmary, Liverpool.—A discussion followed in which Dr. J. Blair, Mr. M. G. McElligott, Mr. Bowen, Mr. E. H. Monks, Dr. R. P. White, Mr. H. Litherland, Dr. J. Jackson, and the President took part.

University of Oxford.—Attention is called by the secretary of the Board of Faculty to the fact that the new regulations as to the production of certificates of instruction on entering names for the examinations for the [illegible] will take effect at the next [illegible] erm, 1905, commencing on [illegible] orms are supplied by the [illegible] ies, Old Clarendon-building. [illegible] the degree days appointed [illegible] 4th; Thursday, May 25th; Thursday, June 22nd; Thursday, June 29th; and Saturday, July 8th.

The Chemists' Exhibition.—The annual exhibition was held this year in the Covent Garden Theatre and was formally opened by Mr. Glyn-Jones on March 13th. The movement commenced ten years ago, still enjoys considerable patronage, and is no doubt of great interest to pharmacists, perfumers, and others. Amongst the visitors were several medical men who take this convenient opportunity of making notes on the advances of pharmacy and of becoming acquainted with new medical and pharmaceutical appliances. The arena of the theatre afforded ample space for the exhibits which were made as attractive as possible. Apart from trade interests there were several exhibits worth seeing from a purely hygienic and scientific point of view.

Reviews and Notices of Books.

The Diseases of Women: a Handbook for Students and Practitioners. By J. BLAND-SUTTON, F.R.C.S. Eng., and ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Edin. Fourth edition, with 127 illustrations. London: Rebman, Limited. 1904. Pp. 520. Price 11*s.* net.

IN the fourth edition of this handbook of Diseases of Women the authors have managed to incorporate much new material without increasing the size of the work. We notice a considerable number of additions and alterations in various chapters. In discussing malformations of the reproductive organs they have adopted the following classification—viz., (1) malformations by arrest of development; (2) malformations by the persistence of septa; (3) malformations by excessive development; and (4) malformations by a combination of the male and female characteristics. In discussing the question of the malignancy of uterine fibroids they point out that the great defect of nearly all such recorded cases is the absence of a complete history. Sarcomata are so prone to give rise to secondary deposits that any case which runs its natural course to a fatal issue might be expected to show secondary nodules in the lungs at any rate. As they point out, the term fibroid includes several kinds of tumours, amongst which there is a soft jelly-like uterine tumour which is met with most commonly in the interval between the twenty-fifth and the thirty-fifth year, associated with profuse metrorrhagia and profound anæmia, and which on section resembles a mass of myxomatous tissue. This tumour is often described as a degenerate fibroid but is in reality a primary condition and serves to bridge the interval between the true fibromyoma and the sarcoma of the uterus. We gather that the authors do not believe in the occurrence of the malignant degeneration of a fibroid tumour of the uterus but rather are inclined to think that in all such instances the growth has been a malignant one from the very commencement. Two very interesting cases of carcinomata of the Fallopian tube are recorded and illustrated in this edition. In the instructions given for the conduct of gynæcological operations the dictum is laid down that "nothing should be allowed inside a patient's abdomen which has not been boiled especially for the operation, and as the surgeon's hands cannot be sterilised by heat he should wear rubber gloves which have been boiled."

The work retains its main characteristics; it is clearly written and although it does not enter into any great detail upon many of the subjects treated, yet it is a good example of its class. The opinions are mainly those of the senior of its two authors and while we may not agree with all that he teaches we are certainly not left in any doubt as to his views upon many debateable points in gynæcology.

About Dreaming, Laughing, and Blushing. By Sir ARTHUR MITCHELL, K.C.B. Edinburgh and London: William Green and Sons. 1905. Pp. 157. Price 5*s.* net.

IN this little book the author has stated opinions which he holds and has endeavoured to support them with fairness. He recognises that they are only opinions but ventures to think that, even if they are not fully accepted, they may still be regarded as worthy of consideration because of their having "a possible useful outcome in the general study of mental disorders." The study of dreams appears to Sir Arthur Mitchell to lead to the following opinions among others:—That there is no such thing as dreamless sleep; that thinking is involuntary—to the extent, at least, that we cannot cease to think under any order of the will; that thinking never ceases during life and is essential to the continuance of life; that dream-thinking is uncontrolled and undirected by the will, is never coherent and concentrated, is more or less of the same character as thinking in delirium, and constitutes a state of mental disorder which is not a state of disease: that thinking when awake is always to some extent under the control of the will by which it is directed to a subject and kept there; that there are many degrees of sleep and wakefulness and as many degrees of efficiency in the controlling power of the will; that thinking, like breathing or the beating of the heart, does not cause a sense of weariness, though all three have a wearing-out effect on all the organs concerned; that the will's inhibiting and directing work brings fatigue and a demand for rest; that the will finds this rest and refreshment in sleep; and that the frequent occurrence of a state of disordered mind in sleep does not do us harm but on the contrary does us good. Some of the conclusions which seem to be the outcome of Sir Arthur Mitchell's study of laughter are as follows:—That laughter is a state of mental disorder which is evidenced by the irrational and purposeless phenomena attending it and the absence during their continuance of all coherent thought; that these short states of mental disorder, which may be very frequent, do not hurt us, but on the contrary do us good; that laughter is not, even usually, the expression of unalloyed pleasure and joy; that on the contrary it very often expresses states of mind which are mean, contemptible, and cruel, the moral faculty being then in abeyance; and that laughter so arising is only pardonable on the view that it is a state of mental disorder. The study of blushing seems to lead to the following conclusions:—That blushing is always the expression of a special mental state; that it causes another mental state which is a state of mental disorder; that blushing is involuntary, is the exclusive property of man, and occurs in all races of men; that it abounds in the young and practically ceases in advanced age; that the inhalation of nitrite of amyl causes the face to flush and that this seems to be attended with the same confusion of mind as that which attends the blush of shame; and that the flush of anger and many other flushes are altogether different from the blush of shame.

LIBRARY TABLE

Atlas and Epitome of General Pathologic Histology. By Docent Dr. HERMANN DÜRCK of the Pathologic Institute, Munich. Authorised translation from the German. Edited by LUDVIG HEKTOEN, M.D., Professor of Pathology in Rush Medical College, Chicago. With 176 coloured illustrations and 36 figures in black and colours. London, Philadelphia, and New York: W. B. Saunders and Co. 1904. Pp. 371. Price 21*s.* net.—The atlas before us contains a large number of admirably drawn reproductions of microscopical preparations illustrating conditions met with in morbid histology. They are beautifully reproduced and afford a striking example of the lithographer's art. The text contains a condensed summary of the principal facts of pathology; the statements contained in it appear to be correct and brought up to date. Having thus paid a well-merited tribute to the author—we may add the translator—to the artists, and to the publishers whose enterprise is so strikingly exemplified in the production of such a book at the price named above, we may confess to a feeling of doubt as to the exact place which such a work is expected to occupy in medical education. We can imagine a good and a bad use to which it may be put. It may rightly be used by the teacher of morbid histology to illustrate to his class conditions of which he does not happen to possess specimens at hand. It may wrongly lead students to rely upon its aid as a means of "cramming up" a certain number of pathological appearances with a view to "spotting specimens" in examinations, to the neglect of the study of actual preparations. In this latter case we think that disaster will result, since in an atlas of this kind it is impossible to preserve any strict perspective in the choice of illustrations, and rare and curious conditions appear on an equal footing with common and important morbid states. This peculiarity is at once evident from the fact that just one-third of the whole book and practically half the number of plates contained in it are devoted to the illustration of different varieties of tumours, a quantity quite out of proportion to their importance from a student's point of view. Indeed, here the very minuteness of the classification will lead to confusion in the mind of one not already well versed in the subject. Hence, while we advise those who have the opportunity of looking into this atlas to avail themselves of it, we cannot think that students with but a limited amount to spend on books will find it worth while to purchase the volume.

The Splendor of the Human Body. By the Right Rev. C. H. BRENT, D.D., Bishop of the Philippine Islands. London, New York, and Bombay: Longmans, Green, and Co. 1904. Pp. 60. Price 2*s.* 6*d.* net.—This is a thoughtful and scholarly address upon the body considered not merely from the physical point of view but as "the living dress" of the soul. Bishop Brent urges in plain and simple language that the body is the crown of creation in this world and that it is indissolubly linked with the rest of creation. From this it follows that the body should be used with due care; that it should neither be made the toy of the passions on the one hand nor considered as the enemy of the soul on the other. This last, of course, was the error into which the Ascetics fell. Beginning with asceticism (*ἀσκησις*) in its original meaning—i.e., discipline or training—they gradually came to regard the body as an evil; then came the inevitable rebound and excess in the other direction. Bishop Brent ends with an exhortation to self-restraint and we consider his little book to be one which all parents may study with advantage and may give to their children.

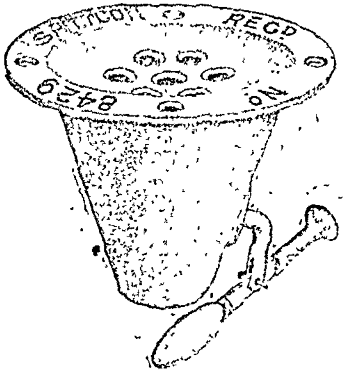
Obstetric and Gynecologic Nursing. By EDWARD P. DAVIS, A.M., M.D., Professor of Obstetrics in the Jefferson Medical College and Philadelphia Polyclinic; Obstetrician and Gynecologist to the Philadelphia Hospital. Second edition; revised. With numerous illustrations. London, Philadelphia, and New York: W. B. Saunders and Co. 1904. 12mo, pp. 402. Price 8*s.* net.—In issuing the second edition of this useful book the author has taken the opportunity of thoroughly revising it and adding a certain amount of new matter. No very marked alteration has been made in the character or the scope of the work. It has evidently met with a fair amount of success and, as we pointed out in our review of the first edition, it forms a useful and practical text-book for nurses. There are many points of considerable practical value contained within its pages and Professor Davis has been successful in limiting his information to such an amount as may fairly be comprehended by any intelligent nurse.

The Plenum or Propulsion System of Heating and Ventilation. By HAROLD GRIFFITHS, A.R.I.B.A., F.S.I., M.S.I. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1905. Pp. 107. Price 4*s.* 6*d.*—With regard to ventilation there exist now broadly two schools—one which favours ventilation by so-called natural means and the other which maintains that mechanical ventilation either by propulsion or extraction is alone satisfactory. However this may be, practical experience would appear to be deciding in favour of the propulsion as opposed to the extraction system of mechanical methods. There can be no doubt that the plenum or propulsion system of heating and ventilation is making progress and the installations which have been fixed in this country have so far given very satisfactory results. There are certain minor points connected with its supervision, however, which if neglected may raise a prejudice. Mr. Griffiths indicates these apparent defects. As he shows, they only exist so long as carelessness in working the system occurs. Complaint is often made, for example, as the author points out, that the plenum system gives rise to "bad air." When such a complaint is justified it is often due to a neglect to keep the apparatus clean. Filth, for example, accumulates in the nuts on the batteries and elsewhere and instead of being washed away on the first opportunity is allowed to remain until it is carried with the air into the rooms. As another example may be quoted the omission for three months of a man in charge of the installation to keep the filtering and humidifying screens supplied with water. Of course, such inexcusable negligence will easily account for unsatisfactory results. We have had occasion to visit public buildings in which the plenum system has been installed and have invariably found the process to be working satisfactorily and to the health, comfort, and convenience of the occupants of the various rooms and offices. But, as the author is careful to point out, "superior supervision and occasional surprise visits at irregular intervals are essential to insure the proper and efficient working of a plenum installation." It is often the case that any prejudice that may be entertained against the system is overcome when the efficiency of the installation is maintained. The author evidently has practical experience on the subject and deals with all the technical points concerned in a clear and intelligible manner. While acknowledging that defects may arise he is strongly in favour of the system. The book is a useful guide on the subject.

New Inventions.

A SELF-EMPTYING SPITTOON FOR RAILWAY CARRIAGES.

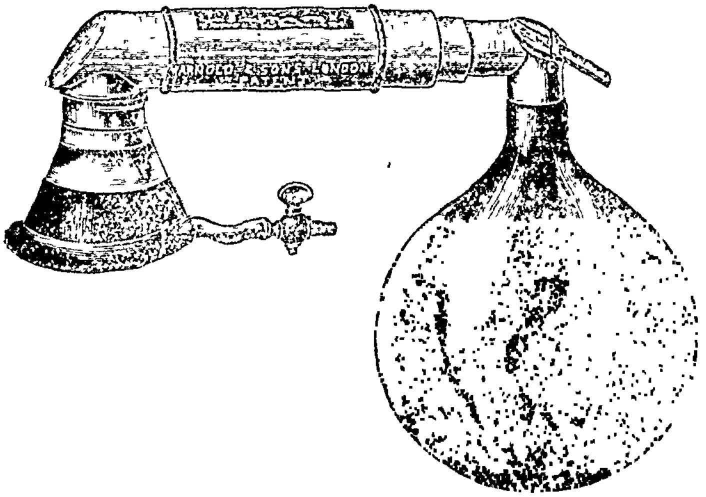
SPITTOONS of the pattern shown in the illustration are fixed in the floor of a railway carriage so that their upper surface is flush with the general level of the floor. The pan or container is of a conical shape and open at the bottom but in order to prevent any upward current of air while the train is in motion there is a hinged flap which closes the aperture. When the pan is partly filled with saliva or other expectorated matter the weight of the contents causes the flap to open so that the liquid is emptied on to the permanent way and the bottom is again closed automatically. For the



convenience of smokers and others several spittoons are placed in the floor of each carriage where they are used, and dripping umbrellas may also be held with their tips in the perforated bowl. The dimensions of the spittoons are five and three-eighths inches in diameter and four and a quarter inches in depth; they are made of malleable cast iron and weigh one and a half pounds. They have been in use for some months on the Tynemouth branch of the North-Eastern Railway. Railway passengers who spit freely are not usually refined in their manners but when they get into the habit of using the spittoons the result will be a great improvement in the cleanliness of the carriage floors and less danger from the dissemination of tuberculous sputum which after drying has become converted into dust. Further information relative to the spittoon may be obtained from Mr. George Graham, Westminster Chambers, 43, Victoria-street, London, S.W.

A NASAL INHALER FOR THE ADMINISTRATION OF ETHER.

With the inhaler represented in the illustration prolonged anæsthesia may be obtained by means of ether administered through the nasal passages during operations in or about the mouth and particularly in extensive dental extractions. It consists of a nose-piece, A, which rotates through half a circle and is fitted with an indiarubber pneumatic cushion connected with a tubular chamber B in which lies a loosely fitting sponge, the other end of the chamber being fitted with the angle-joint C and the indiarubber bag D of a Clover's inhaler. In the chamber B there is a large aperture which serves the purpose of charging the sponge with ether and which can be closed by a sliding sleeve. There is a small hole closed by a sliding cover C at the angle-joint of the bag; through this a charge of ethyl chloride can be squirted into the bag for the purpose of inducing anæsthesia before the ether is added if so desired. For a short operation such as the extraction of all the teeth the uncharged inhaler is placed over the nose, the bag hanging over the patient's head, the patient being instructed to keep the mouth closed and to breathe only through the nose. About two cubic centimetres of ethyl chloride are then squirted into the bag through the small aperture C which is immediately closed. As the patient becomes anæsthetised the large aperture B is opened, about two drachms of ether are poured on the sponge, the opening is again closed, and the patient passes into deep ether anæsthesia without any struggling or choking. The mouth is immediately opened and the operation proceeded with, the inhaler being kept in position until the operation is over and the operator working as deliberately as he desires. Patients as a rule recover very quickly (in a few minutes) and without sickness. For longer operations such as that for ununited fracture of the jaw, it is perhaps wiser to induce a full deep anæsthesia with an ordinary inhaler and when the operation is about to commence to maintain anæsthesia with the nasal inhaler, charging it however with about an ounce of ether in the indiarubber bag as the sponge chamber will not hold sufficient ether for prolonged administration. During an operation for ununited fracture of the lower jaw in a powerful man addicted to alcohol perfect anæsthesia was in this way maintained without any trouble for over half an hour, the surgeon being in no way impeded or interrupted in his work. During the past nine months the inhaler has been tried in many dental and various surgical cases with surprising and unvarying success. The whole apparatus may be sterilised by boiling. The makers are Messrs. Arnold and Sons, West Smithfield, London, E.C.



H. C. Drury, M.D. Dub.
Dublin. M. F. Thomson, L.D.S. Edin.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on March 9th, Mr. John Tweedy, the President, being in the chair.

Mr. W. H. A. Jacobson and Mr. Bilton Pollard were introduced and having made declarations in the terms of the oath prescribed by the Charter of 1800 were admitted members of the Court of Examiners.

A report was read from the Board of Examiners in Dental Surgery recommending the adoption by the Council of synopses indicating the range and extent in the subjects of anatomy, physiology, surgical pathology, and surgery for candidates for the licence in dental surgery.

The Senior Vice-President reported the delivery of the Hunterian Oration by the President on Feb. 14th.—The best thanks of the Council were given to the President for his oration and he was requested to publish it.

The President reported the delivery of the Erasmus Wilson lectures by Mr. Leonard S. Dudgeon and Mr. Percy W. G. Sargent on *Peritonitis* and he also reported that Mr. Stephen Mayou had delivered a course of three lectures on the Changes Produced by Inflammation in the Conjunctiva.

The President reported that in pursuance of the provisions of the Bradshaw bequest he had chosen Mr. Henry T. Butlin as Bradshaw lecturer for the ensuing collegiate year.

The Chairman of the Library Committee reported that the President had presented to the College eight volumes of fifteenth century books, forming a valuable and interesting addition to the collection of books of that period in the library.—The best thanks of the Council were given to the President for his gift.

The President reported that Sir Gilbert Blane's medals had been awarded to Surgeon Sidney Thomas Reid, H.M.S. *Vestal*, 1901-02, and Surgeon Robert William Glennan Stewart, H.M.S. *Latona* and *Thames*, 1903.

In accordance with the report of the Museum and General Purposes Committees it was resolved not to instal the electric light in the museum at present; this decision was arrived at chiefly on account of the cost.

Dr. J. Ward Cousins presented a report of the proceedings of the Central Midwives Board for the past year. The report contained many matters of great interest and among these may be specially mentioned the necessity which exists for an amendment to the Midwives Act providing for a fair scale of remuneration of the medical men who may be summoned in cases of difficulty and danger by midwives.—The best thanks of the Council were given to Dr. Ward Cousins for his report.

A letter was read from the Lord President of the Privy Council transmitting a copy of a communication received from the Russian Chargé d'Affaires in regard to the Fifth International Congress on Gynæcology to be held at St. Petersburg in September, 1905.

After discussion it was resolved that the clause in the regulations of the Council relating to meetings of Fellows should be further suspended and that in place of the meeting of Fellows a subscription dinner should be held at the College on the day of the Council election in July next.

The President reported that he had had the honour of dining with His Majesty the King at Buckingham Palace on March 4th.

THE LANCET.

LONDON: SATURDAY, MARCH 18, 1905.

Hospitals in their Relation to the Public and the Profession.

THE conference on Hospital Reform recently held under the auspices of the British Medical Association is one of many indications of the important movement now in progress for the organisation of the medical relief of the sick poor. If the actual conclusions arrived at by the conference seem only to touch the fringe of a great subject the facts that unanimity was secured on some points and keen interest was manifested in many more should give satisfaction to the responsible organisers of the meeting. Satisfaction may also be felt that it was found possible to bring together from all parts of the country many of the proverbially busiest of laymen who have most time and are willing to devote a considerable proportion of it to hospital administration. The meeting together in such large numbers of busy laymen and busy medical practitioners to discuss hospital matters is worthy of note, not only because of its possible results but because of its probable cause. No mere desire to exchange views on methods of heating and ventilation, or even on a suitable age-limit for the retirement of the medical staff, would have brought together in London representatives of hospitals in Scotland and Wales as well as in the most distant parts of England. If medical practitioners were instrumental in seeking this conference because their profession is feeling the intolerable strain of providing without payment the constantly increasing demands for hospital treatment the laymen were no doubt anxious to discover some means of relief from the equally intolerable strain of collecting money to meet the same demands. So long as the limits of medical charity can be kept within reasonable bounds the governors and the staffs of our hospitals find mutual satisfaction in administering to the relief of suffering. They are at the present time being drawn still more closely together in an attempt to deal with developments which appear almost overwhelming. The exact direction of their united efforts must be a matter for anxious and careful consideration, for success in one direction may mean disaster in another. The multi-millionaire who would free our hospitals from debt and allow for such extensions as would meet all present claims for free medical relief might, while delighting the hearts of the governors, run a considerable risk of straining the charity of the profession to the breaking point. For it must be clearly remembered in dealing with this question that whatever success attends the labour of the governors of hospitals in securing funds for increasing their charity necessarily involves a proportionate increase in the unpaid labour of the medical profession.

It is impossible here to refer in detail to the motions submitted to the conference. Most of them were accepted with but slight modification. One of considerable importance was, however, negatived. To this we wish to draw particular attention on account of the divergent views which were expressed during its discussion. The motion was worded as follows: "That no charge for the treatment of any patient shall be made." To most professional readers it will be obvious that the object of the committee in insisting on the absence of payment is to impress upon patients that the hospital is a charity, relying upon their sense of honour not to avail themselves of it unless justified by their circumstances. While compelled by experience to doubt whether the sense of honour in these conditions is an effective deterrent of abuse, this point of view seems to be clear and it was apparently so regarded by the committee, for no great pains were taken to explain the motive underlying the proposal. No wonder, perhaps, that this motion was negatived when some of the laymen regarded the imposition of a small charge for medicine as a useful means of preventing that overcrowding of the out-patient department to which general practitioners are supposed to object. Perhaps, too, the "sense of honour" argument would in any case have been a little discounted by a subsequent proposal to institute inquiries into the financial fitness of every applicant for hospital relief. It is difficult to rely on the effect of trusting to a man's sense of honour when at the same time you are taking active steps to secure the same end by other means. For our part we think that due inquiries into an applicant's financial fitness are more likely to secure that charity shall be properly dispensed than is the most elaborate attempt to bring home to the applicant the dishonour of accepting unneeded charity.

While regarding with great satisfaction any attempt to inform the public, and especially the lay administrators of hospitals, as to the view of the profession with respect to medical relief, we cannot help regretting that the conference was not made use of to arrive at a common understanding of some general principles. The relations of hospitals to the medical work of the Poor-law and the proper attitude of hospital committees to paying wards were subjects distinctly ruled out of the purview of the conference, though they doubtless influenced both the discussion and the voting on some of the motions. At the end of the conference representative laymen were nominated to consider further the resolutions with the committee of the British Medical Association preparatory to making some authoritative statement to the public. It is greatly to be hoped that this joint committee will take a wide view of its reference and will look a little more deeply into the origin of our present troubles with the object of securing a more drastic and permanently effective treatment. No scheme of hospital reform can be said to go to the root of the matter which does not accept as a fundamental proposition that an attempt should be made to prevent the overlapping of hospitals, on the one side, with the Poor-law and, on the other side, with provident dispensaries. Absolutely necessary reforms are prevented in the Poor-law and in the provident system of medical relief by the competition of voluntary hospitals. The State is encouraged to neglect its obvious duty to sick paupers by the knowledge that the charitable public can persuade the medical profession to do for nothing work which should be undertaken by a properly paid Poor-law medical service. General practitioners are handicapped in their attempts to develop the provident system amongst the working classes by the constantly increasing competition of the free out-patient departments of hospitals. From want of proper organisation the hospitals are actually preventing developments which if encouraged would relieve them of a great burden of work. And this work which the hospitals unnecessarily take from the Poor-law and from the private practitioner could be better done by these agencies. The Poor-law can afford, must afford, to keep a pauper until he is once more an effective worker, whilst the general practitioner can follow a provident patient to his home whenever the nature of his illness demands it. Any attempt to prevent this overlapping of different forms of medical relief must be preceded by an attempt to define the proper sphere of hospital work. It is said that it baffled the most fluent French scholars amongst us to explain to our Parisian colleagues during their recent visit to London the essential difference between a Poor-law infirmary and a voluntary hospital. In view of the growing tendency of municipalisation it is no mere academic duty to establish the *raison d'être* of the crowning glory of the metropolis. In the interest of medical education no less than the advancement of medical science it is much to be desired that the great hospitals with medical schools attached should be placed upon a basis of absolutely unassailable public utility. Their proper position is not in competition with Poor-law infirmaries and with charitable organisations through which the general practitioner deals with ordinary cases of illness, but as consultative institutions accessory to these other agencies, where special resources required in selected cases shall be available for every class of patient, whether pauper or private, who cannot afford to pay adequate fees to secure such special resources elsewhere.

In endeavouring to define the proper functions of hospitals and their relation to other medical agencies it is to be hoped that the profession may get clearer ideas of its own proper relation to medical charity. A great deal of the difficulty of controlling medical charity would not exist had it not become an established principle that the charitable public who support hospitals can always obtain medical treatment for the inmates without payment. Whether it would be better for the public and the profession to depart from this principle we will not now discuss. It is enough that it exists and that its existence complicates all questions of hospital reform. It is responsible no doubt for a very natural desire on the part of the profession that hospital treatment should not be indefinitely increased. Although every medical man who accepts a hospital appointment thoroughly recognises the fact that he will not be remunerated for the work which he is called upon to do he does not perhaps sufficiently consider his position from the broad aspect of its economic effect upon the profession at large. Every dock labourer understands the result upon the labour market of his individual act in accepting less than the standard wage and many a one will starve out of loyalty to his class rather than commit this crime against his brethren. The practice of medicine is raised above all commercial considerations by the fact that persons who are sick excite professional as well as public commiseration. But if we urge upon the governors of hospitals that it is not such true charity to throw medical relief broadcast to all comers as to inculcate habits of thrift by encouraging patients to become subscribers to provident institutions, should not medical practitioners remember that their duty to their profession may make it necessary sometimes to forego the satisfaction of placing their services without remuneration at the disposal of any charitable institution that asks for them? These considerations involve large questions of professional policy to which medical men have in the past paid too little attention. It is by their proper study and solution that every class of the community can secure the services of a strong, independent, and generous profession. For the development of our great voluntary hospital system on right lines careful coördination with other agencies having similar aims must be secured, the charitable public must learn to exercise its charity with the wise discretion which regards the interests of the medical man as well as of the sick patient, whilst members of the profession must recognise their obligations not only to themselves and to each other but to the medical profession as a whole and to its various branches.

◆

Specialism.

The question of the proper uses and limitations of what is commonly called specialism is one which is intimately bound up alike with the progress of medical science and with the improvement of medical practice and one which therefore deserves the earnest consideration of the profession. It is obvious, on the one hand, that specialism may be conducive to real advancement in certain directions; and it is at least equally obvious that the great majority of mankind must always be dependent upon the ministrations of physicians and surgeons who regard the whole of the human body as falling within the sphere of their contemplation. If specialism were even now as pronounced as certain sections of the public desire to make it, it would be almost necessary to establish a class of practitioners whose specialism it should be to advise patients as to the specialist whom they should consult and thus to save them from the calamities which might be incidental to seeking the advice of a "liver" man when the stomach was the organ primarily at fault or the advice of a "skin" man when cutaneous troubles were merely consequences of neuritis. The good to be accomplished by specialism is always liable to be counterbalanced by the evils which may arise from comparative neglect of the "special" branch by the general practitioner, who may thus fail to be properly prepared for duties which he may reasonably be expected to discharge. He is in danger of feeling when a few men have possessed themselves, so to speak, of some particular branch of the art of healing that their studies in that direction have been carried beyond his depth and that it is useless for him to attempt to follow them. Even in the three specialisms which have long been regarded as legitimate—ophthalmology, otology, and dentistry—and which have a broad foundation in forms of knowledge or in methods of treatment which are not required in other departments, ill consequences of this description are unfortunately not unknown. Hundreds of cases of glaucoma have been suffered to pass into incurable blindness; hundreds of cases of defective hearing in childhood have been suffered to go from bad to worse, and hundreds of cases of gastric sepsis arising from dental caries have defied all medical treatment simply because the practitioners originally consulted have never thought it their duty to be acquainted with the respective specialisms concerned. To this picture, it need hardly be said, there has been a reverse and specialists consulted for manifest defects of the organs which they were supposed to have appropriated have been known to overlook the fact that these defects were merely symptomatic of grave changes in other portions of the body. The advantages of specialism, whatever they may be, are sensibly diminished when those who follow it are tempted to neglect general medicine and surgery and when physicians and surgeons are tempted to regard the so called special branches of the profession as matters of which they may contentedly remain in comparative ignorance.

Considerations of this kind are becoming more important now than they have been at any earlier period in the history of the healing art, by reason of the vast extension which has recently been given to the applications of physical science to medicine and of the ever increasing amount and complexity of the knowledge which practitioners are called upon to possess. In the middle of the last century a natural philosopher was regarded as a person from whom a fair acquaintance with "science" as a whole might reasonably be anticipated and even at a still later date the President of the British Association for the Advancement of Science was expected to review the progress of the year in almost every department of inquiry. To-day it is commonly admitted that he has enough to do in reviewing the progress in which he himself has been more immediately concerned, and the consequent division of labour has undoubtedly been contributory to a more rapid general advancement. In medicine the conditions have been to some extent the same but the results do not promise to be equally advantageous. The fact that the science as a whole is passing beyond the grasp of individual acquirements, in whatever degree it may be true, must to some extent be a source of danger rather than of advantage to the public, and with possible exceptions in favour of the specialisms which are based upon some extraneous branch of knowledge, as ophthalmology upon optics or otology upon acoustics, the benefit to be derived from specialism in the future is likely to be proportionate to the degree in which its researches are made to enrich medicine in its entirety and to be contributory to the increased efficiency of the general practitioner. In order to secure the attainment of this end its developments and its claims will alike require to be watched with considerable care and to be encouraged or recognised almost in proportion to the degree in which they are calculated to promote the attainment of the end proposed. The professors of subordinate branches of science have always displayed some tendency to lose themselves in over refinements, in verbal distinctions, and in obscure nomenclature, and they have seldom been free from a proneness to exaggerate the value and the importance of the studies to which their own lives have been devoted. In so far as these characteristics attach themselves to so called special branches of medicine or of surgery it should be the business of the profession as a whole to endeavour to arrive at a just estimate of their actual importance and to treat and to recognise them accordingly.

The foregoing observations have to some extent been suggested by the position which certain practitioners have recently assumed in relation to the *diseases of children*. Children under 15 years of age form rather more than a third of the populations of civilised countries and they are not only the immediate causes of far more than a third of the demands which are made every day upon medical practitioners but the whole of their future lives, and even the lives of their offspring and of future generations, may depend upon the way in which the demands thus arising are met. No division of medical science can be more important than that which deals with the differences, in relation to disease and treatment, which exist between children and adults; nor, on the other hand, can there be any which it is more important for the profession as a whole to master. We publish this week a paper by Dr. FRANCIS WARNER which indicates with how much promise the principles of physiology may be applied for the elucidation of the natural development of the functions of the nervous system and *a fortiori* for the prevention or cure of their derangements; and we have before us two reprints from the numbers of *American Medicine* for November and January last respectively on the History of Pediatrics and its Relation to other Sciences and Arts and on the Foundations and Aims of Modern Pediatrics, which may perhaps serve to illustrate some of the dangers of over specialising. Our American friends have seen fit to adopt styles of language and of orthography which seem to us to indicate a very defective appreciation of the value as a national possession of the language of MILTON and of ADDISON, and we are not prepared to condone the neglect of etymology which is displayed in 'fetal', while against "pediatrics" or "pediatrist" we must enter the most energetic protest of which we are capable. If we must have either word at all, especially the latter, it should surely be "pædiatrist," should show that it is derived from *παῖς* and not from *pes*, and that it is intended to mean a child's physician or surgeon and not, as it appears to do, a corn cutter or a bunion curer. But these objections seem comparatively trivial when compared with the manifest tendency of the writers of the articles referred to, one of which is by an American and the other by a Viennese physician and both of which were read at the great exhibition of last year at St. Louis, to separate the consideration of the diseases of children from the domain of general practice and to regard it as a "special" branch of study. In this country, at least, the general practitioner must emphatically be a child's medical attendant and must be prepared to place the most useful means of diagnosis and the most approved methods of treatment at the disposal of those who both numerically and in relation to the character and the significance of their ailments, are usually the most important section of his patients. We shall receive with nothing but gratitude any veritable contribution to a better understanding of children's diseases from whatever quarter it may come, but we are not prepared to welcome either an envelopment of old knowledge in new and somewhat illiterate jargon or a consecration to specialists of researches which should be rendered available for the service of mankind.

The Case of Miller v. Miller and Fowler.

THE President of the Divorce Court in dismissing Dr. CHARLES OWEN FOWLER, with costs, from the divorce suit of MILLER v. MILLER and FOWLER, said that he was about to use a common form of expression, but that he thought it was due to Dr. FOWLER to record that he left the court without a stain upon his character. Dr. FOWLER has, indeed, passed unscathed through one of the severest ordeals to which it is possible for a man to be submitted. The story has appeared at some length in many papers, but it contains lessons for medical men that may make its repetition useful. The petitioner sought to divorce his wife and in addition to evidence which might be regarded as formidable proceeding from himself, from servants, and from others, the wife went into the witness-box and swore that she had committed adultery with Dr. FOWLER, the medical man who for some time had constantly attended herself and her children. Dr. FOWLER had but one protection against the combination of flat perjury, gross exaggeration, prurient suggestion, and stupid error which for a time threatened to destroy his professional career and to ruin his life. He had carried on the profession of a medical man honourably and in the business-like manner which is a necessary element of success in the conduct of a general practice of any dimensions. It was the business-like methods of his life that served as his safeguard. The self-accusing wife and others proved that many letters or notes had passed from her to her medical man, followed by visits on his part to her at her house. The medical man's professional records showed that these visits were of a strictly professional nature, while his wife (who never wavered in her confidence in her husband), his partner, and his dispenser showed conclusively that the written communications were only requests for Dr. FOWLER'S attendance. They were as free to open these notes as Dr. FOWLER himself, and his partner responded to them when the member of the firm to whom they were addressed was unable to do so. Dr. FOWLER, in his own evidence, admitted frankly that he had been in the MILLERS' house perhaps half a dozen times in a non-professional capacity and he took an obviously honest course in dealing with the statements of Mrs. MILLER as to his relations with her. He suggested no delusions, hysterical or otherwise, on her part. He refused to speculate as to the psychological causes which might have induced her to enter the witness box in order to declare herself an adulteress and him her paramour. He denied the truth of her story absolutely and entirely, and if it could only follow that it was due to "pure wickedness" on her part, as her counsel put it to him, he was content to leave the [illegible] his [illegible] To alleged details of his conduct, which if [illegible] corroborated her tale, he was able to gi[illegible]ly unequivocal answer. He was invited to [illegible] was merely a coincidence that the petitioner returning earlier than usual upon a particular occasion had found him in the house, but his answer was a direct denial that any such incident had ever taken place. And even his carefully kept register of professional services rendered and the testimony of colleagues, friends, and wife were almost insignificant in effect compared with the fearless manner in which Dr. FOWLER gave his evidence, without suppression or exaggeration. It is such evidence as this that no cross-examination can seriously affect.

We have used the word business-like in reference to the manner in which Dr. FOWLER'S practice was carried on, and we would call attention to the important bearing which this had, not because his written records would be evidence in his favour—for this they were not—but because they enabled him, and those with him, to refresh their memories as to incidents which might otherwise have been forgotten. Owing to the orderly manner in which Dr. FOWLER'S diary was kept he and his witnesses were able to speak with confidence and accuracy as to the date, hour, and cause of every attendance that he rendered. Accusations by women against men are easy to make but hard to refute. In the case of medical men they are for obvious reasons infinitely easier to make than where members of other professions are concerned and to dispel them is even more difficult. The evil-minded are ever ready to believe that what seem to them opportunities for misconduct are not unlikely to be taken advantage of. The danger to the medical man is always present so long as he follows his calling; no prudence on his part can enable him to escape it altogether. He can only do his best to avoid everything that can give the smallest cause for calumny, and endeavour to secure esteem by the unostentatious and industrious performance of his professional duty and by living at all times the life of an honourable citizen. Then, if he should have the terrible misfortune to find himself in the position of Dr. FOWLER, he will be able to face the trial with manly confidence in the experience and in the upright impartiality of his country's judges, as well as with faith in the desire of a British jury to do justice between man and man. We heartily congratulate Dr. FOWLER upon the complete exoneration which he has been able to obtain from the foul charges brought against him.

Annotations.

"Ne quid nimis."

THE DISPOSAL OF THE SLAIN IN BATTLE.

THE appalling carnage in the Far East raises the very serious question as to what will be done as regards the disposal of the many thousands slain. Some thousands of tons of human flesh must be lying strewn round the ancient capital of Mukden and it would seem almost incredible that natural agencies could be trusted to remove this enormous pile of dead and to render it inoffensive, not to say harmless, to the living. Fortunately intense cold prevails which will stay the putrefactive process for a time, but sooner or later the opposite extreme of temperature must come and then this awful waste of human life will become a disgusting menace to health. Presumably there is an unlimited area in which the corpses may be interred but it will be a vast cemetery and the task of burying will take a long time to complete. Still, it is well known that the soil possesses a very remarkable power of disintegrating and purifying animal material through its countless microscopic agencies; these, however, it may be noted, are only found to operate at a very small depth. The cremation of thousands of tons of human flesh would be a gruesome and ghastly undertaking and we imagine that it would be hardly possible on such a dreadful scale. The Japanese, who are so well advanced not only in methods of warfare but in medical science also, will no doubt apply their common sense and wonderful intelligence to this unpleasant problem in a manner worthy of their best traditions.

DO BUILDING BY-LAWS IN RURAL DISTRICTS INHIBIT BUILDING OPERATIONS?

IN a leading article in THE LANCET of Feb. 11th we referred to the circumstance that there were no building by-laws in force in something like 40 per cent. of the rural districts in England and Wales and we used this fact as tending to controvert the contention of those who urge that the enforcement of such by-laws is largely responsible for the rural depopulation which all those interested in the physical well-being of the people deplore. As we stated, it had never to our knowledge been shown that in rural districts without building by-laws the population was increasing whereas in districts with by-laws it was decreasing. The problem of depopulation was, we urged, a highly complex one and the influence of by-laws upon it was not great. It is interesting, therefore, to turn to the last annual report of Dr. R. W. C. Pierce, the medical officer of health of the Guildford rural district, which shows in tabular form the number of new houses built during the last four years in the four parishes with by-laws as compared with the number built in the 14 parishes without such by-laws. The combined area of the first group of parishes is 15,609 acres and the population is 8419, whereas the corresponding figures for the latter (non-by-law) group are 39,716 acres and 12,507 people. During 1901–04 there were 159 houses built in the *four* parishes with by-laws as against 172 in the *fourteen* parishes without by-laws. These figures are instructive as also are some observations made by Dr. Pierce with respect to the erection of wooden cottages. It is a common contention that if the erection of wooden houses were permitted such structures would spring up like fungi all over the country. The experience of the Guildford rural district is as follows: "In all but four of the [18] parishes of the district ...... builders are at liberty to put up cottages of wood or other material than bricks as they please, but no one has yet done so." As Dr. Pierce adds, "the chief objection to wooden structures would be their short life. This could possibly be overcome by sanctioning their occupation for a definite period." Finally, Dr. Pierce shows by another table the number and the situation of new houses for which water certificates were granted during 1904 and such list, as he remarks, suggests that "the proximity of water mains has more to do with the encouragement of building than the absence of by-laws." There is one point in Dr. Pierce's interesting report upon which we cannot quite follow him. He remarks that "the difference in the cost of erection of an average brick cottage in the parishes with and without by-laws probably does not amount to more than a difference of 6*d.* a week in the rent at the most." We doubt, however, whether the capital expenditure necessary to carry out the health provisions of the new rural by-laws of the Local Government Board would be such as to necessitate an interest of 26*s.* per annum; indeed, it is difficult to understand how any modern builder could in these days be persuaded as a commercial undertaking to build a house without some regard to the essentials of health, and the difference between his maximum and the very small requirements of the new model series of by-laws would not, we think, be so great as the estimate given by Dr. Pierce. We are very glad to see that the suggestion which we made in our leading article to the effect that another deputation, consisting this time of those who see the necessity for reasonable building by-laws, should wait upon the President of the Local Government Board has since been acted upon. On Feb. 23rd Mr. Long received a deputation consisting of representatives of rural district councils, trade councils, working men's societies, and democratic federations, and his reply was an admirable exposition of statesmanship. In effect he gave the deputation to understand that he would hear both sides and would act as he thought best in the interests of the public health. Obviously, unnecessary restrictions upon building in rural districts should not be imposed and we are quite in favour of any modifications which will not detract from the essentials of health. We think, however, that a somewhat distorted aspect has been given to the controversy in the lay press and that it is important for the real facts to be made known. One of these facts is that wooden cottages can be erected under the new rural by-laws and the other is that the difference in cost between a cottage erected under those by-laws and a *habitable* cottage erected without such by-laws is very small.

CONDIMENTS.

WHILE it cannot be said that the use of condiments in the daily dietary has found a complete chemical or physiological explanation yet it is, of course, broadly known that in many cases they are essential constituents, for they improve the flavour of more or less tasteless foods and, indeed, promote digestion by exciting the flow of the various digestive secretions. Flavour is undoubtedly a great promoter of digestive success. It is not quite clear, however, why, for example, a person takes mustard with ham, pork, or beef and not with mutton; vinegar with salad or lobster and not with ham or other foods. In generalising, however, it would appear that condiments are chosen to accompany those foods which are less digestible or which are richer than others. Mutton, for example, is more digestible than beef, pork, or duck and it is to these three that mustard is generally added. Vinegar, again, is known to soften the hard fibre of both meat and vegetables; hence it probably renders such foods as crab, lobster, salmon, salads, red cabbage, and walnuts less tough and more digestible. Vinegar in dressing and sauces probably has a similar action. As a rule the increased amount of soluble or extractive matters in a food is in direct relation to its digestibility and nourishing value, not that the extractive principles are in themselves nourishing but because they are appetising and promote the flow of digestive juices. To the man with robust appetite the presence of tasty extractives or the use of condiments is probably superfluous. Bread and cheese and beer form a most enjoyable meal after brisk exercise in the open country air but during sedentary occupation very little relish is experienced for such a simple repast. Hunger is the best sauce but failing hunger the appetite must be coaxed and herein lies the true uses of sauces, condiments, and other aids. The abuse of condiments has its attendant evils. The excessive use of vinegar is calculated to lead to an anæmic condition, while it has an unfavourable influence on gout. Some silly women take vinegar to produce a pale complexion. Similarly, a free indulgence in pepper or mustard, which are both *irritants*, is likely to have an irritating effect upon the organs of secretion. On the other hand, their moderate indulgence promotes digestion for they act as carminatives.

Highly savoury dishes are incompatible with good digestion and the prevailing preference for liberally garnished "messes" instead of plain, simple food is to be deplored. The habit of partaking of highly seasoned food accounts very largely for the decline in the consumption of light elegant wines of the claret type. The bouquet and flavour of a delicate wine are completely spoiled by rich-tasting sauces or spices. Salt is perhaps the commonest condiment of all and yet man practically stands alone amongst animals as a regular consumer of it in the more or less pure state and as a definite adjunct to his food. Salt is present in most foods but the amount in the majority of cases would not appear to satisfy man's needs or he would not instinctively add more. Moreover, salt may not necessarily exist in the free state in foods of natural origin but may be loosely combined with organic constituents. There can be little doubt that salt plays a greater part than that of a mere condiment in the body, for it possesses solvent powers which, besides "drawing out" the flavour of food, facilitate the absorption more particularly of proteid and thus increase tissue metabolism. The pleasures of feeding would be very decidedly diminished if salt and condiments were banished from our tables. It is noteworthy, moreover, that amongst condiments most of them, whilst favouring the digestive processes, are antiseptic, so that their action tends to counteract any disposition to undesirable fermentation.

CONGESTION OF THE BRAIN IN A CASE OF GENERAL PARALYSIS FORCING THE CEREBELLUM INTO THE FORAMEN MAGNUM.

AT the meeting of the Société Médicale des Hôpitaux de Paris on Dec. 23rd, 1904, M. Faure-Beaulieu reported a case of general paralysis in which a remarkable condition was found post mortem—great congestion of the brain forcing the cerebellum into the foramen magnum of the occipital bone. A man, aged 35 years, was admitted into hospital on Oct. 18th, 1904. He denied having had any venereal disease but he showed signs of old iritis. In 1900 he contracted malarial fever on the Congo. In May, 1904, after a severe financial loss, he took to drink. Instead of being as formerly, calm and well balanced, he rapidly became emotional, irascible, and subject to violent attacks of anger. Soon his power of walking became defective and his legs bent under him. Then his upper limbs became weak. At the end of June he had a slight apoplectiform stroke which was followed by two others in July and by a more severe one in September. On admission he was wasted and cachectic and had an air of hebetude, answering with difficulty questions which were repeated several times before he understood them. His memory was little affected except for recent events. His emotional qualities were considerably altered and he took little interest in his only child who was born a short time before his admission. His muscular power was much enfeebled. He could scarcely stand without support; his gait was staggering but not ataxic; he could not lift an object of any weight and on making an effort he trembled. The tendon reflexes were present. The right knee-jerk was a little stronger than the left and Babinski's sign was present on the right side. Speech was hesitating and accompanied by slight tremor of the lips and the tongue. The Argyll-Robertson sign was not present. While in hospital he twice lost consciousness for a short time. Lumbar puncture was performed on Nov. 20th and did not show any lymphocytosis. His mental condition rapidly deteriorated and the emaciation and the cachexia quickly progressed. Early in December a sacral bedsore formed and on the 11th of the month he died. The necropsy was performed after the injection of formol into the cranial cavity in order to harden the central nervous system. The cerebral hemispheres were abnormally large and the brain weighed 1575 grammes. The meninges were not thickened or adherent. On incising the cerebral hemispheres a large quantity of blood in the form of big drops, which were almost confluent, issued both from the centrum ovale and the central grey matter. The cerebellum was of normal size; its upper surface was flattened but the most striking deformity was shown on its lower surface. The amygdalar lobes formed two elongated projections almost two centimetres long on each side of the medulla and there was a deep groove due to the imprint of the foramen magnum. The spinal meninges were thickened and opaque posteriorly and there was sclerosis of the posterior and lateral columns of the cord. It is noteworthy that the condition of the brain was quite different from that usually described in general paralysis; the meninges were neither thickened nor adherent; instead of being diminished in volume the hemispheres were, in consequence of great congestion, much increased. The condition found in the cerebellum is exactly that described by M. Pierre Marie in cases of abundant cerebral hæmorrhage.[1] He explains the condition as an engagement of the amygdalar lobes of the cerebellum in the foramen magnum as the result of pressure of the cerebrum increased in volume by the hæmorrhage. He attributes the symptoms of apoplexy partly to the consequent compression of the medulla. The present case shows that intense cerebral congestion may produce the same result. In this connexion a case recently published by M. Faure-Beaulieu[2] is of interest. As the result of a large meningeal hæmorrhage on the left side not only was the cerebellum driven into the foramen magnum but by the same mechanism the hippocampal convolution was driven into the aperture in the tentorium cerebelli.

FEBRUARY AT HOME AND ABROAD.

THE search for the sun on the Mediterranean littoral and in Italy becomes yearly more unreasonable. Although February was less rigorous than January on the shores of the Mediterranean and in the south of Europe generally, it was a most disappointing month for all who expected either dry or warm weather. The temperature was continuously below the normal, while about the middle of the month there were several days of strong and bleak winds, with snow or sleety rain, and a frost that was only a little less severe than that which prevailed during the early days of January. The remainder of the month was wet in Italy and most often cloudy or dull in the Riviera. February of 1904 was very rainy and was also considered cold but the mean temperature for the month at Naples was 50·5°, at Rome 50·3°, at Biarritz 48·4°, and at the Nice Observatory 47·0°. The coast resorts of Portugal and Algeria were much milder last month than were the other southern regions. The coasts of Portugal were also dry, as is seen by the exceptionally small rainfall at Lisbon, but Algeria was decidedly wet, rain falling on almost every day after the 12th. As is nearly always the case, the resorts of Sicily had a higher temperature than had those in Italy and the Riviera; the general character of the weather, however, was extremely variable and frost was in evidence upon several occasions. The most frosty places were naturally those situated inland: thus at Florence there were as many as 11 nights on which the thermometer fell below 32°. On the 13th it sank to 21°, a lower point than at any station in the English midlands. Even Rome, much farther south and nearer the sea, had nine frosts—just the same number as central England—and Naples had more than any place in the southern counties of England. At the Nice observatory there was but little rain or snow and the sky was often clear. The nights and early mornings, however, were more frequently frosty than was the case in London. The only places quite free from frost were *Algiers*, *Lisbon*, *Scilly*, and *Jersey*, but at Torquay, London, and Biarritz the screened thermometer only just touched 32°. The warmth of the days at Torquay and Scilly was just equal to that experienced at Biarritz and Naples. The thermometrical values at Torquay and Naples were strikingly alike, the chief difference being in the absolute minimum, in which respect the English resort was far superior. With regard to the equability of temperature it is seen that none of the foreign resorts can compare with Jersey and the Scilly Isles and that, excepting Naples, not one of them was so equable as Nottingham and Bath. In England the month was extremely dry and sunny, the number of hours of bright sunshine recorded at Torquay being 35·6 more than during the corresponding month of 1904.

EYE DISEASE AND BLINDNESS IN THE PROVINCE OF PERM.

THE Ekaterinburg correspondent of the *Novoe Vremya* says that of the 3,100,000 inhabitants of the province of Perm there were in the year 1897 as many as 48,331 patients suffering from eye disease registered in the public hospitals. This, of course, does not show the total sufferings from this class of disease as many do not have recourse to medical aid. Most of the cases come from the foreign elements of the population, who live in the most revolting conditions of primitive filth. Ignorance, superstition, sorcery, and the belief in evil spirits prevail. Most of the foreign settlers live in smoke-blackened huts which are sometimes brushed out but never washed. To wash their faces they take water into their mouths and with the thus augmented saliva they rub their cheeks and eyes, the whole family using the same old rag to wipe it off. The population suffers mostly from scabies and eye disease. The Mahomedans do their regular appointed ablutions but the Baschkirs do not wash at all. Professor Adamyuk and Professor Evetski of the University of Kazan visited several villages of the immigrants and became satisfied as to the prevalence of trachoma. The inspection of some of the Krasno-Uphim schools revealed that 5½ per cent. of the Russian scholars were suffering from trachoma, whilst 21 per cent. of the Baschkir children and 39 per cent. of the Tcheremis children likewise suffered from it. On examination of the eyes of the pupils in the Perm women's gymnasium 10 per cent. of them were found to be affected with trachoma, whilst in the second class alone 20 per cent. were so afflicted. The most deplorable result of these eye troubles is, of course, blindness and here it reaches 4½ per cent., says the correspondent, whilst absolute blindness of both eyes reaches 1 per cent. of all the patients suffering from eye troubles. From these figures it appears that of all the 3,100,000 population of Perm the absolutely blind amount to 7500, or 25 blind to every 10,000 of the population. The Ural Medical Society, on the initiative of its president, Dr. A. Russkich, has built a free eye infirmary in Ekaterinburg called after an ophthalmic surgeon of the Urals, Dr. A. A. Misslaff. The society sought to interest every stratum of the population—towns, villages, manufacturers, and private persons, whose willing help made it possible to raise in two years without the slightest aid from the Government a hospital costing from 50,000 to 60,000 roubles. Some gave money, others land, and so on. The hospital is to be opened in the spring of this year.

MEDICAL SERVICE IN BASUTOLAND.

ATTACHED to the annual report for 1903–04 of the Government secretary of Basutoland just presented to Parliament is a report by the principal medical officer, Mr. Edward C. Long. He says that the general scope and efficiency of the medical work promise to be increased greatly by the completion of the new hospital at Maseru. This hospital, which was opened on May 28th, 1904, contains 28 beds and both its construction and equipment are all that could be desired. There is a growing need for hospital accommodation in the territory, for apart from the diseases ordinarily occurring in the country there is an increasing number of cases of acute disease amongst men returning from the labour centres. Such men often arrive at the camps in an exhausted condition and quite unfit to proceed to their homes. It is therefore highly desirable to have well-equipped hospitals at all the stations. Such a course would undoubtedly entail a considerable outlay both for construction and maintenance but it ought to be remembered that the Government hospitals and dispensaries are partly self-supporting. During the year under review the amount collected in out-patient fees, vaccination certificates, and so on, realised £1930 10*s*. This sum more than covered the cost of drugs and maintenance of patients (£1680 16*s*. 1*d*.). During the year the medical staff has responded to the request of the Cancer Research Committee for specimens of new growths and a considerable number of sections of tumours has been forwarded to the director. A short pamphlet on hygiene has been prepared and translated into Sesuto for use in the native schools. A conference of medical representatives, deputed by the Governments of Cape Colony, Natal, Transvaal, and Orange River Colony, was recently held in Maritzburg. At this conference certain recommendations were made with a view to a common action being taken by the South African Governments for the control of medicine, dentistry, and pharmacy. The support of the Basutoland Government was solicited towards that object and Mr. Long considers that some such control is desirable both as regards the present condition and the future development of the country. Besides the Government medical officers, who are mainly concerned in the administration of the Government dispensaries and hospitals, a few medical men have settled in the country and practise their profession among the natives. No evidence of proper qualifications is required from such medical men nor are their methods of practice subject to the control of any authority analogous to the medical councils in other colonies. As medical practice by duly qualified Europeans has an undoubted civilising influence, apart from the alleviation of suffering and the treatment and prevention of disease, it seems to Mr. Long to be desirable to guard, so far as possible, against any method in the practice of medicine which might hinder that civilising influence. There is also a very considerable trade in drugs carried on by Europeans who have had no medical training and in some instances large fees are received from natives for advice and medicine.

THE LONDON SCHOOL OF TROPICAL MEDICINE.

It is announced that Mr. Joseph Chamberlain will preside at a banquet to be held at the Hotel Cecil on May 10th in support of the London School of Tropical Medicine. The Duke of Marlborough is chairman of the dinner committee and Sir Nevile Lubbock and Sir Henry K. Davson, the chairman and vice-chairman of the West India Committee, will act as stewards. An important work is done by the schools of tropical medicine in training practitioners to recognise and to treat the special diseases of warm climates.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

The seventh lecture of the series[1] was delivered by Professor W. F. R. Weldon at University College, London, on Feb. 7th, the main topics discussed being the Mendelian doctrine of gametic purity, dominance, and reversal of dominance in the inheritance of characters. It is one thing, he said, to admit that the experimental results on the crossing of races of peas, referred to in the previous lecture, are as described, and another to assume that Mendel's hypothesis is the sole hypothesis which adequately formulates the facts. The doctrine of pure gametes cannot be reconciled with the vast body of facts and data of heredity in human families and races collected and published by Francis Galton and Karl Pearson. The more we know of the ancestry of man, of domestic animals such as dogs, and of cultivated plants the more accurate will be our prediction of what the progeny will be. Probably both views, the Galtonian and the Mendelian, will be reconciled in time in a wider generalisation of the facts of inheritance and descent—a larger theory of heredity. Yellow is the dominant factor in the first generation of hybrids obtained by the crossing of "pure" green and yellow seeded peas. This character of "dominance," said Professor Weldon, is comparable to that exhibited by each of a pair of separated blastomeres, which grows into a perfect but small larva in echinoderms and other animals mentioned in an earlier lecture. Whereas in two-celled union each blastomere gives rise to one-half (right and left sides) of the entire larval organism without dominance of one side or the other, the mechanical separation of the two blastomeres arouses the latent dominance in each and thus each is able to produce a complete larva. When hydra or a planarian worm is cut a quantitative restoration (regeneration) takes place of the missing parts, the power of reproduction becomes dominant locally about and at the site of lesion, and the lost organs or limbs are regenerated. Similarly cells changed by the removal of their normal connexions—e.g., the choroid cells of the frog's eye when the lens has been excised—regenerate and form a new lens. The power of regeneration in lower animals is so dominant that it can pass by inheritance from one generation to another for hundreds of generations. Reversal of dominance when it occurred does not always follow Mendel's formula. Thus Czermak of Vienna, who during the past few years has extensively investigated peas of various races, has obtained in his experiments results irreconcileable with Mendel's formula. Professor Weldon said that going over the same series of experiments he obtained results identical with those of Czermak. Thus when two well-marked races of peas were used—viz., (*a*) a smooth type of seed of nearly round or slightly oval contour and (*b*) a wrinkled type of seed of somewhat angular and irregular contour—the shape of the hybrid offspring of these varied according as to whether the pollen of (*a*) was employed to fertilise the flowers of (*b*) or *vice versâ*. The shape of the seeds varied in the hybrid progeny but not the colour. Again, whatever way the crossing was made these two separate types of hybrid issue (round and smooth or wrinkled and angular) each when self-fertilised reproduced "true." In other words, the segregation of allelomorphic characters (characters of colour which differed and were antagonistic) *did not occur in the first generation* of hybrid progeny on crossing and dominance showed itself —i.e., the occurrence of pure types—later. These facts, determined by both sets of observations, are contrary to Mendel's law. Czermak also crossed other peas of English and Austrian "races," both races being characterised, however, by yellow-coloured and rounded smooth seeds. The hybrids were round-seeded but the issue of these latter were uniformly wrinkled, a thing impossible, Professor Weldon remarked, on any Mendelian theory. They had in the foregoing instance a case of what Darwin called atavism, the reappearance of an ancestral character which long latent in both the races (English and Austrian) was roused into "dominance" by the shock of crossing and emerged into prominence, showing the "wrinkled" form. Many other experiments of Czermak confirmed the same conclusion as to atavism or reversion to the ancestral type. Such ancestry, says Professor Weldon, to which reversion takes place is not a very distant one. White mice marked with patches of purplish colour on the neck and rump when crossed with grey mice showed changes of colour and marking in the offspring which were exceedingly difficult to explain on any theory of gametic purity. When peas of a light or white-flowered "fancy" stock, the genealogical history of which showed descent from a long and distinctive purple ancestry, were crossed with another variety of similar colour the offspring reverted, sometimes very strongly, to the purple-coloured character of the ancestors. This ancestral dominance or reversion, concluded Professor Weldon, appears owing to the "shock" of crossing, and Czermak states that it is true that a very large number of ancestral characters are latent in every species and that any of them ma occasionally reappear.

ARE COLLIERY WARNINGS OBSERVED?

Colliery warnings are usually issued when the atmospheric pressure reaches a high mark on the barometer—that is, when anticyclonic conditions prevail. These warnings are commonly published in the newspapers but we have never been able to trace their source. Presumably they are issued by the Meteorological Office authorities. Nor have we been able to find out whether these warnings are seriously regarded. Last week a terrible explosion occurred in a Welsh colliery in which over 30 lives were lost. The disaster happened on Friday evening, March 10th. Now if the meteorological readings (published regularly in The Lancet) of last and this week be consulted it will be found that on March 8th the barometer stood at 30·08, on the 9th it fell to 29·5, on the 10th to 29·3, and on the 11th to 29·0. On the 10th the disaster took place. There was a fall, therefore, in the barometer of about one inch from March 8th to 11th, which amounts to a reduction of pressure equal to about half a pound to the square inch. As is well known combustible gas, chiefly marsh gas, occurs occluded in coal which is ready to issue into the workings of a mine as soon as a fall of the barometric column takes place. Hence colliery warnings are issued when the pressure is abnormally high in order to prepare the miners against the consequences of a sudden fall. The same liberation of gas takes place in the coal bunkers of a ship when the atmospheric pressure relaxes or when the temperature increases. In order to prevent the accumulation of this gas the bunkers are thoroughly ventilated. In the case of mines, similarly, ventilation is employed, *not only for the sake of the respiratory organs* of the colliers but also for removing combustible gases. It is an interesting fact that the fall of the barometer last week exactly preceded the explosion in the Welsh colliery which, so far as can be gathered, was due to gas and not to dust. It would be interesting to know: (1) whether these colliery warnings are regularly issued and, if so, by whom; and (2) whether they are heeded and the condition of the mine is ascertained in accordance with the warning.

---

[1] Abstracts of the first, second, third, fourth, fifth, and sixth lectures were published in The Lancet of Jan. 7th (p. 42) and 21st (p. 181), Feb. 4th (p. 307) and 25th (p. 512), and March 4th (p. 534) and 11th (p. 657), 1905, respectively.

PLAGUE IN SYDNEY IN 1903.

THE report drawn up by Dr. J. Ashburton Thompson, chief medical officer of the Government of New South Wales, on the third outbreak of plague at Sydney—i.e., that of 1903—has just reached us. The final case of the preceding outbreak occurred on June 12th, 1902, and the last plague-infected rat was taken on July 14th of the same year. In the outbreak of 1903 the first plague-infected rat was captured on May 12th and the last on August 15th. Two cases also occurred in man, the date of attack of Case 1 being June 17th and that of Case 2 July 2nd. Both these patients recovered. The report now before us deals with three periods—namely, the plague-free period from July 15th, 1902, to April 30th, 1903; the plague period from May 1st, 1903, to August 15th, 1903[1]; and finally a portion of the ensuing plague-free period from August 16th to Dec. 31st, 1903. During the first period systematic rat catching was carried on by the official municipal rat catching staff and 31,075 rodents were taken, of which 17,160 were bacteriologically examined. Not one of these was affected with plague, so that on April 30th, 1903, it appeared that for eight and a half months Sydney had been free from plague in its rats as it undoubtedly was from plague in man. Special measures were also taken during this period by the municipal health authorities to insure the protection of warehouses, food stores, and produce stores by making them less accessible to rats by means of stopping runs, substituting concrete flooring for wooden flooring, and the like. During the second period the same measures were undertaken but in addition a capitation fee was offered for rodents. The total number delivered was 14,671, and of these, which were all examined, 111 rats and 50 mice were found to be plague-infected. Of the two cases of plague which occurred during this period in man the source of infection in Case 1 remained undiscovered. In Case 2 infection was presumably due to rats. During this period plague rats were also discovered on a ship which had come from Buenos Ayrés. The general trend of the report shows that in this oubreak, as in the two former, the rat was the sole source of infection for man, but the relation of the rat to epidemic plague must still be generally considered as obscure. However, as Dr. Thompson points out, intelligent action as regards destruction of rats, their examination and identification of any illness from which they may suffer, together with careful cleansing of premises, are, as shown by the history of this outbreak, measures of the greatest use in limiting and in checking an *epizootic*.

PRESENTATION TO DR. WILLIAM W. IRELAND.

ON March 4th, in the Royal College of Physicians of Edinburgh, Dr. William W. Ireland was presented with an illuminated address and a cheque on the occasion of the fiftieth anniversary of his medical graduation. Dr. John Playfair, the President of the College, occupied the chair and a considerable proportion of the company consisted of alienists, including the Scottish Commissioners in Lunacy and a number of asylum superintendents from various parts of the country. Dr. Ireland commenced his professional life in 1855 by graduating as M.D. at the University of Edinburgh and then entered the medical service of the Honourable East India Company. During the Mutiny of 1857 he received a wound which prevented him from undertaking active work during the next ten years. Eventually, however, he joined the Scottish National Institution for the Education of Imbecile Children situated at Larbert in Stirlingshire, where he made excellent use of his opportunities for studying the mental diseases of children and accomplished much literary work, both original productions and translations from the writings of continental authorities. Dr. T. S. Clouston, of the Royal Lunatic Asylum, Edinburgh, in making the presentation, said that Dr. Ireland had opened up a new path in biography by his application of medico-psychology and the effects of heredity in the elucidation of the lives of men historically eminent. Some of his publications, such as "The Blot upon the Brain" and "Through the Ivory Gate," were not only scientific but were also vivid and interesting to all intelligent readers, whilst his treatise on "The Mental Affections of Children" was the standard work on developmental defects of the mind. After Dr. Ireland had suitably acknowledged the presentation Dr. David Yellowlees, formerly superintendent of the Royal Lunatic Asylum, Glasgow, in proposing a vote of thanks to the presentation committee, of which Dr. John Thomson was the secretary, also paid a high tribute to the value of Dr. Ireland's work.

ACUTE ASCENDING PARALYSIS IN CASES OF CHRONIC CYSTITIS.

THE theories as to the etiology of many affections of the spinal cord were *until comparatively recently very unsatisfactory* but when it began to be recognised that some of these morbid conditions were the direct effect of such a definite chemical poison as lead it was difficult to avoid the very natural inference that other lesions of the spinal cord were the result of more obscure toxic agents. Thus some of these spinal paralyses appear to be produced by the toxins of the acute specific fevers and others are believed to be connected with the toxins of syphilis. Dr. T. J. Walker of Peterborough contributed a paper to THE LANCET of March 11th, p 636, in which he recounted the essential particulars of three cases under his care. In each of the three there was a history of long-continued cystitis, not improbably accompanied by septic changes in the higher urinary tract; suddenly paralysis commenced in the lower limbs, rapidly spread upwards, and death occurred, in two cases 18 hours, and in one case 48 hours, after the onset of the paralysis. These acute ascending paralyses appear to be examples of Landry's paralysis but chronic cystitis has never been given as an etiological factor in that disease and all the text-books are silent on the matter. Hence the importance of Dr. Walker's observations. It is true that Stanley in 1833 described a paraplegia arising in a patient suffering from distension of the urinary bladder, yet the case he reported is by no means on all fours with those which Dr. Walker has described, for at the time of death the paralysis had not gone above the waist. It is indubitable that in chronic septic processes of the urinary passages many toxins are formed and we can easily understand that the sudden absorption of some such toxin might produce an acute ascending paraplegia. Now that attention has been drawn to the association of these two conditions many cases will probably be noted and it may well be that such a causal nexus will be found to be far from rare. One of the most important factors in scientific progress is the recognition of hitherto unsuspected associations of phenomena.

---

[1] This period is taken from May 1st, although the first plague-infected rat was taken on May 12th, "for simplification of the analysis in view of the probability that the epizootic had begun some unascertainable number of days before the date of its discovery."

A SALE OF WHISKY BILL.

WE understand that Sir Herbert Maxwell has presented a new Sale of Whisky Bill to the House of Commons. We believe the Bill seeks to obtain the same protection for purchasers of whisky as did the previous Bill, the clauses of which were dealt with about a year ago in a leading article in THE LANCET.[1] The Bill provides chiefly that a clear statement shall be made to purchasers as to the materials from which whisky has been made. It formerly applied to Great Britain but Ireland is now included and the measure will probably receive the support of the Irish Members.

THE SOUTH AFRICAN MEDICAL CONGRESS.

OUR readers may be again reminded that the South African Medical Congress will be held at Pietermaritzburg, Natal, from June 12th to 17th next inclusive, under the auspices of the Natal branch of the British Medical Association. Dr. James Hyslop, D.S.O., of Pietermaritzburg is the president and Dr. Samuel G. Campbell of Durban is the vice-president, while the honorary joint general secretaries are Dr. D. Campbell Watt, Pietermaritzburg, and Dr. W. Watkins-Pitchford, Pietermaritzburg. The names of the various sections and their secretaries were detailed in THE LANCET of August 27th, 1904, p. 625. The following dates have been assigned to the proceedings of the various sections—viz., Section (1), subjects of general interest, Monday, June 12th; (2) medical section, June 13th; (3) surgical section and (4) gynæcology and obstetrics, June 14th; (5) public health, June 15th; and (6) special subjects section, June 16th. On Saturday, June 17th, excursions will be made to the battle-fields, Ladysmith, to Durban and its harbour, and to the waterworks, Henley. On June 12th the Congress will be officially opened by His Excellency the Governor and in the afternoon of the following day there will be a demonstration at the Government Bacteriological Laboratory. On June 14th, in the evening, the Mayor will hold a reception and on the afternoon of June 15th there will be a garden party at Government House and in the evening the President will hold an "at home" at the Natal Government Asylum, of which he is the medical superintendent. On the afternoon of the following day a visit will be paid to Nel's Rust creamery and in the evening the Congress banquet will take place. A list of hotels is given the tariff of which ranges from 8*s.* 6*d.* to 12*s.* 6*d.* per day. The Natal Government has arranged that members of the Congress may travel by rail at reduced fares and the Union Castle Mail Steamship Company has consented to grant a reduction of 20 per cent. on the usual fares to *bonâ-fide* members of the Congress embarking at Cape Town, Algoa Bay, and East London. The Union Castle Steamship Company states in "The Guide to South Africa" that the distance in nautical miles from London to Durban is 6993 miles. Pietermaritzburg is about 70 miles north-west by west of Durban. The journey thither from London occupies from three to four weeks.

SEÑOR MANUEL GARCIA'S CENTENARY.

AS announced in THE LANCET of Jan. 28th, the celebration of Señor Manuel Garcia's centenary will take place to-day (Friday, March 17th). The programme has now been definitely arranged as follows. A meeting will be held at noon at 20, Hanover-square, at which congratulatory addresses and messages will be delivered in the following order: messages from the King of Spain and the German Emperor, address from the Royal Society of London, message from the Prussian Academy of Sciences, addresses from the Universities of Königsberg, Manchester, and Heidelberg, address from old pupils, addresses from the Royal Academy of Music and the Royal College of Music, and addresses and messages from the following laryngological societies: American Laryngological Association, Belgian Society of Oto-Rhino-Laryngology, Berlin Laryngological Society, British Laryngo-Oto-Rhinological Association, Danish Laryngological Society, French and Italian Laryngo-Rhino-Otological Societies, London Laryngological Society, Netherlands Laryngo-Oto-Rhinological Society, the Paris, Rhenish-Westphalian, St. Petersburg, and South German Laryngological Societies, Spanish Laryngo-Oto-Rhinological Society, and the Vienna, Warsaw, and West German Laryngological Societies. In conclusion, the centenarian's portrait, painted by Mr. John Sargent, R.A., and subscribed for by international contributions, will be handed to him. In the afternoon, at 3 P.M., there will be a special meeting of the London Laryngological Society at which the foreign visitors will have the opportunity of seeing a number of interesting cases and specimens. In the evening, at 7.30, a banquet will take place at the Hotel Cecil at which Señor Garcia is expected to be present. The toasts will be but three, namely—"The King," "Señor Garcia," and "The Foreign Visitors." It is hoped that Señor Garcia will reply to the toast of his health. After the dinner a selection of music will be given by a number of eminent artists who have kindly offered their services.

THE medical officer of health of the Cape Colony states that for the week ending Feb. 18th the condition of the colony as regards plague was as follows. No case of plague in man or other animal was discovered in any district of the colony during the week. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on March 10th states that for the week ending March 9th there were 3 cases of plague reported and 1 death occurred from the disease.

The Duchess of Albany has intimated her intention of attending the annual meeting of the governors of the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, W.C., to be held at the hospital on March 21st, at 3 P.M.

AT a meeting of the Hunterian Society to be held at the London Institution, Finsbury-circus, E.C., on March 22nd, a discussion upon Influenza will be opened by Professor T. C. Allbutt, F.R.S. The discussion, which is open to all members of the medical profession, will be continued on April 26th, and amongst those who have promised to take a part in it are Dr. H. Franklin Parsons, Dr. F. J. Smith, Dr. I. Burney Yeo, and Dr. T. Glover Lyon.

THE Education Committee of the London County Council submitted an important report to the Council at the meeting on Tuesday last in respect of the *medical supervision* of the Council's board schools. The report which provided for more complete medical inspection involved an increased expenditure of over £2000 per annum and consideration of it was postponed.

---

[1] THE LANCET, March 19th, 1904, p. 816.

THE King has sanctioned the following promotion in the Order of the Hospital of St. John of Jerusalem in England—viz., Joseph Dallas Pratt, M.D. Dub., F.R.C.S. Irel. (from *Honorary Associate*), to be Knight of Grace.

Mr. G. H. Makins, C.B., F.R.C.S. Eng., and Mr. Charters J. Symonds, M.S. Lond., F.R.C.S. Eng., have joined the consulting staff of the Bolingbroke Hospital, Wandsworth Common, S.W.

MEDICINE AND THE LAW.

The Storage of Flour.

THE Paddington borough council appeared in answer to a summons at the Marylebone police court on March 3rd, the complainant being a baker whose underground bakehouse the council had refused to license because he would not use a kitchen exclusively as a store for his flour. Mr. Plowden acceded to the complainant's application and granted him a licence on the ground that the lighting, ventilation, and construction of the bakehouse only were the concern of the public authority in the matter. It might have been expected that if the learned magistrate felt himself constrained to take this view of the law he would have done so with some regret but Mr. Plowden, on the contrary, regarded the conduct of the council as an act of officious interference with the baker's liberty of action. "What could it matter to the council," he asked, "where a poor baker kept his flour?" To this the medical officer of health replied by pointing out that flour not kept in a proper place will go sour. He might have added that it mattered nothing at all to the council but that it made a great deal of difference to the poor people whose circumstances compelled them to buy and to eat the bread. In giving his decision Mr. Plowden is reported as having said further: "You cannot determine where he shall put his flour any more than you can determine where I put my drawing-room furniture. I call it most meddlesome and officious interference and it seems to me it is pressing the whole purport of the section of the Act extravagantly. Where he keeps his flour matters nothing." The 101st section of the Factory and Workshops Act, 1901, provides that "an underground bakehouse shall not be certified as suitable unless the district council is satisfied that it is suitable as regards construction, light, ventilation, and in all other respects." Upon what section of an Act of Parliament or upon what other authority Mr. Plowden relied when he gave the remarkable and unfortunate decision quoted above does not appear in the reports published in the daily newspapers. It is not easy to believe that the legislature intended to confine the regulation of the bakehouse to the ventilation and construction of the actual baking room (a term specifically used where the baking room only is meant), and that it viewed with indifference the fact that the baking room might be suitable while the flour might be kept in a place swarming with vermin or serving the purposes of a latrine.

Antivaccinationists in the Educated Classes.

At Bow-street Sir Walter John Grove was summoned recently and fined 20*s.* with 23*s.* costs for refusing to comply with an order previously obtained that he should have his child vaccinated. The solicitor for the prosecution mentioned that he had received a letter from the defendant, who was not present, in which he said that personally he had no objection to having his child vaccinated and, indeed, wished it to be done, but that Lady Grove, being an antivaccinationist, absolutely declined. Sir Walter Grove was accordingly fined, as being the parent legally if not morally responsible in the matter. It is to be hoped that the children of Lady Grove will not at some future period learn to regret bitterly the attitude of their mother in needlessly exposing them to the ravages of a dangerous and disfiguring disease or the want of authority of their father in his own household.

The Coroner, the Medical Man, and the Pathologist.

A typical instance of the attitude adopted by the coroner in the South-Western district of London towards the medical men practising within his jurisdiction is to be found in a case which occurred recently. A local medical practitioner was hurriedly summoned to attend "a woman in a fit." He found a stout woman lying on the floor on her back with a cushion under her head. He thought that he could detect slight movements of the chest wall but he could feel no pulse and could not with the aid of the stethoscope discover either heart beat or respiration. Her conjunctivæ had become insensible to touch. He at once took the trouble to notify the police and to suggest that the coroner should be informed, giving his name and address. Nevertheless, strange as it may seem, he received no summons to attend the inquest as a witness and when he voluntarily attended and offered to give evidence was told by the deputy-coroner that his "worthy chief," Mr. Troutbeck, had settled the matter. The post-mortem examination was made by Dr. L. Freyberger. Presumably Mr. Troutbeck will continue to follow the policy which he has adopted until the step recommended frequently in THE LANCET is taken and objection is made to the auditor of the County Council's accounts in respect of fees paid for medical evidence at inquests which are not sanctioned by the Coroners Act.

Limited Liability Companies and Medical or Dental Practice.

An excellent method has apparently been discovered by the Irish branch of the British Dental Association for dealing with the offence of dental practice by unqualified persons under the cloak of a limited company with a title implying qualification to practise dentistry. The difficulty of convicting criminally in such cases lies in this, that a company cannot be registered as a dentist, so that it cannot logically and legally be said to commit the offence of pretending so to be registered. Further, the individual performing the operation is not the company so that he often persuades the easily misled local magistrate that it is not he who has used titles implying registration and the non liability of the company is used by the advocate to befog the issues generally. The Irish branch of the British Dental Association has accordingly tried a new plan and, invoking the aid of the Attorney-General, has asked for, and obtained, an injunction against one of these bogus companies in the Chancery Division at Dublin. The defendants selected practised under the audacious title, "Mr Appleton, Surgeon Dentist, Limited." The ground of the application was that the whole matter constituted a dangerous fraud upon the public and upon the dental branch of the medical profession. The whole of the facts connected with the registration of such companies in general and with that of the company before the court [illegible]

K.C., in applying for the injunction had been in no way too strongly worded; he had spoken of an audacious fraud and the facts constituted an audacious fraud. It was a matter affecting the whole public and it was no answer to an application for an injunction to say that the offence was an indictable misdemeanour. The Attorney-General was entitled to apply to stop the misdemeanour and he was entitled to succeed. It is hardly necessary to point out that the course thus adopted may mark an epoch in the efforts of the medical and the dental professions to deal with quackery and that the invoking of the aid of the Court of Chancery, if somewhat cumbersome and costly, may prove a more efficient method than the *police-court summons* in other cases besides those where the bogus limited company is used as a stalking horse for the unwary public.

The Midwives Act.

The actual meaning of that part of the Midwives Act [illegible] March 31st, 1905, should not [illegible] no woman will be allowed to call herself a midwife or to use any other name to make people believe she is specially qualified to practise as a midwife unless her name is on the midwives roll kept by the Central Midwives Board. Under the Act any woman who has been for one year in *bonâ fide* practice as a midwife before the date on which the Act was passed (that is to say, before July, 1902) and who can give satisfactory references to character, may, before March 31st, 1905, claim to have her name put on the roll.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER IV.[1]

THE GRIEVANCES OF THE MEDICAL PROFESSION.

The Diversity of the Grievances.—The Consulting Physician and Surgeon.—The Growth of Specialism.—The Grievances of the General Practitioner.—Medical Aid Associations.

WHEN we survey the present state of the medical profession in detail, so as to seek out the advantages enjoyed by some classes and the grievances endured by others, we are at once struck with the varied opportunities that the profession holds out to men of different bents of mind. The consulting physician, the operating surgeon, the general practitioner, the holder of purely scientific appointments, the holder of sanitary and municipal appointments, the medical officer in the navy, in the army, in the Indian army, and in the colonial service—the careers of all these differ entirely. For some life will be essentially adventurous; for others it will be spent in two or three wards, an operating theatre, and a consulting room. Some will be the trusted friends of the great and the wise, so that the most exclusive doors will be open to them; others will serve under authorities and municipalities composed of men whose education and position are not equal to their own; and some must live the life of the poor with the poor. The sportsman can indulge his proclivities in moderation while discharging his professional duties with zeal, and small will be his chances of success if he interchanges the zeal and the moderation. The man who loves the study of his fellows has social and psychological problems unrolled before him from hour to hour—he sees naked souls as well as naked bodies and has to take the treatment of both into his consideration; while he whose sympathies are rather with the theory than with the practice of his art can exert his energies in the class room or laboratory without coming into collision with the public. All sorts of persons in all sorts of methods and under all sorts of skies can carry on the profession of medicine, so that there need not be many to whom the medical life is irksome. There will be an unfortunate few, who, being by nature designed for work of one kind, have by stress of circumstances been forced into a different groove. Probably they did not discover their own tastes until it was too late to work in the necessary direction and this error is a very difficult one to rectify, whatever calling in life a man may adopt. But, speaking generally, the profession of medicine has this first advantage for its British disciples; it offers a career that can be varied to suit all tastes. A high percentage of the followers of medicine attain to a fair degree of success and the total failures are comparatively infrequent, and no man need follow a thoroughly uncongenial employment as a medical man because of the great diversity of careers that is open to him.

These three things must always be remembered, for while many circumstances may be held to detract from the medical life, these three things, whatever those circumstances, establish it as a good life offering chances to a man with brains and energies to take advantage of them—chances of choosing a proper sphere of labour and of remaining to some extent master of his own career, while obeying the conventions and the restrictions entailed by modern civilisation. And to these must be added as the supreme pleasure of the practice of medicine, counteracting numberless disadvantages and annulling the greatest trials, the sense of being a member of a high and noble calling. Though many causes are at work, as we know too well, such as the prevalence of quackery, the abuse of hospitals, the commercial societies sweating the medical man, which all tend to make the medical life a hard one, this sense abides with us and supports us. And though busy days are followed by busy nights, there are rewards of infinite sweetness. What though the medical man occasionally meets with meanness, rudeness, and ingratitude. These things are not the rule and to no other body of men is it given so often to deserve the heartfelt thanks of their fellows, to be brothers to the weak and helpers to the fallen. The feeling that merely to do the duty of the day is to discharge functions of the greatest gravity and to cope with situations of the most delicate responsibility is ennobling. No other pursuit can equal ours in variety and interest and when followed conscientiously none will bring to the mind so unalloyed a sense of pleasure.

But none the less the grievances of the medical profession are very real, as are the various circumstances which militate against the progress of medicine and which by depressing the scientific, material, and social status of the practitioner make him a less useful instrument for the safeguarding of the public. That these grievances are of many kinds is assured by the fact that there are many kinds of medical practice. And if some of them seem common to all sections of medical practice while others seem peculiar to one section or another, it must be remembered that the subdivisions upon which a little insistence has just been placed are subdivisions of practice only; the broad aims of every member of the medical profession are the same, his ideals are the same, and his responsibilities to the public are the same; and whatever interferes with the due development of the utility of one branch of the profession affects the whole professional body.

THE POSITION OF THE MODERN CONSULTANT.

The consulting physician and the consulting surgeon represent the fine flower of success in the medical profession. They are the class in Sir James Paget's classification for whom the designation of "very distinguished success" is reserved, so that not much time need be occupied in detailing their chances of ill-success. These are largely comparative and are expressed by saying that times have altered much of late and that here competition has become severer. When the class from which hospital physicians are drawn was a very small one, and when the "pure" surgeon was followed in his appointment and practice by favoured pupils, the lack of rivalry among the consulting class was conspicuous. It was insured by an early line of demarcation being drawn between those who might and those who might not hope to attain to leadership in the profession, and we do not suppose that there exists anyone sufficiently illiberal to regret the ancient order. But with the multiplication of universities, the growth of provincial medical schools, and the complete abolition of direct and indirect traffic in hospital appointments there has come a marked increase in the number of candidates for the highest professional honours. Round every general hospital to which a medical school is attached a band of young men await the opening for which they have fully equipped themselves. But to obtain their hope does not necessarily mean success. For those who gain staff appointments or hospital appointments soon find that the struggle upon which they have embarked is a severe one and that the trials of competition are not over because they have succeeded in getting on the bottom rung of the ladder that leads up to distinguished success. There are so many others in the same position and the number continues to grow as the number of hospital appointments, whether at general or special hospitals, grows. The young general consulting physician, in England, Scotland, or Ireland alike, finds it very hard, as a rule, to earn enough money to live until the public are aware of his existence, while the teaching appointments upon which he would have relied in days gone by are at many of the best centres of medical education no longer lucrative. If the plight of the young consulting surgeon is better, because in the matter of operations the public is not so loth to trust a young man as where medicine is concerned, still he also feels the strain of competition and the loss of emolument for his educational labours. When the science of medicine was much simpler, and when the education of the medical student was a much less costly thing, the fees paid to a medical school were in excess of the cost to the school of supplying the student with the necessary facilities for education. The surplus was divided among such of the medical staff of the hospital as held teaching appointments. And although it is now some time since lectureships at the medical schools have been worth substantial sums, it is only in comparatively recent years that the position has been established that a large part of the education of the medical student has to be carried on by gratuitous effort. This plight has, of course, been reached mainly on account of the great increase in the expense to the medical schools that results from the developments of physiology and bacteriology. Expensive practical courses have to be arranged, expensive laboratories have been built, and the result is that medical schools, which in many instances draw on the funds of their hospitals, cannot pay any of their lecturers adequately, and often do not attempt to pay them at all.

---

[1] Chapters I., II., and III. were published in THE LANCET of Feb. 18th (p. 447), Feb. 25th (p. 517), and March 4th (p. 593), 1905, respectively.

The loss of valuable income obtained by tuition during the critical early time of professional life falls now upon the consultant when he has to bear the strain of a new and increasing class of competition—the competition of the special hospitals. The growth of special hospitals has created a large increase in consultants of the specialist type, and the public believe implicitly that the medical man ought to be a specialist. There is some reason in the view, just as there are powerful arguments against it. The developments of medicine and surgery, and the opportunities for interchange of knowledge afforded by the multiplication of medical societies and medical journals, have made it impossible for any medical man to keep level with the ramifications of our science in special directions, and as a consequence it is now quite usual for a consultant to make choice of a line along which he proposes to work. If he is at a general hospital he becomes associated in the minds of his colleagues and of his pupils with cases of a certain sort, the wards of his hospital give him scope for clinical research, and its records enable him to interpret the lessons of the past by the knowledge of the present. If he is at a special hospital, though he has not the same opportunity of keeping in his memory the general rules by which special problems must often be solved, still he has probably more valuable material, material which more immediately and more frequently illustrates the recurring difficulties of treatment. All this implies that along any groove of medicine competition among the consulting authorities is more than doubled, while this does not tell the complete tale. There are special hospitals which foster hospital abuse by having no adequate regulations to prevent the well-to-do public from obtaining advice at their out-patient departments in return for small sums of money. These institutions undoubtedly deprive the consulting physicians and surgeons of much professional work for which they should receive remuneration and it is regrettable to think that in many cases the evil has arisen through the direct action of medical men. Hospital abuse is a subject to which further reference is about to be made but it is well to point out here that it weighs sometimes as heavily against the consultant as against the general practitioner, for this aspect of the matter is frequently missed.

Through competition, fair and unfair, and through the spendthrift policy entailed upon the medical schools by the educational conditions of to-day the consulting physician and the consulting surgeon at the beginning of their careers have often a severe struggle. Yet when we have said this the fact remains that they form the really successful members of our profession. And so far from succeeding to that position by the favour of extrinsic circumstances, as would have been their lucky lot in days not long gone by, every step has to be won by competition. Every post is wrested from men apparently of equal merit and hard on the heels of every holder of a post treads another ready to take his place. And the posts so striven for are practically unpaid ones, while the public save in exceptional circumstances are apt to be many years before they are prepared to remedy the pecuniary deficiency. Success is only won by incessant hard work, self-denial, and courage, for the number of cases of genuine and abiding success that follow upon irregular methods, such as self-advertisement, is, we are proud to know, small.

THE POSITION OF THE GENERAL PRACTITIONER.

The grievances of the general practitioner are much more numerous than those of the consulting physician or surgeon. So much prominence has been given to them in the pages of the medical journals that in the opinion of some people—those people who are not themselves sufferers—they have been made to wear an unduly important face. As a matter of fact, the measure of the hardships which surround and impede the life of the general practitioner has never been realised properly either by the public or by the medical profession as a whole. This want of appreciation by the public of the troubles affecting those who live more than any other section of the community by the alleviation of the troubles of others has been brought about in an obvious manner. Medical men have rarely made a common cause against abuses which threaten or assail them and those who have done so have acted generally in a half-hearted manner, feeling that they are without the material or moral support of their natural leaders, the great figureheads of medicine, and sore at being termed trade unionists. The public are not conspicuously in agreement with the aims of medicine and have not the trust in their medical advisers that they had a generation ago. The public are educated to the point of distrust in what they cannot understand, but no further; and a certain section of the press, having a mental endowment not much superior to its *clientèle*, makes a business of fostering the inevitable misunderstandings. It is not to be regretted that the public have lost blind faith, but it is unfortunate that they have not acquired, with their wider mental horizon, a more reasonable grounding in scientific facts. The general practitioner has to meet his adverse circumstances with a proportion of the public ready to regard him distrustfully, with no effective methods of combination, and without influential leadership. The grievances under which he suffers to which special allusion is now to be made—namely, the evil of contract practice and the prevalence of hospital abuse—are of a material kind. Primarily, that is to say, they affect the purse of the medical man and his status in society. They are the things that directly or indirectly cause him to be underpaid; and from them the situation arises that either he puts up with imposition, which gives him a constant sense of soreness and never wins him the least appreciation from the public, or he resists it, in which case he is made to appear a grasping and extortionate person. Also he soon discovers that in the majority of cases he is quite unable, through lack of combination with his fellows, to gain anything substantial by resistance.

Medical Aid Associations.

It is constantly assumed by medical men, when stung into writing or speaking of their social or professional grievances, that the medical professional is overcrowded but the figures which have been given in the previous chapter do not bear out this view. The overcrowding is only partial and arises from the facts that too many medical men want to do the same thing and that too few are trained in the proper way to do anything different. So that in certain places competition becomes over-acute with an inevitable cheapening of medical service. Undoubtedly there are too many young medical men in England who desire to start in independent practice, preferably in a town, immediately they have placed their names on the Medical Register. They are not willing to act as assistants; the various services have no great attraction for them; they are without capital. In this section of the medical profession there is overcrowding and the public have taken advantage of the fact. For of late years a movement among laymen has introduced into medical practice a new and disagreeable feature. The public, through so-called medical aid associations, have attempted by means of strong organisations to capture and to exploit medical service. It is about 10 or 12 years since certain members of the medical profession, mostly in possession of middle-class practices in large towns, began to be aware of the danger that was threatening them, through such bodies as the Manchester Unity of Oddfellows, the Foresters, the Druids, the Temperance Society of the Rechabites, the Industrial Assurance Company, Limited, the National Medical Aid Society, and many local associations. Complaints were made now from this town and now from that and a few persons well versed in medical politics knew that serious general trouble was arising. Local medical societies and branch meetings of the British Medical Association were addressed by aggrieved members and a few out spoken letters made their appearance in the press. But for the most part the injured persons contented themselves with grumbling; but little attempt was made to diagnose the exact condition and to treat the cause, and no leader arose to formulate any policy of defence or reprisal. The medical profession as a whole hardly realised the extent to which they were being exploited until "The Battle of the Clubs" (as the struggle has been called) was started at Cork. The issues at Cork were exceedingly simple. The medical men of the city found that their private practices were falling off and those of them who were medical officers to clubs had no difficulty in appreciating the reason. An undue proportion of the substantial citizens, large tradesmen, employers of labour, and salaried clerks were joining the medical clubs and were demanding to be treated on the same terms as artisans and labourers, and even sought that a small yearly fee should cover attendance upon every member of the subscriber's family. The medical officers to the clubs protested. They required that persons in a proper position to pay fees for medical service should pay them and should not accept unwilling charity at the hands of medical men often in poorer circumstances than themselves. The clubs paid no attention to the protests and the medical men resigned their appointments and formed themselves into an association. They refused to work again for the clubs save at enhanced rates and with proper opportunities of deciding who were and who were *not* fitting objects for medical charity. The clubs imported persons whom the Cork medical men refused to meet as professional brethren. Upon this position being reached THE LANCET instituted an inquiry into the position of the medical profession in regard to the societies which in an increasing number of districts are now providing medical aid for the sick poor. Many complaints of divers sorts had been uttered but the struggle at Cork presented definite issues upon which the battle might be fought elsewhere. At Cork the medical men won the day, the imported practitioners making little headway in the city and the patients in large quantities deserting the clubs, which showed that effective resistance could be made. THE LANCET despatched a special commissioner to various medical centres in the kingdom who made reports of great interest and convincing frankness.[2] He showed in how many ways the evils of contract practice had grown up. Medical men, who already knew from personal experience something of the matter, were reinforced in their sense of the reality of their grievances by finding them shared with so many of their professional brethren, while medical men into whose ken such matters had never entered became acquainted with the troubles of a large section of their colleagues and so were prepared with valuable sympathy.

The articles showed the organisations to vary greatly in their scope and design. Some of the societies have as their primary objects schemes for life assurance and only add to these their project for medical aid as an inducement to the public to enter their fold. They form an example of the way in which a bad influence may spread, for certain life assurance offices, not over careful in their methods, having commenced touting for custom among the poor in this fashion, other and better offices have declared themselves compelled to follow suit. Some of the schemes to secure for the public medical attendance at low rates—a very worthy programme if it can be carried through without the oppression of other people—are devised, as far as the medical officer is concerned, with cynical callousness. The medical officer's salary is small, his work immense, and the conditions under which it has to be done preclude him from exercising his calling scientifically. Some of the associations are well managed in that an effective attempt is made to insure that only the truly necessitous shall be the recipients of medical charity. Some are uncommonly ill-managed in that all persons, no matter what their condition of health or their means, are invited to enrol themselves that they may be treated medically for *1d.* a week, drugs included. In certain of these institutions the management of the association having been, and remaining, entirely in lay hands the interests of the medical officers suffer particularly severely. The patients who might reasonably have been expected to pay *them* as private clients are not ashamed to join the charitable associations—charitable to all save the medical men—and often want to have their wives, children, immediate relations, and occasionally the stranger within their gates treated in return for one payment. Many a medical man has found his private practice drifting into the hands of these bodies. The associations take his humbler patients and place this issue before him—will he attend *their* members in *their* way at *their* time under *their* rules for *their* fees, or will he have a salaried rival brought in against him? Some medical men have surrendered, others, particularly where there was a chance of combination against oppression, have held out. Where the middle-class patients, pauperising themselves, listen to the blandishments of the agents of the association and join the clubs in spite of their ability to pay their medical men proper fees, the contest has gone at first against the medical men. On the other hand, where the medical men by presenting an organised resistance have been able to keep the sympathy of the public on their side, the imported medical men have failed to fulfil their tasks and the clubs have suffered badly.

The ethical side of the situation must not be lost sight of. The manifest impropriety of medical men taking service under lay masters has led to an important development. It was, and is, the habit of certain medical aid associations to employ canvassers who by vaunting the talent of their salaried medical officers press the claims of their institution on the patients of other medical men. When this became known it was immediately seen that such a proceeding constituted a professional offence, inasmuch as a medical man was doing, or permitting to be done for him through the agency of another, a thing which could be construed as advertisement, and advertisement is an "infamous" act in a professional sense. The General Medical Council took this view when it decided that the use of agents and canvassing to secure patients must be condemned. This support from the disciplinary tribunal of the profession put heart into the resistance to the exploiting tactics of the medical aid associations, with the result that many local organisations of medical men now exist for the purpose of taking combined action in support of claims for fair remuneration. There is no need to say more upon a subject which has been so much discussed, but it is well to point out that the General Medical Council remains unchanged in opinion as to the undesirability—to use no stronger word—of medical men serving lay associations upon unprofessional conditions.

(To be continued.)

ALCOHOL AND COMMERCIAL EFFICIENCY.

AT a conference of business men held at the Mansion House on March 8th, the LORD MAYOR presiding, Sir VICTOR HORSLEY made the following remarks:—

"When Mr. Ray first told me of the proposed title of this gathering this afternoon I was at some loss, from the scientific point of view, as to how to present the case before you. We have no experiments in our records of so many commercial men who are abstainers on the one hand and so many who are non-abstainers on the other to show what is the efficiency of those two classes of men respectively. But, my Lord, I take it that what we mean by commercial efficiency is economical expenditure to obtain a profitable return. Now, from the scientific standpoint it is very possible for me to make such a statement to you as shall be applicable to the everyday life of a commercial man. Alcohol is peculiar; there is something extraordinarily special about it because it is not essential to life. And there is no other substance, there is no other thing that we have to do with in this world upon which there is such an enormous national expenditure which is not an essential to life. Now the medical profession hold that it is one of the greatest evils to the nation, this non-essential. I suggest to you that socially and commercially it is a far greater evil than anything that the medical profession have considered it to be. It is useless to [illegible] eminent man to a meeting of thi [illegible] the Ex [illegible] ith un [illegible] the commonest cause of poverty and crime. If here we have a substance which is non-essential to life, is the commonest cause of poverty and of crime and one of the commonest causes of disease and of vice, then surely the time has come for this great city to review the situation from a commercial or economic standpoint. It is an ordinary idea that it is only the inefficient, the social failures, who find their way into the workhouse and the gaol. It is not only the persons who fail at the outset who drift that way. But I would like to say that the reason why people pass to the workhouse and the gaol is because of a common everyday belief that this non-essential to life is a beneficial substance, the common everyday belief that to the well-balanced mind there is no harm but that there is actually some profit in taking alcohol. If we speak to the ordinary man in the street he tells us at once, 'I do not drink, I take a little at my meals.' But in his answer, I submit to you that he is not considering the question of the nation at large, he is simply considering whether this substance does him any harm. And again, I submit to you that from an economic standpoint we have no moral right to support the continued use of something which, on the average and on the whole, is a source of loss and not profit to the nation at large. Of the annual expenditure, the direct outlay—that for which we are given to understand by popular belief there is some return—the annual expenditure of from £160,000,000 to £180,000,000 I have very little to say, it is all thrown clean away. But I want to impress upon you that that is only one part of the bill. Take Mr. Ritchie's statement in the House. We have to add to that the cost of most of the crime, the cost of most of the poverty, most of the premature death of bread-winners, and we have to add, from the medical point of view, that great tax which the nation is always paying but which it never realises, which Sir James Paget drew attention to many years ago at the first Health Exhibition in this city, the cost to the nation of preventable disease. And that cost, which means commercial inefficiency, is very largely due to alcohol. I wish now to show to this meeting, from the medical point of view, that for all this great cost, all this great expenditure, there is no profitable return. I am not speaking, of course, of those occasions on which a man, owing to a degraded custom, takes drink when he does business—everyone condemns that; but I want to speak to you of the occasions on which, as I have said just now, a man says, 'I take a little with my meals.' I want to point out to you that from the so called dietetic use of alcohol there is no profit. If we take alcohol into the stomach, a small quantity—and I shall speak to day of small quantities of alcohol, this quantity—20 grammes of absolute alcohol—and I shall have presently to refer to scientific experiments the whole bearing of which depends upon this amount of alcohol that we are going to [illegible] We often hear it [illegible] loes it do? In [illegible] stomach. In the second place, its immediate effect is a stimulant and irritative effect upon the mucous membrane of the stomach, and therefore it causes a little more secretion of gastric juice even during the short time it is in the stomach. But it has another effect, which is the ordinary effect of alcohol upon all fermentative processes, that is to say, it retards digestion. If you balance these two things together where is the profit? There is no profit as the net result of the effect of alcohol in the stomach. After the alcohol has left the stomach it is passed into the blood and carried to the nervous system and it is carried all over the body. While it is circulating in the body is there any profit from its action on all our tissues? It has been suggested, and again and again repeated, that alcohol is a food. What is meant by that? That when the alcohol is circulating all over the body it is oxidised in the body, it is utilised in the body, or some of it, a small portion of it, some people say more, others less. But take it that a small part is oxidised in the body. If it is oxidised in the body it should contribute to the temperature of the body—it should warm it. But all the temperature observations in connexion with alcohol show that the temperature of the body in the net result is lowered, so that even if this oxidation does occur in the body there is no profit from the point of view of temperature. And I may say in passing that the reason why the temperature of the body is lowered and not raised is that what might have been a beneficial effect is negatived by the selective action which alcohol has upon the nervous system. All drugs have a selective action on different organs of the body—that is to say, they pick out the tissue they can attack. Alcohol picks out the nervous system. And when it gets to the nervous system we recognise at once scientifically that alcohol, like chloroform and like ether and like all substances of that kind, has apparently a two-fold action. In reality it has a paralysing action throughout. But the first action that it appears to have is what we call in the case of chloroform the stage of excitation. It is a good word, because it does not convey an idea that the excitation is any good to the individual, therefore why not use it for alcohol? We will call it the excitation stage. Now, during this excitation stage people say 'I feel better, I can talk more.' Whether they talk better is another question, but they say, 'I am more sociable,' and so on. Well, now, let us put aside ordinary impressions of that sort and let us submit the question to the rigid test of experiment. When you come down to actual experiment you find that the sense of well-being which the person experiences is in itself a delusion, that so far from thinking quickly he is really thinking more slowly, so far from calculating better he is calculating worse, and so on, at the very time when he has this sense of elation and exaltation. And what is true of the effect of alcohol on the thinking part of the brain is equally true of that part of the brain which governs the finer movements of our hands and other fine movements. And when a person thinks he is executing a movement more accurately and with less tremor

action the work of the inspector would be much facilitated." But the special report relative to housing furnishes several instances of the difficulty of enforcing the nuisance sections of the Public Health Act in certain poor rural districts. At times the houses are in bad repair, the thatching being defective, the windows dilapidated, and the floors damp and uneven. For this accommodation the tenants pay 2*s.* 6*d.* per week and there are no other better cottages to which they can go save by paying a rent perhaps double that which they now pay. Moreover, if the tenants complain the landlord may take an early opportunity of getting rid of them. Instances of this nature are familiar to every medical officer of health and the only remedy, and this, we fear, is in practice but a partial one, is to insist upon systematic inspection of the houses of the poor in order that the occupiers may be relieved of the onus of complaining themselves. But generally the result of the survey to which Dr. Thresh refers was to show the necessity for more cottages at a low rental and with three bedrooms. For instance, at one of the villages it was stated that several engaged couples were being prevented from marriage owing to the scarcity of cottage accommodation. Dr. Thresh recommends [illegible] endeavour to erect houses in c[illegible] he thinks that it is quite impr[illegible] will cover the annual instalments of capital and interest. He does not, however, regard it as equitable that the rent should entirely cover these payments as, were it to do so, the tenant would, he urges, "be paying for property which would ultimately become the property of the parish or of your council." Assuming, he continues, "that each cottage left a burden of £2 per annum to be paid from the rates 50 such cottages would only increase the rates by £100 per annum and for £1000 per annum we could provide no less than 500 cottages" and, he adds, that he would rather see this sum spent annually in providing cottages than in supporting an isolation hospital. A point which is not referred to in the report before us but which is obviously one of economic importance is, What would be the value of the cottages in question when, as is anticipated by Dr. Thresh, they would become the property of the council? The answer to this depends upon two things—the character of the cottages and the time allowed for the repayment of the money borrowed to defray the cost of erection. Dr. Thresh refers to one interesting outcome of a threat on the part of the district council to put in force the Housing of the Working Classes Act in Ingatestone and Fryerning, where formerly there was great difficulty in obtaining housing accommodation. After the inquiries which took place in the village land was sold for building purposes and many cottages were erected. This is a very instructive case and we should like to see the experiment tried in several places where no cottages can be procured and no land can be obtained for building purposes. There are numerous places of this description within a short distance of the metropolis. Turning to the subject of water-supply we are glad to learn that in the case of new houses erected in this district no water certificates are given under the Public Health (Water) Act unless the wells are properly constructed, and leaflets setting forth the proper means are sent to the builders. This is a measure which should do much good and it might with profit be generally adopted throughout the country. It is extremely rare to find properly constructed wells and for some reason or other few well-sinkers appear to have any idea of well construction beyond that necessary to procure water of some nature. Attention is also being paid in the Chelmsford rural district to the important subject of the water-supply of dairies and cowsheds and some of the samples analysed during 1904 were found to be very impure. It is, however, refreshing to read that one of the cowkeepers sold his cows when he learned that the water-supply was polluted. In our own view there is no more pressing need at the present day than the improvement of the conditions under which the milk supplied to the public is procured and stored. If the public could be shown some of these conditions they would themselves agitate for reform.

Maldon Rural District.—Six cottages are [illegible] in one of the villages in this district under the [illegible] the Working Classes Act. Each house has [illegible] and the cost per cottage is estimated [illegible]

which an ordinary agricultural labourer with a family—even a small one—could afford. Many of the existing cottages in this district have, it is stated, been built on damp sites without any damp-proof courses and few have any paved area behind—an instructive reminiscence of the days when no by-laws were enforced.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8513 births and 5145 deaths were registered during the week ending March 11th. The annual rate of mortality in these towns, which had been 17·3, 15·7, and 17·1 per 1000 in the three preceding weeks, further rose to 17·2 per 1000 last week. In London the death-rate was 17·2 per 1000, which was also the average rate in the 75 other large towns. The lowest death-rates in these towns were 7·5 in Wallasey, 8·1 in Birkenhead, 9·3 in Hornsey and in East Ham, 9·6 in Northampton, 10·5 in Leyton, and 11 3 in Rotherham; the highest rates were 23·2 in Portsmouth, 23·4 in Hanley and in Nottingham, 23·5 in Reading, 24·9 in Middlesbrough, 27·7 in Wigan, and 28·9 in Merthyr Tydfil. The 5145 deaths in these towns last week included 471 which were referred to the principal infectious diseases, against 410, 365, and 486 in the three preceding weeks; of these 471 deaths, 178 resulted from measles, 132 from whooping-cough, 58 from diphtheria, 44 from diarrhœa, 37 from scarlet fever, and 22 from "fever" (principally enteric), but none from small-pox. No death from any of these diseases was registered last week in Brighton, Aston Manor, Stockport, Bury, South Shields, Tynemouth, or Newport (Mon.); [illegible] Nottingham, Wigan, Bolton, West Hartlepool, and Merthyr Tydfil; from scarlet fever in Handsworth (Staffs.); from diphtheria in Barrow-in-Furness; from whooping-cough in Willesden, Tottenham, Hastings, Hanley, Smethwick, and Rhondda; and from diarrhœa in Devonport and Hanley. The mortality from "fever" showed no marked excess in any of the 76 towns, and no death from small-pox was recorded during the week. The Metropolitan Asylums Hospitals contained 16 small-pox patients at the end of last week, against eight, 15, and 15 at the end of the three preceding weeks; three new cases were admitted during the week, against three, seven, and four in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2017, 1987, and 2002 at the end of the three preceding weeks, had further risen to 2036 at the end of last week; 303 new cases were admitted during the week, against 241, 224, and 290 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 378, 335, and 353 in the three preceding weeks, further increased to 361 last week, but were 53 below the number in the corresponding period of last year. The causes of 59, or 1·1 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Salford, Leeds, and in 45 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, Warrington, Blackburn, Bradford, Sheffield, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·9, 18·3, and 17·4 per 1000 in the three preceding weeks, rose again to 18·6 per 1000 during the week ending March 11th, and was 1·4 per 1000 in excess of the mean rate during the same period [illegible] 76 large English towns. The rates in the eight [illegible] towns ranged from 14·4 in Edin- [illegible] Glasgow to 23·8 in Greenock and [illegible] 625 deaths in these towns included 31 [illegible] to whooping-cough, 17 to diarrhœa, [illegible] diphtheria, one to scarlet fever, and [illegible] 58 deaths resulted from these [illegible] last week, against 52, 63, and

60 in the three preceding weeks. These 58 deaths were equal to an annual rate of 1·7 per 1000, which was slightly above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 27 in each of the two preceding weeks, increased last week to 31, of which 22 occurred in Glasgow, two in Edinburgh, two in Greenock, and two in Perth. The fatal cases of diarrhœa, which had been 13, 13, and 16 in the three preceding weeks, further rose to 17 last week, and included ten in Glasgow, three in Edinburgh, and two in Aberdeen. The deaths from measles, which had been seven and eight in the two preceding weeks, declined again last week to six, all of which were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 119, 116, and 114 in the three preceding weeks, rose again last week to 153, but were slightly below the number in the corresponding period of last year. The causes of 19, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·5, 25·5, and 30·7 per 1000 in the three preceding weeks, declined again to 25·2 per 1000 during the week ending March 11th During the past four weeks the death-rate has averaged 26·2 per 1000, the rates during the same period being 16·8 in London and 15·4 in Edinburgh. The 183 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 40 from the number in the preceding week and included two which were referred to the principal infectious diseases, against eight, five, and eight in the three preceding weeks; of these, one resulted from measles and one from "fever." These two deaths were equal to an annual rate of 0·3 per 1000, the death-rates last week from the principal infectious diseases being 1·6 in London and 0·8 in Edinburgh. The 183 deaths in Dublin last week included 37 among children under one year of age and 55 among persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a marked decline from the respective numbers recorded in the preceding week. Three inquest cases and two deaths from violence were registered; and 65, or more than a third, of the deaths occurred in public institutions. The causes of 18, or more than 5 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon William Robert Minchin Young has been placed on the Retired List at his own request (dated March 1st, 1905).

The following appointments are notified:—Surgeons: C. J. Boucher to the *Fire Queen*, for disposal; A. F. Fleming to the *Vivid*, for disposal; C. B. Fairbank to the *President*, for three months' hospital study; and J. Verdon to the *Vernon*.

Royal Army Medical Corps.

Major C. W. R. Healey and Major J. H. Daly are posted to Dublin and Queenstown respectively. Lieutenant-Colonel S. Westcott, C.M.G., is appointed Medical Inspector of Recruits to the Northern Command, at York, and Lieutenant-Colonel A. F. Russell, C.M.G., to the Eastern Command, at London. Surgeon-General W. Donovan, C.B., left England on March 4th for South Africa to take up his duties as Principal Medical Officer on the Staff of Lieutenant-General Sir Henry Hildyard at Pretoria. Lieutenant-Colonel H. O. Trevor is appointed Medical Inspector of Recruits in the Aldershot Army Corps. Colonel J. F. Routh, who has been serving on the strength of the Aldershot Command, has left England for India to take over administrative charge of a district on promotion. Colonel J. Magill, C.B., has left England for Egypt to take up the duties of Principal Medical Officer of the army of occupation, on appointment, in succession to Colonel W. A. May, C.B.

Lieutenant-Colonel G. F. A. Smythe retires on retired pay (dated March 11th, 1905). Major F. J. W. Porter, D.S.O., from the Seconded List, to be Major (dated March 1st, 1905). Lieutenant R. L. V. Foster is seconded for service with the Egyptian Army (dated Jan. 17th, 1905). Major R. H. Penton, D.S.O., from the Seconded List, to be Major (dated March 1st, 1905).

Army Medical Reserve of Officers.

Surgeon-Major A. A. Watson to be Surgeon-Lieutenant-Colonel (dated Feb. 28th, 1905).

A Russian Appreciation of Japanese Medicine.

At a sitting of the Vladivostock Medical Society on Jan. 20th last Dr. N. V. Kiriloff and Dr. Rontchevski spoke very highly of Japanese medicine and hygiene. The former rapidly traced the meteoric emancipation of Japan (where even in 1876 there were still 30,000 Chinese medical men) from Chinese medical tutelage up to 1901 when no trace of Chinese medicine, except in museums or in a few proprietary articles, could be found over the whole land. In addition to the two existing Japanese universities there are eight medical schools the students of which, though not equal in education to those from the universities, are in no way inferior to the average European medical man. "It must be recognised," he said, "that the sanitary aspect of medicine in Japan is not the best, although perhaps in respect to ordinary life nowhere do we meet with such cleanliness. Quarantine prevails in all Japanese ports." The *Vladivostok Listok* adds that Dr. Rontchevski confirmed the statements as to the efficiency of Japanese surgery and defective sanitation in the hospitals.

Army Recruiting for 1904.

The annual report on army and militia recruiting has just been issued and in existing circumstances will no doubt be closely scrutinised. It shows that of the numbers submitted to medical inspection 34·39 per cent. were rejected for various ailments and want of physical development. The report for the year ended Sept. 30th last. During the 12 months the number of recruits who joined the regular army, excluding Colonial corps, amounted to 41,279, and for the militia 35,264. The number of men medically inspected amounted to 71,699. In addition 20,075 who offered themselves were rejected by the recruiters or recruiting officers on physical grounds. The regulation that all recruits shall produce characters before being accepted for the regular army or militia has had satisfactory results. The question of defective teeth among recruits is stated to be a matter which becomes of greater importance every year. While the recruiting for the Foot Guards, although showing a slight increase, has been unsatisfactory that for the infantry of the line has been satisfactory, but this is probably largely attributable to the fact that the other arms of the service, owing to their surplus, were closed to recruiting.

The Army Estimates.

An explanatory memorandum of the Secretary of State for War has just been issued with the army estimates for the coming financial year. It will be closely examined by those who do not altogether share Mr. Arnold-Forster's enthusiasm regarding his new scheme.

The War in the Far East.

There is no need to dwell here upon the recent events of this terrible war; all our readers have been fully informed of them by official statements from both belligerents. The pursuit of the routed Russians, which threatens to break up what was recently the vast army in Manchuria into disorganised and scattered fragments, has been relentlessly followed up by the Japanese and the sum-total of military disaster is now unparalleled in history. Nor has an end yet come, but the imagination, dismayed at the extent of the losses and at the terrible misery and sufferings entailed on the sick and wounded in such circumstances, naturally shrinks from any attempt to forecast further horrors. It prefers to dwell upon the hope and the belief that the aim and the object of war being the disablement of the enemy the more speedily and completely this can be attained the sooner will peace be secured. Although it does not come within the purview of the medical journalist to deal with military history of an epoch-making kind the fact must be recognised that the Japanese strategical plans have been admirably conceived and wonderfully executed.

A Harbin telegram states that the greater number of the surgeons and a large portion of the Red Cross material have remained at Mukden. The sanitary services are said to be completely disorganised. Chloroform and antiseptics are lacking. The sick are piled up on uncovered trucks and the mortality is frightful. All civilian medical men are being requisitioned. The state of confusion is indescribable and it is the same at Tieling.

The St. Petersburg correspondent of the *Petit Journal* says that Harbin has been turned into a vast hospital. "Numerous trains," he adds, "are arriving laden with wounded, mostly half frozen."

The Central Committee of the German Red Cross Society has advised the executive that in view of the war in Africa the committee is regretfully compelled to economise its expenditure and that as much money is required for Germany's needs the German Red Cross Society will be obliged either to withdraw its hospital from Kharbin in June or to ask the Russian Red Cross Society to bear a portion of the cost of its maintenance. The reply received is that everything possible would be done to meet the wishes of the German Committee.

Correspondence.

"Audi alteram partem."

THE MEDICAL MAN AS EXPERT WITNESS.

To the Editors of THE LANCET.

SIRS,—Dr. W. B. Ransom's address to the Nottingham Medico-Chirurgical Society, published in THE LANCET of March 4th, p. 591, is very interesting and instructive but the only remedy I can see available is in what he says in conclusion—namely: "The system of Crown referees was intended to avoid this state of things but for some mysterious reason judges have ignored their existence." These judges are lawyers and I suppose they think they can assess the medical evidence better than a medical man or a lay person. Lawyers are always great on the "law of evidence" and we find as much divergence of opinion amongst them as we do amongst medical men. Even the highest judges in the land differ amongst themselves in the interpretation of the law—laws which have been drawn up by lawyers themselves—so that I do not think there is any more "temperament"—if this is the word—amongst medical men than we find amongst barristers and solicitors. It is sometimes said we are all more or less mad because of our peculiarities or idiosyncrasies, or I suppose we may now consider ourselves more or less akin to Ananias and some as related to Thomas called Didymus.

It would, however, be well both for the masters and also the workmen under the Workmen's Compensation Act if the medical referee could be called in early in every case of dispute and act as arbitrator between the medical men on both sides. [illegible] a medical man to look after their intere[illegible] have the same privilege? [illegible] the workman just as mu[illegible] if a medical arbitrator having the confidence of both could act as assessor after hearing the evidence on both sides, and making the examination himself, much would be gained and we should hear little of the conflict of evidence or of the "rinderpest" cases. In many of these cases sufficient note is not taken of the history of the case and therefore conclusions are arrived at which are not always justified.

The medical expert witness can only give his *opinion* after he has inquired into all the circumstances, he cannot speak as to facts. If a man's life is shortened by one minute through an illegal act of someone then according to law the person guilty of the act is guilty of manslaughter. Some judges have held this to apply to the workmen's compensation cases and hence when an injury has been received by a workman suffering from organic disease it is not difficult to conclude that the injury has accelerated death.

There are, however, many cases which are not necessarily fatal and in these scrupulous care should be taken with the case of injury. One remarkable case out of many occurs to me just now and this case, if it had been decided by the judge against the applicant, might have cast serious reflection on the medical attendant. The case was this. A man, under 40 years of age, received a fall of dirt from the roof on his right leg. He was able to hobble home and his wife went for the pit surgeon; he saw the case within two hours and within five of the man receiving the injury. He continued to attend the man for some weeks. The skin broke down and ulcers appeared. There was no doubt about these ulcers being specific and the man had to admit having had syphilis some years before. After a time the employers' insurance company refused to pay owing to the report of their medical officer saying that these ulcers were entirely due to syphilis and not to injury, being broken-down gummata. Although the pit surgeon could testify to the injury there was also other evidence of an accident, yet the surgeon held he was not suffering from the effects of the accident. No doubt in a healthy man this would have been so and there would have been no case for prolonged compensation. The judge, however, held that (1) he had received an accident; (2) he had not recovered from the effects of the accident; and (3) although he might be suffering from specific disease he was entitled to his compensation.

Having occasionally to appear in such cases I could if it were necessary give numerous similar instances. I appeared in one case before a learned judge who had as a barrister had cases of "railway shock." I believe he had experienced a railway shock himself. My case was that of a collier who had a severe injury and a fracture of his leg at the junction of the upper with the middle third. He had been off work 15 months, had firm union, and was getting fat from idleness and beer. I was sure he could follow labouring work. When, however, the surgeon was cross-examined and asked really what was the matter with the man he said he was suffering from *shock;* this, of course, worked the oracle and I got a cross-examination from the judge himself, when I stated that a collier who had a broken leg 15 months ago could not be still suffering from shock. My definition of "shock" and its effects was too feeble for the judge who kindly informed me that Charles Dickens, who had been in a railway accident 25 years before his death, died from the effects of the shock. Well, this was too much for me; the fear of contempt of court kept my mouth closed but my thoughts told me that Charles Dickens must never have received his compensation from the railway company. Apologising for the length of this communication, ..."

THE CLASSIFICATION OF THE INSANITIES.

To the Editors of THE LANCET.

SIRS,—I can pretend to no more than a languishing interest in the subject of the classification of the insanities, believing that further disputation of this matter is largely labour lost and that our energies can now be far better employed in the investigation of the diseases in question. But I will ask permission to criticise a few points raised in the annotation in THE LANCET of Feb. 18th, p. 445, entitled "Kinds of Insanity," which deals with an article with the same title by Dr. C. A. Mercier in the *Journal of Mental Science* for January last. Dr. Mercier says: "Puerperal insanity is acute insanity occurring within an uncertain time of childbirth, and if the antecedent of childbirth is unknown or disregarded there is nothing whatever in the clinical picture of the disease that is different from other cases of acute insanity that have no connexion with the puerperium." In his "Text-book of Insanity" (1902) Dr. Mercier writes: "Puerperal insanity is always an acute insanity ...... in addition to the description that has already been given of acute insanity there are certain characters special to the puerperal variety." He then refers to the impulsive violence (also seen in acute insanity) which in the puerperal form is usually directed against the infant; also to the fact that there is often a septic element in the case. Dr. Mercier, in his article to which your annotation refers, says that the insanity of pregnancy has a much better right to be considered a disease than puerperal insanity, since "the fact of the pregnancy is a continuing feature in the clinical picture, a feature which at once marks off the case from all other ca[illegible] of insanity." To my mind the continuing feature of pregnancy in the one case has, to say the least, no greater demarcating significance than the association with the puerperium in the other. For the association with the puerperium connotes *infection* and I believe that is the important point to have in mind. Dr. Mercier says in his book referred to, "Often, but by no means always, there is a septic element in the case." This is a somewhat vague statement. He produces no figures, nor does he show that he has investigated the point with such means of determining the question of infection as are at present at command. It is not necessary that the lochia should be offensive and the uterus tender (two points in evidence of infection to which he alludes) in order that there should be septicæmia. The pathological problem requires finer and more difficult methods of investigation than those above implied in order to its solution. Even in 1892 we find in Griesinger's "Pathologie und Therapie der Psychischen Krankheiten" (Levinstein-Schlegel's enlarged edition) these words, "Puerperal psychoses always coincide with an infection," and according to Hansen, quoted in this work, 42 cases out of 49 of puerperal psychoses gave evidence of puerperal infection. Campbell Clark (quoted by Griesinger), investigating 40 cases, says that in all the cause for the psychosis was blood poisoning from a peripheral lesion. And by puerperal insanity he means those psychoses which are connected with puerperal infection. I believe that with more abundant and skilled bacteriological and pathological research the nexus between the two conditions will be more fairly established. I might add here that cases of puerperal insanity have been treated with antistreptococcic serum on the assumption of septicæmia, and I can at present remember such an instance reported by Mongeri from, I think, the Italian Hospital in Constantinople, in the *Zeitschrift fur Psychiatrie*, where gratifying results were obtained. I am at present treating a case similarly myself.

Of course, if we were merely to take the mental symptoms of puerperal insanity it might be said that there was nothing whatever to distinguish the case from other cases of insanity, though I find Savage states that "there are still some symptoms commoner here than in other cases of mania: sleeplessness, apprehension, dislikes of relatives, erotic tendencies, mistakes of identity, and hallucinations of smell and taste." But Dr. Mercier's observation is made about the clinical picture *of the disease* and the disease, as everyone knows, has *par excellence* (with paralytic dementia and acute delirious mania) an important somatic side. There is commonly fever with the usual symptoms of that state, often very grave ones. In deciding whether puerperal insanity has a right to be considered a disease we have to look at the whole clinical picture. I hold it to be important that in the puerperal psychoses the great probability of septicæmia should be well in view and I should much prefer to retain the present term "puerperal insanity" (or preferably the term "psychoses associated with puerperal infection") rather than classify the condition under two tables, or two columns of one table, the one stating the fact of the puerperium and the other that of the insanity. The preferable designation, as I regard it, and which I give above, appears to me as reasonable and legitimate and practically useful as the expressions "rheumatic iritis" and "gonorrhœal arthritis."

To revert once more to the distinction drawn by Dr. Mercier as to the respective claims of puerperal insanity and the insanity of pregnancy to the title of a disease, it appears to me that, *mutatis mutandis*, the description of puerperal insanity which I have at the outset of these remarks quoted from the article is equally true of the insanity of pregnancy, and Dr. Mercier himself on the same page as that on which the quotation appears says: "There is nothing in the insanity of a pregnant woman except the pregnancy which differentiates the case from other cases of acute insanity." Yet whilst puerperal insanity is excluded from the list he gives of varieties of insanity that have any claim to the title of distinct diseases, insanity in pregnant women is admitted; only, however, "some cases" thereof. But there is nothing in what went before to prepare the reader for this qualified form of admission. Notwithstanding the above we find on reference to Dr. Mercier's book that amongst the "Varieties of Insanity" (subdivision "Insanities of Reproduction") both the conditions referred to appear.

Passing next to the claims of senile insanity to be considered a distinct disease "in virtue of the uniform and specific clinical picture that it presents," Dr. Mercier admits that he had some doubt, but this, it would seem, was dissipated on reference to Clouston's account of the malady, where that author confesses himself astonished at the immense variety of symptoms present in different cases. "This dictum," says Dr. Mercier, "at once abolishes the right of senile insanity to a distinct place in nosology." On a parity of reasoning should not hysteria, and perhaps influenza and typhoid fever, be excluded from our nosology? And since Dr. Mercier finds that senile insanity presents a "uniform and specific clinical picture" why should he, in deference to a dictum, exclude it from his category of distinct diseases, the criterion for admission to which, he tells us, is the "distinctness of the clinical picture presented"? If questions of nosology are to be determined or influenced by chance reference to text-books (I should judge Dr. Mercier to be one of the last persons so to determine), well and good. I pick up that excellent manual, Weygandt's "Psychiatrie," where, under "Rückbildungsirresein," I find a full and orderly description of senile insanity. I find an attenuated description (under "Varieties of Insanity," however) in Dr. Mercier's own book. I agree with Weygandt that there are usually in so-called senile insanity (the prominent feature of which state I take to be dementia but various mental states may be superimposed) symptoms which unmistakeably recall the psychology of the senium. And from the point of view of pathological anatomy (which I cannot find that Dr. Mercier in his book considers at all) it has been shown by competent observers, such as Alzheimer and Binswanger, that the alterations of the blood-vessels and their surrounding tissues are particularly noteworthy in senile insanity. I am further of opinion that as regards distribution of the lepto-meningeal changes, degree and extent of brain atrophy, extent and nature of cell changes, the post-mortem appearances in senile insanity are especially noteworthy. These various changes make up, I consider, a fairly characteristic pathological picture. Taking the complex of mental symptoms (and not picking out for criticism this or that feature, such as mania or a delusional state) and the pathological findings I consider there is a very fair case for placing senile insanity amongst the distinct diseases; a better case, in my opinion, than there is for insanity of pregnancy, and as good a case as there is for insanity of the climacteric, both of which are regarded by Dr. Mercier as having claim to be so called.

Dr. Mercier states, according to your annotation, that cases of insanity associated with bodily diseases, whether the latter be regarded as a cause or not, in no case present a clinical picture of sufficient distinctness to entitle them to separate rank as diseases and he excludes such from his list. But later he admits that the insanity of myxœdema is entitled to separate consideration as a specific disease and in his book he describes under "Insanity of Bodily Disease" the insanity of myxœdema, just like other authors do. Even for the purpose of collecting statistics I should prefer to collect cases under the heading "Myxœdematous Insanity" rather than under two headings in which the myxœdema is noted in one column and the insanity in another, as appears to be done in Table IV. of Dr. Mercier's article on the statistical tables in the October number of the *Journal of Mental Science*.

Your annotation states that Dr. Mercier would admit the claims of hebephrenia and katatonia to separate rank as diseases, but he says, on the contrary, that their individuality is destroyed for purposes of classification by the fact that they shade off by insensible degrees into the mass of insanity, and he does not mention them amongst his varieties of insanity with claims to the title of distinct diseases. The peculiar motor symptoms constitute the specific feature of the katatonic form of dementia præcox, whereas stupor is present, it is stated by those who classify this disorder, in not quite half the cases. If, as Dr. Mercier says, a specific clinical picture is essential to our notions of disease, I think it may well be doubted if various conditions recognised in the domain of general medicine have any more claim to the title than katatonia. Since the days of Kahlbaum and his school katatonia has been classed as a distinct variety of disorder by a large number of alienists. Whilst not disposed to class it thus myself I think it has as much claim to be so treated as certain of the varieties of insanity the claims of which are recognised in the article to which your annotation refers.

I am, Sirs, yours faithfully,
E. GOODALL.

Carmarthen.

THE CARBON FACTOR IN THE GENESIS OF GOUT.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 11th (p. 348) Dr. D. F. Shearer contributed an article entitled "Carbonic Acid as a Factor in the Genesis of the Gouty State." This article is noteworthy in that it directs attention—for the first time, so far as I know—to a retardation of carbonaceous excretion as the fundamental factor in gout. The writer argues that in the gouty the intake and absorption of carbonaceous material are excessive as regards the amount of physical exercise; that consequently the arterial blood is flooded with carbonic acid; that this excess of carbonic acid is responsible for the retention in the blood of uric acid which is known to occur in gout; and that the salutary influence of physical exercise in the gouty depends upon the increased exhalation of carbonic acid from the blood. A weak point in this hypothesis is that exercise increases, not only the exhalation, but the production, of carbonic acid.

Further than this, the argument rests upon the assumption—widespread but premature in my opinion—that carbonaceous material absorbed from the alimentary canal is of necessity katabolised or anabolised. Normally the blood is relieved of its carbonaceous material mainly by the capacities of the nitrogenous tissues for katabolism and anabolism; but we have no warrant for assuming that these capacities are invariably adequate for the task. Indeed, it seems a larger assumption to postulate an invariable adequacy than an occasional inadequacy.

Now an inadequacy of carbonaceous metabolism, even though slight, would lead to an accumulation of carbonaceous material of some kind in the blood. And if this be granted a large number of observations (experimental and others) could be adduced to show that such an accumulation leads to deficient renal excretion of uric acid. The result would be the progressively increasing uricæmia which is known to antecede the paroxysm of articular gout. Such would eventually involve extravascular deposition of a portion of the uratic load; and should this occur, as commonly happens, in some structure such as a joint which is capable of responding by acute inflammation to the irritation of the urate then we should have a paroxysm of acute articular gout. On this view the mechanism and influence, not less than the causation, of [illegible] Acute arthritis involves pyrexia; [illegible] combustion and so disperses the [illegible] the dispersion of the carbonaceous accumulation releases the uric acid accumulation and permits of free renal elimination; through renal elimination the blood recovers its solvent power and reabsorbs the extravascular deposits of uric acid. Thus is established convalescence not only from the arthritis but also from the condition of depraved general health which so commonly antecedes the arthritis and which is concurrent with the double progressive accumulation referred to. As Mead long ago said, "Gout is the cure of gout."

I believe that a progressive carbonaceous accumulation is *a common humoral factor of disease* and leads under varying conditions to various paroxysmal affections (amongst them acute articular gout), most of which result in relief from the carbonaceous accumulation.

I am, Sirs, yours faithfully,
FRANCIS HART.

Feb. 27th, 1905.

OLD EPSOMIANS AND THE JUBILEE OF EPSOM COLLEGE.

To the Editors of THE LANCET.

SIRS,—May I through your columns make known to old Epsomians generally (a very large percentage of whom enter the medical profession) that the Epsomian Club, in conjunction with the present head master, Dr. Hart Smith-Pearse, are arranging to commemorate the jubilee year of the school (1905) by [illegible] a register of old boys and their various professio[illegible]her with a brief sketch of the hist[illegible] and other items of interest?

Some dozen or so of us have undertaken the task of collecting the necessary statistics and circulars have been sent to all those whose addresses we can find. There are many hundreds of old boys, especially those who joined the College in its earlier years, whom we cannot trace and therefore I venture to ask, through your columns, any old Epsomians who have not received any intimation and who know the addresses of any old school fellows, especially those who have not entered the medical profession, to be kind enough to send me a postcard so that we may get into communication with them.

I am, Sirs, yours faithfully,
PERCIVAL TURNER.

4, Adam street, Adelphi, London, W.C.,
March 13th, 1905.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

To the Editors of THE LANCET.

[illegible] authorised him to send a report to your columns. He now writes to me expressing his regret that the substitution of the word "two" for "three" should have occurred as a purely accidental error in transcribing. I desire to be associated with his regret.

I am, Sirs, yours faithfully,
ROBERT JONES,
Honorary General Secretary of the Medico-Psychological Association of Great Britain and Ireland.

March 14th, 1905.

SHIFTING DULNESS IN PLEURAL EFFUSION.

To the Editors of THE LANCET.

SIRS,—Mr. Rickman J. Godlee's paper on Shifting Dulness, which appeared in THE LANCET of Feb. 25th, p. 480, though written primarily from the surgical point of view, invites comment from a physician. Mr. Godlee implies, and in your leading article upon his paper in the issue of March 4th you definitely assert, that "it is generally taught that the dulness due to a pleuritic effusion or to an empyema shifts with position under the influence of gravity." I should not have thought this to be the case but, on the contrary, I should have supposed it to be now generally accepted that the level of dulness in simple pleural effusion, whether serous or purulent, did not readily shift with position. I certainly have taught this for many years and in my book on "Diseases of the Respiratory Organs," p. 659, I write as follows:—

> *Alteration of percussion lines with position.*—In cases of hydropneumothorax, i.e., where air and fluid are present together in the pleura, it is very easy to [illegible] place quickly as the patie[illegible] to the sitting posture; b[illegible] strate this change when [illegible] indeed does take place, b[illegible] tion is to be found in t[illegible] forms although the lung [illegible] its own elasticity, still t[illegible] plete in those portions of [illegible] the fluid, while the rest [illegible] held up, as it were, against the action of the fluid is to some extent [illegible] the lung will not float as readily or change its [illegible]

[illegible] does not shift in front or [illegible]o do so behind, for it is at [illegible] lapse of the lungs is most marked. If these facts are not yet generally recognised they have, at any rate, been long enough known, as the following quotation from Fagge[1] shows:

> A circumstance which has long attracted the attention of clinical physicians is that temporary changes of posture of the patient often fail to alter the position of the liquid within the chest so far as one can test by percussion.

The answers sometimes given by students in examination, if they may be taken as any indication of the views of their teachers, seem to justify the conclusion drawn by Mr. Godlee that the teaching on this point is in some quarters not by percussion remain the same both in the erect and recumbent position. No doubt this is in part due to the comparative flatness of the arch of the diaphragm in front, but it is chiefly the effect of the action of the abdominal muscles which in the erect position contract and thus support the weight of the liver and the heart and prevent them from falling. Where the abdominal muscles are greatly relaxed or very weak it is probable that these organs may fall in the erect position and the upper limit then descend.

---

[1] [illegible]es of Medicine, 1889, p. 916.

It is, as Mr. Godlee says, useless to percuss out the abdominal viscera when the patient is standing up, but I do not agree with the explanation which he gives—viz., that there is in the young and healthy adult not much gas in the small intestines and only a moderate amount in the stomach and large intestine. The true explanation is to be also found, I believe, in the contraction of the abdominal muscles, which is of itself sufficient to give an impaired or even a dull note. I remember an excellent illustration of this being given by an acrobat who exhibited himself in the theatre at St. Bartholomew's Hospital. He was able to dislocate most of his joints by muscular action and could wriggle through a hoop only just large enough to go over his head. He was able also to produce a phantom tumour in the abdomen as large as his head. Percussion over this was quite dull and the dulness was evidently due to contraction of the abdominal muscles. When the abdominal muscles are large and well nourished, as in the young healthy adult, their contraction in the erect position would rob abdominal percussion of any value. In overfed dyspeptic persons with pendulous belly and ill-nourished muscles the difficulties of percussion in the upright position though decreased by the want of tone in the muscles would be increased by the amount of fat in the abdominal walls. So that in any case abdominal percussion in the erect position would be misleading.

I am, Sirs, yours faithfully,

Wimpole-street, W., March 6th, 1905. SAMUEL WEST.

THE GOUTY DIATHESIS.

To the Editors of THE LANCET.

SIRS,—As it appears from Dr. S. A. Arany's letter published in THE LANCET of March 4th that he has misunderstood the aim of the experimental investigations recorded in my paper in your issue of Feb. 11th, and also my estimate of the significance of their results, perhaps you will kindly allow me to make these points clear. It is generally admitted that an excessive meat dietary is prejudicial to gouty individuals, the reason usually assigned being the large amount of uric-acid-forming bodies in this diet. As a result of a long series of laboratory investigations I was led to conclude that uric acid does not play the important etiological rôle in the production of gout that is commonly supposed and in this connexion it is of interest to note that this teaching of the laboratory is in harmony with the views expressed by some leading clinicians of wide experience in this disease. In a recent paper[1] I submitted a summary of the facts obtained in these investigations and I suggested that the present position of our knowledge of gout made it advisable to prosecute inquiry along the following lines: (1) to ascertain the effects of a special dietary—e.g., an excessive meat diet—on the economy; and (2) to test the validity of the view that there is an infective element in the disease. In pursuance of this inquiry I fed a number of fowls on a diet of meat and water. Fowls were selected as being subjects relatively prone to over-production of uric acid in the tissues. I later made a series of similar observations on rats, whose normal diet more closely resembles that of the human subject. In neither series was there any deposit of urate of soda; in both very striking changes were induced in the thyroid glands. Dr. Arany states that this result proves nothing regarding gout. I quite agree with him. My point is that the facts are most suggestive and it appears to me that they justify the suggestion that in people who persistently take an excessive amount of meat or whose forbears have over-indulged in this direction there may be present a condition of thyroid gland which is different from that of healthy individuals and, further, that this difference may have something to do with the gouty diathesis. Dr. Arany lays stress on the facts that gout is found in subjects who have never been large consumers of meat and may even be met with in patients who are practically abstainers from a meat diet. These may be regarded as well-established facts in the disease but I submit that a deeper insight into the significance of these facts may lead to their being correctly regarded as important evidence in favour of my theory. No definite statement on this point can be made until we ascertain the condition of the thyroid and the forms of its functional activity in the cases referred to by Dr. Arany.

Your correspondent states that in a series of almost 400 cases of gout he "did not observe in a single case any symptoms which could have related to changes in the thyroid gland." This statement implies two assumptions which call for comment. It presumes a precise knowledge of the functions of the thyroid gland and also a comprehensive grasp of the changes induced in the economy by a diminished secretion (hypothyroidism), excessive secretion (hyperthyroidism), and perverted secretion of the gland. With regard to the first assumption, I would point out that recent works (Jeandelize, Swale Vincent and Jolly, and others) have shown that our knowledge of the physiology of the gland is very incomplete. With regard to the second assumption, it is probably not too much to say that all clinicians who have devoted special attention to the subject of the thyroid gland in its clinical and therapeutic aspects are of opinion that a knowledge of the changes induced in the system by alterations in the character of the thyroid secretion still remains one of the most important desiderata in our medical knowledge. In these circumstances one is perhaps justified in hesitating to attach much scientific value to Dr. Arany's pronouncement on the results of his clinical experience regarding a relation between gout and the thyroid gland, and it may not be unreasonable to hope that a record of fresh and important facts, which show the possibility of such a relation, may lead clinicians who have shared his experience to extend the area of their observation, and closely to scrutinise the facts that lie within their purview, in order to obtain positive evidence for or against the existence of the suggested relation.

I am, Sirs, yours faithfully,

Edinburgh, March 6th, 1905. CHALMERS WATSON.

THE INTRUSION OF THE LAYMAN INTO MEDICAL PRACTICE.

To the Editors of THE LANCET.

SIRS,—May I be allowed to draw attention to some points raised by the letter in THE LANCET of March 4th from Messrs. Allen and Hanbury? The particular case mentioned can no doubt be dealt with by the gentleman whose letter called forth their reply but in the latter half of their letter Messrs. Allen and Hanbury write as if thereby they dispose of the whole question. I venture to think that there is more to be said. No one can blame Messrs. Allen and Hanbury for opening "a department of business" at the request of leading members of the medical profession. That they should carry it on—with a costly plant requiring constant expense to keep it up to date and an assistant paid we hope an adequate living wage, and all this at "an entirely insignificant profit"—seems worthy of commendation from all but shareholders. This "department of business" is described as an endeavour to assist the profession in "mere mechanical and subsidiary matters." It is admitted that it includes not only the taking of x ray negatives but also exposures for treatment. The assistant who does the work has no medical qualification. The necessity for medical training in the making, and especially in the interpretation, of x ray negatives is obvious enough to all who are conversant with the subject. The therapeutic use of x rays should certainly be in the hands of medical men who have given time and study to the subject. It is beside the mark to say "under the direction of the medical man," for unless himself well versed in the detail of the work he is entirely in the hands of the person to whom he intrusts it. As to the "presence of" the same, it would be interesting to know how often the medical man attends the numerous sittings necessary. Then as to the establishment of such a "department of business" by a commercial firm. Why should it be called for at all—even if conducted on the almost philanthropic lines of Messrs. Allen and Hanbury? It is open to the profession, as they kindly point out, to "take patients to professional brethren who practise radiography," "but several have told us that they object to do this." They might have said "many" object—it is a matter of common knowledge; but I have never heard an explanation from anyone whose opinion was valuable from the side of those who prefer to take their x ray work to non-medical people rather than to their "professional brethren who have made a study of the subject."

I am, Sirs, yours faithfully,
F. HARRISON LOW, M.B. Aberd.
Henrietta-street, W., March 7th, 1905.

IRRIGATION IN PERFORATED GASTRIC AND DUODENAL ULCERS.

To the Editors of THE LANCET.

SIRS,—In the recent correspondence upon duodenal ulcer marked difference of opinion has been expressed as to the advisability of irrigation in operations for ruptured ulcers. The same difference of opinion was evident in the discussion which followed a paper on 50 Consecutive Cases of Perforated Gastric and Duodenal Ulcer which I read before the Royal Medical and Chirurgical Society in November, 1903. Since that time I have carefully studied the question of irrigation in cases upon which I have operated personally or have seen others operate and I have come to the conclusion that irrigation is advisable in all cases of acute perforation, whether operated upon early or late, and for the following reasons. Firstly, the mortality has been lower in those cases treated by general irrigation at St. George's Hospital during the last two years than in those treated without irrigation. Mr. G. R. Turner has already referred to a series of 12 cases of ruptured gastric and duodenal ulcer with nine recoveries; in these cases thorough irrigation of the peritoneal cavity was a prominent feature in the treatment. Secondly, complications have been far less frequent in cases in which irrigation has been employed and this is a very trustworthy test of the extent to which the peritoneal cavity has been cleansed. Thus in three cases upon which I have operated recently three and a half, five, and seven hours respectively after perforation, and in which I flushed out the peritoneal cavity with some 10 to 20 pints of saline solution, convalescence was absolutely uninterrupted. Thirdly, I have not yet seen a case in which the abdomen was opened above the pubes without a large quantity of turbid fluid being found in the pelvis even in the earliest cases. It seems to me that the thorough removal of this fluid, which can only be effected by sponging and irrigation, must greatly assist in the patient's recovery. Further, this proceeding will lead to the formation of far fewer adhesions in the pelvic cavity—a matter of especial importance in females. In two instances I have met with severe dysmenorrhœa and sterility following directly upon perforation of a gastric ulcer in which no attempt was made to cleanse the pelvic peritoneum. In each case the pelvic organs were felt bimanually to be firmly matted together.

These facts appear to me to form a strong argument in favour of thorough irrigation in these cases.

I am, Sirs, yours faithfully,
Grosvenor-street, W., March 7th, 1905. T. CRISP ENGLISH.

CHLORÆTHOFORM.

To the Editors of THE LANCET.

SIRS,—It is not in our province to express any opinion of our own on a therapeutic or pharmacological question, but we may be permitted to point out that the statement that chloroform prepared from alcohol is superior as an anæsthetic to chloroform prepared from acetone is by no means generally accepted by medical authorities. Some eminent surgeons use regularly the chloroform prepared from acetone and a vast number of general practitioners find [illegible] have been told [illegible] ed chlor- æt[illegible] the pure ace[illegible] can be detected in the behaviour of a mixture containing 0·25 per cent. of ethyl chloride from that of pure chloroform, it seems highly improbable that a mixture containing only 0·05 per cent. can comport itself differently from pure chloroform. Yet 0·05 per cent. is all that is alleged to be present in chloroform prepared from alcohol. It may further be noted that Mr. H. Finnemore and Dr. J. Wade in their communication to the Chemical Society[1] do not describe how their chloroform was prepared or give evidence that chloroform formed from ethyl alcohol must necessarily contain ethyl chloride. In some samples of alcoholic chloroform we have not been able by the usual analytical methods to detect ethyl chlori[illegible] present at all, in ver[illegible] up to the present t[illegible] adduced to establish the views favoured by Mr. Finnemore and Dr. Wade.—We are, Sirs, yours faithfully,

Edinburgh, March 6th, 1905. J. F. MACFARLAN AND CO.

ANTHRAX AT NÜRNBERG.

(FROM A SPECIAL CORRESPONDENT.)

A VISIT to Nürnberg on the way through from Geneva to Berlin has given a good opportunity of studying on the spot the method of steam disinfection as a preventive against anthrax, on which Dr. T. M. Legge will be giving full information in the Milroy lectures this month. Nürnberg is a town of 285,000 inhabitants, including amongst others many brush and bristle factories. By far the largest concern in this line is the "Vereinigte Pinsel Fabriken," which has combined the chief brush factories, and in one of these is a complete steam disinfecting apparatus through which all the raw material used in this company's works is passed before undergoing any other treatment. The apparatus is to all intents and purposes a Washington-Lyons disinfector, built into a wall so as to divide the infected in-take room from the non-infected out-take room in our ordinary disinfecting installations. It is made by Rietschel and Henneberg of Berlin and Dresden. The disinfecting house is a small separate building, surrounded by air on all sides and fed by steam at a pressure of two atmospheres from the same boilers which supply steam for treatment of the material at a later stage at a pressure of eight atmospheres. The disinfecting house is well ventilated directly by doors and windows as well as by more elaborate inlets and outlets, the air entering by inlets near the floor being warmed by the radiators which maintain the general warmth of the two rooms. The door of the apparatus, which is eight feet high and fastened by eight strong screw bolts, is opened on its hinges and the cage is run out on wheels. The bundles of bristle are loaded on the transverse trays, which slide in one above the other, the material likely to afford resistance to the penetration of the steam being opened out, while some packets wrapped up in paper are slashed with a knife. In the midst of one of the lightest bundles is stowed away an *electric contact thermometer, in which the contact of* two halves of a sphere, one half fitting into the other, is prevented by an axial cylinder inside them composed of fusible metal which melts at 103° C. and then allows contact, notifying the fact by the ringing of a bell outside the apparatus. The caged bales are protected from moisture condensing out of the steam by a metal roof and between this metal roof to the cage and the outside metal of the disinfector the steam is eventually let in, being thus well distributed through the chamber. Two maximum thermometers are hung in the interior to record for trade purposes the highest temperature reached during the process. While the cage is wheeled out on metal runners a glimpse into the air-jacketed chamber shows its lower part occupied by horizontal radiators which warm up the chamber by dry heat so as to prevent condensation of moisture when the steam is admitted, for moisture and a high temperature are both alike injurious to the bristles. The cage, fully loaded, is now run in, the door is closed and bolted, and after any time from one to three hours, as may be convenient to the staff, steam, sent across from the boilers at a pressure of two atmospheres, is admitted to the disinfector. An outside manometer shows when the pressure inside reaches the limit of 0·15 atmospheres required by imperial regulations and the ringing of the bell records the fact that a temperature of 103° C. has been attained in the interior of the bundles inside. Not until both these records have been obtained, after a period varying between 17 and 27 minutes from the start, is the electric circuit broken by hand so as to stop the bell ringing, and the actual time is recorded in a book as the time at which disinfection began. A current of superheated steam is now flowing through the apparatus, guarded by a safety valve, and at the end of half an hour the time is again recorded in the book and the steam is turned off from the chamber and on again through the pipes which keep the chamber warm. The disinfected material is thus allowed to cool down gradually for from two to seven hours, while steam is replaced by warm air; and, finally, the further door is opened, the cage is run out into the non-disinfected room and unloaded in safety by the workmen who have cast off the washable overalls in which they loaded the infected material and washed their hands and faces in soap-and-water and disinfectant. The overalls are sterilised each time. This process is repeated with fresh material every morning; two workmen are sufficient for the work, and the average cost comes only to four marks per 100 kilos, about 2*s.* per hundredweight—a quite insignificant amount. Small factories in the city disinfect their material in the disinfectors erected by the city authorities to serve both this purpose and also that of disinfection in cases of other infectious diseases. Here the cost to the owner is five marks per 100 kilos. Full and detailed investigation by the Imperial Health Office in Berlin is said to have proved the complete efficacy of this procedure in killing even anthrax spores. The procedure has been in vogue in these factories owing in some degree to demands from the workmen, since the promulgation of rules to this effect by the city in 1895. It was not, however, till 1902 that the Imperial Government issued an order on the subject; and in this Imperial order only foreign material is subjected to disinfection.

---

[1] Journal of the Chemical Society, July, 1904.

But the proof of the pudding is in the eating, of the spore in the pathology. Have these regulations diminished the number of cases of anthrax? To determine this question it was necessary to consult the Statistical Bureau, which referred to annual reports for its tables of mortality, and the police-office which turned up a memorandum in MS. as to the cases notified. The results thus obtained are the following:—

—	Cases.		Deaths.	
	Men.	Women.	Men.	Women.
1888...	1	—	1	—
1889...	—	—	—	—
1890...	3	—	1	—
1891...	1	1	1	—
1892...	1	—	1	—
1893...	4	1	—	—
1894	4	1	1	—
City Regulations introduced.				
1895...	1	3	—	2
1896	3	2	1	1
1897...	1	1	1	1
1898...	12		—	—
1899				
1900...	?		—	—
1901...	?		—	1
Imperial Order issued.				
1902	?		—	—
1903...	?		—	—
1904...	?		1 ?	—

All cases are notifiable by all medical men diagnosing the condition, but unfortunately these notifications for the last seven years have simply been filed and never compiled, still less published, and the office will have very great trouble in sorting them out, which, however, the staff hope to be able to do as a result of to-day's visit, although it may mean a fortnight's work. It is incredible that in a town of such size and importance the wider value of notification should be absolutely squandered on an office file. But problems of public health are not dealt with on far-seeing lines in most continental towns of my acquaintance.

The police secretary was of the opinion that a certain number of cases had been notified during the past few years and the 12 cases in 1898–99 do not look as if the number had been decreased by disinfection. Moreover, he was inclined to believe that many cases had passed unnotified. It appears that in the early "nineties" only two medical men in the town interested themselves in the disease and many cases may have passed unnotified. Since then the disease is well recognised, even by workmen; but it is also well treated in an early stage by every practitioner and when a local pustule has been simply excised without any general symptoms or unfavourable circumstance the case will not improbably escape notification, especially seeing that the duty of notification is not so generally recognised on the continent as with us, even by many of the medical profession who openly plead the interests of the patient as opposed to those of the State. It is quite likely, therefore, that the total number of cases has not diminished since the introduction of steam disinfection. But there is no gainsaying the mortality figures, which show only one certain and one doubtful death during the last seven years. In addition to this may be added the statement of the director of the large factory already referred to that they have not had a single case of infection since the introduction of their steam apparatus and the general statement of the superintendent of the hospital, who till last year was also Stadt-arzt with many of the functions of a medical officer of health, that there had been no case notified or under treatment in the hospital in recent years.

THE EPIDEMIC OF SCARLET FEVER AT NORTHAMPTON.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Northampton, March, 1905.

THERE has been an epidemic of scarlet fever at Northampton which presents some peculiar features. The population of the town must now amount to a little over 90,000. This is equal to a very small fraction under five persons in each house and 26 inhabitants per acre. Thus, except it be in certain localities, the town cannot be said to suffer from overcrowding. Indeed, the death-rate is very low and in the last report published, which is for 1903, it is estimated that though the average death-rate for the previous ten years was 15·6 per 1000 the death-rate for 1903 was only 13·5 per 1000. At the same time it must be noted that the birth-rate did not exceed 24·4 per 1000. This is the lowest birth-rate on record. In 1893 the birth-rate was 30 per 1000; in 1895, 31·5 per 1000; and since then it has steadily decreased. The cause of this fall in the birth-rate is not to be ascribed to a decrease in the frequency of marriages; it is wholly due to a reduction in the fertility of marriage. In 1891 100 families produced on an average 26 children and ten years later the average was 22 children. Though such reduction in the birth-rate accounts in a measure for the low death-rate there has also been a reduction in the proportion of deaths of the infants born—namely, 137·2 deaths per 1000 infants under one year of age, and this is a low rate for Northampton. Thus, and taken altogether, it may be said that the vital statistics testify to satisfactory and to improving conditions. Nevertheless there has been an extraordinary prevalence of scarlet fever. The epidemic has slowly developed itself and has now entered upon its third year, though it is showing evident signs of abatement.

During the first quarter of 1903 there were 129 cases of scarlet fever notified, resulting in a case mortality of 2·3 per cent. During the second quarter the number of notifications —127—was almost the same but there were 5·5 per cent. of deaths, and in the third quarter 139 cases resulted in 4·3 per cent. of deaths. This is in all 395 cases for the first nine months of the year; and now the more serious development of the epidemic began, for there were 269 cases notified during the last quarter of the year. On the other hand, the proportionate mortality fell to 2·9 per cent. of the cases. Evidently matters were not likely to improve in 1904 and, indeed, there ensued a much more serious epidemic. But, and before dealing with this, it is instructive to look back for ten years so as to realise the hold which this disease has on Northampton. The only two years that can be compared with 1903 are 1897 and 1898, when there were 866 and 731 cases of scarlet fever notified. This was equal to an attack rate of 14·2 and 11·9 per 1000 of the population. In consequence of the increase of the number of inhabitants the attack rate for 1903 is only equal to 7·36 per 1000 These were the three worst years during the decade from 1894 to 1903 It is true that the attack rate was nearly as bad in 1894—namely, 7 03 per 1000 but in 1895 it amounted to only 4 4, in 1896 to 6 3 in 1899 to 5 5 in 1900 to only 1 5, in 1901 to 1 96 and in 1902 to 1 82

In 1904 there have been no less than 2224 notifications of scarlet fever or 24 3 cases per 1000 of the population It will be seen how very much this exceeds all previous records Fortunately the reduction in the proportion of deaths is as remarkable as the increase in the proportion of cases The deaths, which amounted to 4 7 per cent of the cases notified in 1897 and to 5 5 and 4 3 per cent of the cases notified so recently as the second and the third quarters of the year 1903 were only equal to 1 8 per cent of the cases notified in 1904 The argument that the proportionate mortality is less because the notifications are more rigorously enforced and more complete hardly applies in the present instance Within the last ten years or so there has been no particular alteration in this respect The practice of notifying such a disease as scarlet fever was fully established more than ten years ago and had become quite a habitual custom

The first great difficulty that arose as the fever spread was to find room for the isolation of so many patients In 1902 when only 161 cases of scarlet fever were notified, 73 2 per cent of the patients were removed to the isolation hospital In 1903 however when 662 cases were notified the proportion removed to the isolation hospital fell to 60 1 per cent Finally, in 1904 out of the 2224 cases notified only 746 patients could be taken in at the fever hospital This great discrepancy between the number of cases and the number of patients isolated raises *the question as to the rules or principle adopted in deciding* as to who should be allowed to remain at home and who should be taken to the isolation hospital The conditions governing such choice were laid down in 1903 and the following are [illegible] e the patient if [illegible] The proximity [illegible] finement it is well known, is most dangerous to the mother The patients are also removed when a part of their dwelling is used as a shop a workshop, or a domestic workshop Again if there [illegible] more necessary [illegible] he rooms are [illegible] patient from [illegible] n institutions such as a workhouse or barracks are at once removed Moreover the patient is taken to the fever hospital if the adults of *the family are engaged in trades likely to spread* the infection, such as laundry work tailoring, millinery the making of *underclothing*, &c Finally the children of charwomen and others are removed when the parent has to go out to work and therefore might convey the infection else [illegible]

[illegible] to t [illegible] school of the closing of schools It [illegible] ever, that the disease was not localised that it did not affect any one particular school To do any good by dealing with schools nearly every school would *have had to be closed* and some 8000 to 10 000 pupils sent home This was too serious an undertaking and as the disease was of an exceptionally mild form such rigour did not seem justifiable Of the cases recorded among school children it was noticed that the *proportion* was a little higher among those who attended the non provided schools when compared with those who attended the provided schools It would seem therefore, that the schools built by the old School Board are in a better sanitary condition or are more satisfactorily managed than those that were built by the various religious denominations The difference was very slight but very general Thus in October last out of 351 cases notified 89 4 per cent attended the provided and 90 per cent the non provided schools In November the proportion was 88 4 as against 86 3 per cent in favour of the provided schools

During the epidemic there were very many cases of so mild a character that some of them not only escaped the notice of the parents but in one or two cases even medical men in attendance did not feel themselves justified in sending a notification till the period of desquamation had been reached In other instances the desquamation was noticed at school and the pupils had been in regular attendance, no one being aware that there was anything serious the matter The probability *is that* this explains the widespread nature of the epidemic With more severe cases better care would have been taken to separate the sick from the healthy and there would have been less danger of direct infection But though such negligence may be excusable where the symptoms are very slight and obscure there were many other cases where culpable negligence occurred In a good many instances the patient though suffering unmistakeably from the fever was found lying in the living room with all the members of the family and visitors constantly going in and out The medical officer of health of Northampton Dr James Beatty seeing the immense difficulty of removing many hundred cases to the fever hospital suggested that arrangements might be made for isolation at home by boarding out the other children If houses could be *found where there were no children* the adult inhabitants might be willing to take in unaffected children from a house where a case of scarlet fever had occurred Of course the question of payment is the principal difficulty In many cases the parents would not be able to pay or at least to pay enough and it is questionable whether the sanitary authority has a legal right to employ public funds for such a purpose Then again one or more of the children thus taken in might fall ill and who in that case would pay for disinfecting and re decorating the house? This question of compensation for disturbance incurred for the protection of the public health is a phase of sanitation which has still to be dealt with When a case of infectious disease occurs the interest of the individual undoubtedly often runs counter to that of the general public To stop the business of a laundry of a milk dealer or of a *tailor is often disastrous to the individual* concerned and as there is no compensation forthcoming it is not surprising that concealment should be attempted On the other hand where there is no concealment the individual finds his business stopped his customers scared and finally he has to incur considerable expense in redecorating his home after it has been more or less devastated by the disinfectors All this trouble he endures mainly for the sake of the public, for the danger at least the immediate danger so far as it affects himself or his family has already been incurred It does seem especially when the persons involved are poor, that some *compensation should* be allowed Illness naturally entails loss and sacrifice but in some cases the isolation of the patient and the subsequent disinfection may result not in a mere temporary loss but in something like absolute ruin In such circumstances the temptation to conceal is very great and such temptation constitutes a public danger These remarks of course apply to any town but in Northampton they acquire extra force because the hospital accommodation is not sufficient for an epidemic producing more than 2000 cases in the course of 12 months When the patient can at once be removed to the hospital the interference with the business need not last longer than a few days But if there should not be room at the hospital then a laundry a tailoring establishment or any similar business might have to be stopped for several weeks and such interference might well result in the loss of custom *which had been acquired* only after years of patient attention and work Nor are such considerations so far as Northampton is concerned of a merely retrospective interest During the course of the present year there have *been* signs of abatement in the prevalence of scarlet fever but nevertheless the number of cases notified is still far in excess of the normal A few days ago no less than 280 cases had been notified since Jan 1st 1905 It is therefore probable that the figures for the first quarter of the current year will exceed 300 This is still a very high case rate Fortunately, the proportion of deaths remains very low

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Poisoned in a Sewer

ONE of those tragic occurrences often called accidents the result of incautious descent into a sewer took place on March 6th at Warrington At the inquest on the man who died the evidence showed the ignorance or folly so often seen in these cases and also the self sacrificing courage that is equally conspicuous in the rescuers. The first to go down the manhole was so affected that he came up at once. He then staggered and became unconscious but revived after a time. Evidently his escape was a narrow one. Two other men then went down. In a few minutes one of them fell unconscious. The other went to his help but was obliged to come to the surface and he, too, quickly became unconscious. Two other men then went down to the rescue but both were overcome. When Bretherton, one who had previously been down, had recovered he went down again to look for his mate and found him with the two who had gone into the sewer last lying at the bottom of the manhole. A crowd had gathered by this time and one of those assembled, James Stockton, for his name deserves mention, at once went down to render help but had in a short time to come up. However, he went down again, taking a rope which he tied round one of the men who was pulled up. Then he roped a second who was also safely drawn up. He then went down for the other man, Baxter, who was dead when brought up. It is interesting to note that when medical aid arrived some of the spectators were already using artificial respiration. The evidence seemed to show that there was a sudden rush of noxious fumes and the borough surveyor alleged that a firm in the town turned hydrochloric acid into the sewer on the morning of the accident. The verdict was "Death from suffocation caused by gas." There was no blame attached to the corporation or its servants. Great admiration of the conduct of Stockton was expressed and the coroner was asked to recommend him to the Royal Humane Society for reward. The men Baxter and Mitchell, the former of whom lost his life, were eulogised for their bravery in attempting a rescue. Such "accidents" as this just related ought to occur much less frequently than they do. The dangers of the sewers are known but no care is usually taken to ascertain if they are free from noxious gas. But this ought to be ascertained and if foul air is shown to be present it should be driven out before workmen are allowed to go down. The sudden rush of fumes from hydrochloric acid being discharged into sewers could not so easily be guarded against. But is there no better way of disposing of hydrochloric acid than pouring it into the sewers? Mere dilution with water at any rate would prevent fumes arising. The Warrington corporation was declared free from blame and there is nothing more to be said, but the Warrington corporation shares with other corporations the grave responsibility of seeing that those whom they employ run no unnecessary risk.

Human Life a Commercial Asset.

Perhaps the value of human life will come home to the multitude more easily when its money's worth is shown than when it is considered only from the moral and sentimental standpoint. Dr. W. E. Barker, the medical officer of Clitheroe, thinks that "human lives from the commercial standpoint are too valuable to England as a nation to be needlessly frittered away." That they are thus frittered away results, he considers, from the bulk of the populace being "completely ignorant of the most elementary laws of hygiene" and from the prevalence of "the most gross superstitions" as to the causation and treatment of many of the most prevalent diseases. Thousands of lives, he says, and as we all know, are lost annually "from one simple cause alone—ignorance as to the proper feeding of an infant." This is of course an oft-told tale but it should be repeated till the understanding of those who regulate the teaching in our elementary schools is impressed with the terrible results of the present unpractical system. Dr. Barker thinks the teaching of hygiene in elementary schools "would obviate this deplorable state of things." What a commentary this is on the system of education that has been dominant for 30 odd years. Children who will have to work for their living are crammed with the sort of book knowledge which is generally useless as an aid to earning their bread, while practical teaching has been almost ignored. May we hope for better things when people have ceased to quarrel over the 1902 Act?

"*Beautiful Oldham.*"

Æstheticism can flourish even in these northern regions, for the idea of beauty as something worth cultivating seems to have established itself in a town that, without much exaggeration, might be considered as rivalling, if not surpassing, any of those in the manufacturing districts in point of ugliness. But an effort is being made to brighten some of Oldham's dull places with trees and shrubs. School gardens have been instituted at a number of the elementary schools and the "Beautiful Oldham Society" is always on the look out for desolate spots of vacant land which, with the permission of the owner, are planted with shrubs. Some of the railway embankments have been treated in the same way and attempts have been made to brighten slum courts. One court had an insanitary ashpit in the centre which was removed and a little garden made in its place. The boys of the court take care of it and have great pride in their garden. Numerous other instances might be given, for the society is always active. Smoke, as we know too well, is one of the greatest difficulties met with by those who seek to render the grimy northern towns less ugly and more wholesome and the society is doing valuable work in directly and indirectly lessening the smoke nuisance. Of course, the society has been ridiculed, for the idea of beautifying Oldham appeared too absurd for imagination, but the movement has received the flattery of imitation, similar organisations having been founded in several Lancashire and Yorkshire towns and "inquiries have come from places so remote as Newcastle." Something may be hoped for in the increasing use of gas for heating purposes and still more, perhaps, from the use of electricity for the diminution of smoke, but there is still a good deal of prejudice and a clinging to old methods which has gradually to be overcome.

A Child Hero.

It has not been told us by those who have studied the life of the child at what age altruistic courage begins to show itself. The following case, reported in the *Manchester Guardian* of March 9th, seems deserving of notice. At the Blackburn police-court on March 8th the Mayor handed to James Nield, aged five years, the testimonial on vellum of the Society for the Protection of Life from Fire "in recognition of his conspicuous bravery" in rescuing a younger brother (aged two years) when their home was burned down. They were sleeping together, no one else being in the house, when James awoke to find the bed in flames. He dragged his brother down to the kitchen below, where they stayed till the ceiling was burned through. The elder then unfastened the back door and took his brother into an outhouse, where they remained till found by the neighbours. The boy had his wits about him and remained cool in very trying circumstances and his whole conduct is remarkable in a child of five.

March 14th.

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

Cardiff Infirmary.

The energy displayed during the past few years by the board of management of the Cardiff Infirmary has resulted in placing that institution among the best managed and best equipped in the country. In an appeal made five years ago the board pointed out that certain improvements and extensions were absolutely necessary and the cost of each was set out in some detail. These have at length all been completed at a cost of £17,822, towards which sum about £12,000 have been contributed. There are now 178 beds available for patients, or 50 more than were in use in 1900. In spite, however, of this increased accommodation there are still usually about 200 patients, including 100 children, awaiting admission. At the annual meeting of the governors of the infirmary held on Feb. 28th it was stated that the expenditure in 1904 was £13,130 and the income £11,477. The average daily cost per bed in 1904 was 9·4*d*., compared with 9·65*d*. in 1903. The number of patients treated in the wards in 1903 was 1919 and in 1904 it was 2144. Of the latter number 1164 were in the surgical wards, 303 in the medical wards, 428 in the ophthalmic wards, and 249 in the gynæcological wards. Owing to the increased and increasing work of the infirmary it has been found necessary to appoint an additional house surgeon so that the resident medical officer is now assisted by a house physician and two house surgeons.

Public Mortuary for Cardiff.

It is nearly five years since the Cardiff corporation decided to build a public mortuary and obtained the sanction of the *Local Government Board to* borrow £1500 for the purpose. Delay occurred in obtaining land but the buildings have now been completed. They are situated in a street off the Penarth road and include one room with accommodation for seven bodies and another for three bodies. In the latter there is a large inspection window through which bodies can be viewed for the purpose of identification and by jurymen. There is in connexion with the buildings a well-arranged *post-mortem room* which is provided with a revolving post-mortem table made of Doulton ware.

Swansea General Hospital.

At the end of last year the board of management of the Swansea Hospital had seriously to consider the financial position of the institution. Compared with three years ago the indoor patients had increased by nearly one-third but the available income had not shown a corresponding expansion. There are 133 beds in the hospital and there are nearly always more than 100 occupied, in some weeks the daily number of patients averaging 125. The board decided to make an appeal for more support and to leave the governors to decide as to the propriety of closing one of the wards. The result of this decision has been that at a meeting held on March 1st the financial report was so satisfactory that it was resolved to keep all the wards open. The working men of the district have been approached and they are to be asked through their trade union lodges to contribute one penny weekly per man to the funds of the hospital. The management of the hospital is by no means extravagant for the average annual cost per bed is only £60. The only adverse criticism which the board of management has had to meet is the statement that patients are admitted for treatment who are well able to pay a general practitioner. This is a matter which might properly be inquired into by the medical men in the town.

A County Medical Officer of Health for Somerset.

The question of appointing a medical officer of health for the county of Somerset is again being discussed and at a meeting of representatives from rural district councils held at Taunton on March 2nd a motion was carried deprecating the appointment of such an official and expressing the opinion that "the present arrangement by which each of the rural and urban districts in the county is under the supervision of a qualified medical officer of health secures a sufficient oversight of the sanitary arrangements of the county from a medical point of view." As a commentary upon this proposition and to illustrate the manner in which some of the Somerset councillors desire to administer the Public Health Acts an account may be given of the proceedings at a special meeting of the Glastonbury town council held to consider the advisability of prosecuting in the case of a boy who, it was alleged, in spite of being warned by the sanitary officers and whilst in the infectious stage of scarlet fever, was delivering turf from house to house. One councillor said he was afraid that if the case was reported in the papers it would have a pre [illegible] the town and an alderman [illegible] keep these things the bett [illegible] prosecute but the medical officer of health was instructed to explain to the magistrates that the council did not desire to press the case.

Hospital Sunday Fund at Bristol.

Up to the present time £1957 have been received as the result of the collections on Hospital Sunday which was recently observed at Bristol. This amount is £221 in excess of the total for 1904 and is £178 beyond the highest previous collection. There have been 396 collections in various places of worship in Bristol and the neighbourhood for the fund this year.

March 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

THE report of the gentleman who was employed by the Irish Medical Association to investigate the grievances of medical officers in Ireland has never appeared in full, while the portions of it which have appeared in the public journals have caused much adverse comment, inasmuch as it would appear that they referred to matters out of the range of the terms of reference. It *contained criticisms* on the Royal Colleges which were entirely uncalled for. Sir William Thomson and Sir Thomas Myles have both written and spoken strongly on the subject, and at *a meeting of the* council of the Irish Medical Association a motion was adopted dissociating from the council's *programme* "with no uncertain voice all the offensive statements in the report which refer t [illegible] Physicians and the [illegible]

Mr. R. M. Blake, m [illegible] dale district, Co. Louth, member of council of the Irish Medical Association and vice-president of the Poor-law *Association* of Ireland, has written to the Irish daily papers of March 13th *demanding the publication of Surgeon-*General G. J. H. Evatt's report on the best means of reorganising the Irish Medical Association. He points out that Surgeon-General Evatt was asked by the Irish Medical Association to prepare such a report, he on his side bargaining that it should be published in its entirety. Mr. Blake says that the ostrich policy will not do and in common with many other members of the association he demands the *publication of the full document.*

Dublin Sanitary Association.

The annual general meeting of the Dublin Sanitary Association was held on March 2nd in the hall of the Royal Dublin Society, Leinster House. The report which was read noted the fact that infant mortality in Dublin had shown no diminution, while the number of deaths in infants in whose case no cause of death had been certified was still very large. As regards tuberculosis it was stated that voluntary notification had not proved successful—"it must be no notification or compulsory notification" being the words of the report.

Health of Belfast.

Between Jan. 22nd and Feb. 18th 187 cases of zymotic disease have been notified—viz., 55 of scarlet fever, 38 of simple continued fever, 34 of diphtheria, 32 of erysipelas, 20 of typhoid fever, four of puerperal fever, and two each of small-pox and membranous croup. The cases of scarlet fever are very mild and typhoid fever is rapidly diminishing. Diphtheria is increasing and though measles is prevalent the deaths are not numerous. Only two cases of small-pox have occurred during the month. The number of cases of small-pox admitted to Purdysburn Isolation Hospital since the beginning of the outbreak has been 191; of these 168 have been *discharged convalescent, nine have died*, and 14 *remain* in hospital. In the reception house for "contacts" 672 persons were admitted during the same period and of these only 12 at present remain. This small-pox outbreak—a preventable disease—has cost the ratepayers of Belfast £5000. The annual death-rate for Belfast was 22 per 1000 for the past four weeks.

Poor-law Reform: the Tramp Nuisance.

Dr. J. S. Darling, medical officer of Lurgan workhouse, has drawn up a report which a committee recommended the *guardians to adopt and which stated that* tramps might be roughly divided into three classes:—1. The professional tramp who never was and never meant to be anything else, who cohabited with a woman of the same class, and whose children *necessarily grew up to the same class.* 2. Persons who, having formed drunken, lazy habits, would not remain in any employment and whose tendency was to fall more and more into the first class. 3. Those who were really seeking work and ought to be helped. The problem confronting the State was, he considered, that of compelling the idle class to cease to be parasites on the industrious, while preventing those who had not sunk to complete vice from going lower by providing them with some means of having their habits of inc [illegible] in [illegible] inc [illegible] mode of life."

March 14th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Fracture of the Superior Maxilla.

AT the meeting of the Surgical Society held on March 1st M. Sebileau showed a patient who had had his face smashed in by the passage of the wheel of a cart. He was admitted to hospital with a comminuted fracture of the malar bone and a very peculiar fracture of the superior maxilla consisting in a complete separation of the whole of the alveolar process. For the repair of the damage M. Delair, who is in charge of all matters involving the manufacture of prothetic appliances for M. Sebileau's patients, contrived a splint consisting of an aluminium plate which fitted inside the mouth. The plate was held in position outwardly by a three-branched arrangement taking its bearing from the forehead and the occiput. The result was altogether excellent. The process united firmly and the restoration of the palatine arch was so perfect that no one examining the patient would form any idea of the extent of the injury which he had sustained.

Syphilis and General Paralysis.

At two successive meetings of the Academy of Medicine, on Feb. 22nd and 28th, Professor Fournier read an important paper upon the relations between syphilis and general paralysis and treatment with a view to prevent the onset of the latter. According to Professor Fournier the great majority of cases of general paralysis occur in old cases of syphilis. Other observers, however, consider that syphilis is not the only cause of general paralysis and in view of the fact that cases of syphilis are extremely common they consider that general paralysis is not so common as it would be were it always due to syphilis. Anyway it is an indisputable fact that in nearly every patient affected with general paralysis there is a history of syphilis and, moreover, of syphilis which has been treated improperly. Professor Fournier gave some striking statistics. General paralysis is unknown in the first two or three years of syphilis, it is common between the sixth and the twelfth year, and most common of all about the tenth year. The predisposing cause is syphilis which has not been treated at all or more commonly that which has only been treated for two or three months—i.e., until the disappearance of the secondary symptoms. General paralysis most frequently occurs in patients who have had a slight attack of syphilis and who therefore have only been treated for a short time. Professor Fournier considered that the treatment of syphilis was far from being what it should be. The disease should be treated according to a definite system. For the first two years the treatment should be intensive, then the patient should have a year's rest, then there should be another year's treatment, then two years' rest, and finally another year's treatment. If any one organ appears particularly liable to the effects of the poison of syphilis special attention should be paid to it. No treatment is of any avail for general paralysis when once it is declared and the only thing to do is to prevent the syphilitic poison from bringing about that terrible affection. On March 7th the Academy resumed the discussion and M. Raymond who spoke first said that for his part he agreed with Professor Fournier as to the enormous frequency of syphilis in cases of general paralysis. Heredity, however, played a large part by giving rise to degenerations which prepared the soil, so to speak, for syphilis to bring about general paralysis. This latter complaint was common in emotional persons in whom reflex congestive conditions were rapidly and easily produced. General paralysis had been observed even in children. M. Joffroy, on the other hand, disagreed with Professor Fournier. In his opinion there was no such thing as syphilitic general paralysis. In many countries, for instance, in Bosnia, Tunisia, Ethiopia, India, and Japan, the reports of medical men showed that syphilis attacked an enormous proportion of the population, as much as 80 per cent. in Abyssinia, but general paralysis was unknown. General paralysis, said M. Joffroy, can appear in patients who have undergone a carefully carried out mercurial course and, moreover, he had seen cases in which the mercurial treatment only accelerated the onward march of the paralysis.

A New Sanitary Committee.

The Minister of the Interior has just nominated a new committee called, "Comité Consultatif d'Hygiène Pénitentiaire," to which will be referred all questions of prison hygiene, more particularly those concerning "light labour" (*travaux aux infirmeries*), and prophylactic or hygienic measures to be taken. The committee, which consists of 17 members, includes one inspector-general of the Sanitary Service, four medical men who have already served on committees nominated by the Minister of the Interior, and two medical men in the prison service.

ERRATUM.—In the fifth paragraph of the letter from our Paris correspondent which appeared in THE LANCET of March 11th occurs the phrase, "a solution of the venom is freed from all germs, being both microbicidal and antivenomous." After the word "germs," the words "the action of radium" should be inserted.

March 14th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Licence Fees of Medical Practitioners in Calcutta.

MEDICAL practitioners in Calcutta are the victims of a peculiar form of local taxation. By the Municipal Act they are divided into two classes: (1) practising surgeon, physician, and dentist, who pay 50 rupees as a licence fee annually; and (2) practising licentiate of medicine and practising apothecary who pay 25 rupees only. It has hitherto been the practice for M.B.'s of the University of Calcutta to pay at the lower rate but the question of their liability having been raised it has been decided that they belong to the first class and that the lower rate is for persons who hold a licence from any body or university to entitle him to practise medicine. As there is no registration and anybody can hold a presumed licence to practise from any self-constituted or other worthless college the legal decision can only be considered of value for the purposes of taxation. That the licentiates of the University should be classed with practitioners who only hold bogus or other unrecognised degrees is a distinct reflection upon their training; on the other hand the difference between M.B. and L.M.S. of the University is hardly sufficient to warrant the former being overtaxed for the whole of his practising life.

Accelerated Promotion in the Indian Medical Service.

It is notified that the promotion of an officer of the Indian Medical Service to the rank of major may be accelerated if he produces while in the rank of captain satisfactory evidence of progress in any branch of knowledge which is likely to increase his efficiency, such as obtaining a higher degree, or a special qualification of repute, or by furnishing proof of having pursued with diligence and advantage serious study of an approved subject. The period of acceleration that may be granted is fixed at six months provisionally.

The New Water Supply for Rangoon.

Rangoon may congratulate itself on having obtained a pure and abundant supply of water. The new Hlawga waterworks consists of a reservoir about seven miles long and from one and a quarter to two miles wide. It is estimated to provide for a population of 650,000, at an average consumption of 25 gallons per head daily. At the present time the consumption is about 40 gallons per head and at this rate the supply is sufficient for 400,000 persons The new reservoir can be even extended much further at a comparatively trifling cost so that there is no likelihood of continuance of the scares of scarcity of water to which Rangoon has been periodically subjected in the past.

The Plague Epidemic: its Mortality and Continued Extension.

The magnitude of the plague mortality which has been recorded for some weeks past has so come to be an annual occurrence that it seems almost as if familiarity with the terrible death roll had bred contempt for it. For the week ending Feb. 11th there were recorded throughout India 33,660 deaths, as against 36,117 for the week preceding. It is curious that a small decline has been noticed in Bengal, United Provinces, the Punjab, and some other places, but by comparing the course of the disease with that followed last year it is too much to hope that it is more than a temporary set back. The outbreak in Bombay city is growing rapidly, 511 deaths being recorded, as against 395 for the preceding seven days. In Calcutta also the recrudescence is unmistakeable. Other figures of importance are as follows: United Provinces 14,438, as against 15,367; the Punjab 8419, as against 9472; Bengal 4926, as against 5150; Bombay districts 2755, as against 3161; Rajputana 799, as against 603; Hyderabad State 550, as against 526; Central Provinces 438, as against 467; Mysore State 301, as against 346; Burmah 9, as against 1; and Calcutta 106, as against 84. The outbreak at Rangoon is unfortunately increasing. It has been decided to do away with the plague segregation camp and to let the cases be treated either at the contagious diseases hospital or in private houses. This plan has been adopted to prevent a scare. This is following the experience obtained elsewhere—viz., that it is the regulations which the ignorant people become alarmed at and not really the disease. In fact, the apathy shown when the people are being decimated by cholera, plague, or small-pox is extraordinary, while the mildest regulation which causes any restriction is met by active as well as by passive resistance. It is perhaps too early to describe the outbreak in Madras as recent because the city is by no means safe from a further development. The prompt measures taken are deserving of the highest praise because they were not only energetic and stringent but liberal. There have been from time to time some 60 imported cases of plague in Madras but they have been ferreted out and appropriately dealt with and the disease has not spread. In this instance, however, a small outbreak had actually become established before it was discovered. The patients were immediately removed and the whole village, consisting of 118 huts, was burnt down. The Mauritius emigration depôt close by was probably the source of the mischief, as dead rats showing plague bacilli were discovered close to it. This depôt receives coolies from all parts of the province. Every rat burrow was dug up and every rat found was killed, while a reward of 6 pies (=½d.) per head for every rodent brought in daily bags. The displaced villagers were liberally provided for and the old site has been abandoned. The success of Madras is probably due to the fact that in the neighbourhood of this emigration depôt the population was not thick and there were not many rats, but the thoroughness of the operations was equally necessary to stamp out the disease completely. Had the outbreak occurred in the city there is every likelihood that it would have spread.

Feb. 24th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Bubonic Plague.

BUBONIC plague continues in New South Wales and Queensland. At Ulmarra, near Grafton, six cases have proved fatal. Exception has been taken by the Sydney press to the action of the Board of Health in removing plague patients from Ulmarra to the Grafton Hospital. Grafton is a sea port and the usual shipping restrictions are being enforced, ships not being allowed to come to the wharves and no produce is allowed to go from infected districts. Several cases have occurred in Brisbane and it is believed that the infection of the Ulmarra cases can be traced to Brisbane. In Victoria the Board of Health has revised the regulations for the berthing of ships and urged the importance of continued vigorous destruction of rats.

Infectious Disease in Victoria.

The returns presented to the Board of Health of Victoria for the fortnight ending Jan. 14th showed that the number of typhoid fever cases reported was 98, four of which had resulted fatally. In the corresponding period of 1904 there had been eight deaths out of 133 cases. For the metropolitan area there had been 28 cases, resulting in two deaths, as against 4 [illegible] last year. [illegible] the fortnight ending [illegible] 45 cases, 4 deaths; 1905, 52 cases, 1 death; for the metropolitan area: 1904, 15 cases, 2 deaths; 1905, 22 cases, 1 death. For the fortnight ending Jan. 14th the comparison in regard to scarlet fever cases reported in 1904 and 1905 respectively was:—For the whole State: 1904, 36 cases, 1 death; 1905, 18 cases, 1 death; for the metropolitan area: 1904, 29 cases, 1 death; 1905, 7 cases, no deaths.

Vital Statistics of New South Wales.

The Government statistician of New South Wales has published the vital statistics of that State for the year 1904. He says:

> There has been a su [illegible] marriages and births and a substanti [illegible] year the births numb [illegible] the excess over the [illegible] number of births is [illegible] year, as will be seen from the following statement of the two years 1903 and 1904 —

Births.

Quarter ending—	1903.	1904.
March 31st	8827	8,876
June 30th	9009	9,635
Sept. 30th	9001	10,209
Dec. 31st	9129	9,977

The birth rate represents an average of 26·77 per 1000 of population [illegible] statement:—

Deaths.

Quarter ending—	1903.	1904.
March 31st	4539	3884
June 30th	4040	3917
Sept. 30th	3821	3935
Dec. 31st	4097	3674

> The number of marriages celebrated in the State during the year 1904 was 10,429, which [illegible] number than was regi [illegible] 1902 alone excepted. [illegible] or 14·42 persons mar [illegible] favourably with the [illegible] preceding ten years.

Preservatives in Milk.

Prosecutions of milk-vendors for selling milk containing preservatives continue in all the States. At the Glebe court on Jan. 18th a milk distributer doing a very large business was heavily fined for selling milk which contained three grains of formalin to the gallon and added water to 8½ per cent. In two other cases of a similar character fines were inflicted. At the Newtown court several almost identical cases were dealt with.

Hospital Affairs.

An interesting account of the work of all the Sydney hospitals for the year 1904 has just been published. At the five metropolitan hospitals 72,160 patients received treatment distributed as follows:—

> Sydney 32 188; Royal Prince Alfred Hospital, 15,846; St. Vincent's [illegible] follows in Sydney [illegible] 445; Children's [illegible] 2220; St. Vincent's [illegible] Hospital, 301.

—The annual meeting of the Sydney Hospital was held on Feb. 1st, the State Governor presiding. The report was highly satisfactory and the finances appear to be sound, the income sufficing to meet the expenditure. It was stated that—

> Perhaps the highest tribute that could be paid to the members of [illegible] the fact that the total number [illegible] those [illegible] ghest [illegible] results

—The Government of Victoria still declines to allow the Kronheimer wing at the Austin Hospital to be opened for the reception of advanced cases of consumption. Instead it proposes to erect a sanatorium at Broadmeadows on an area of 300 acres of Crown land, 500 feet above sea-level and three and a half miles from the Somerton railway station. The objections to this proposal are the want of a proper water-supply and the distance of the site (about 13 miles) from the metropolis. The Premier also proposes to establish an epileptic colony on the same site.—Trouble has occurred at the Ararat Hospital (Victoria) owing to a proposal of the committee to allow the resident medical officer private practice. The honorary medical officers objected and as the committee persisted the honorary staff resigned. The committee has now requested the Chief Secretary to permit the medical superintendent and medical officer of the Ararat Hospital for Insane to visit the hospital and to administer anæsthetics when requested by the resident medical officer.

Charge of Perjury against a Medical Man; Case withdrawn.

The case adjourned from last month in which Mr. Paris Nesbit, K.C., of Adelaide, proceeded against Dr. R. E. Schlesinger of St. Kilda for perjury in signing a lunacy certificate, was resumed at the St. Kilda court on Feb. 1st. After recalling a witness Mr. Nesbit said that he had decided to proceed no further with the case as he would inflict great pain on a lady whose name had been mentioned in the proceedings and that he had attained his object by the publicity given to the methods of medical men. The police magistrate said that the only evidence touching the matter was that given by Mr. Nesbit himself and that there was nothing in the evidence to justify a committal.

Obituary.

Dr. Thomas Harrison of Granville, New South Wales, died at the age of 53 years, from spinal meningitis. He had been practising in the district for 11 years and was very popular. He was medical officer to the various local friendly and benefit societies and was a prominent member of the Masonic fraternity.—Mr. Ralph Hodgson died very suddenly at Neutral Bay, at the age of 50 years. He was a son of the late Captain C. G. Hodgson of the Grenadier Guards. Besides his active practice Mr. Hodgson took a great interest in many outside affairs. He was a marine motorist, a great chess player, and president of the Sydney School of Arts Chess Club. He was also a politician and an active member of the Reform League. —Mr. J. Harris Lawrence of Port Arlington, Victoria, was found dead in his surgery on Jan. 16th and at the inquest was found to have committed suicide by narcotic poisoning. He was 49 years old and came to the district last November from Bath where he has left a widow and five children and where his father and brother are engaged in medical practice.

Feb. 7th.

Obituary.

EDWARD ATKINSON, M.R.C.S. ENG., L.S.A., F.L.S.

Mr. Edward Atkinson, one of the oldest and best esteemed members of the profession in Yorkshire, died at Harrogate on March 1st at the age of 75 years. His father was Mr. John Atkinson, solicitor, of Leeds; his mother was the daughter of the second William Hey and grand-daughter of the more famous William Hey, F.R.S. He was educated at Leeds Grammar School and in his "teens" went to sea for some time. He then became a medical student at King's College and enjoyed the great privilege of being "house pupil" to Sir William Bowman. Shortly after his appointment as house surgeon at King's College Hospital there was a demand for some young surgeons to go out to the Crimea in consequence of the lamentable breakdown of the Army Medical Service and he was one of the chosen band, together with Mr. Hulke, Sir Spencer Wells, Mr. Christopher Heath, and others. He was attached to the hospital at Scutari where Florence Nightingale was working. In 1855 he became assistant surgeon at the British Civil Hospital at Smyrna and in 1856 surgeon to the English Hospital and the Prussian Deaconesses' Hospital at Jerusalem. Returning to Leeds in 1860 he entered into partnership with his uncle William and his cousin Samuel Hey. Mr. Atkinson was an ardent naturalist and lectured for some years on botany at the Leeds School of Medicine, where he was subsequently one of the lecturers on surgery, such changes of subject being not uncommon in those days. He served on the staff of the Leeds Public Dispensary and was surgeon to the Leeds Infirmary from 1884 to 1894, when he became consulting surgeon. He was president of the Leeds and West Riding Medico-Chirurgical Society in 1887 and of the Leeds Philosophical and Literary Society in 1885-86, to which society he was also honorary curator in zoology, and was one of the original members of the Leeds Priestley Club. He also rendered 30 years of service to the St. John Ambulance Association in Leeds and district and he was an honorary associate of the Order of St. John of Jerusalem. He made various contributions to literature both on biological and medical subjects.

Mr. Atkinson's students, of whom the writer of this obituary notice is one, remember him with very kindly feelings. A gentleman of the old school, cultured and broad-minded, a courteous and genial teacher, friend, and colleague, always ready to talk of his eastern life and travels and of the natural sciences in which he took so much interest, his loss is mourned by many to-day. He was buried at Silverdale on Morecambe Bay by the side of one of his sons who was drowned at this place in 1872. He leaves a widow and eight sons, the eldest of whom is Mr. F. E. Atkinson, medical officer of health of the Craven combined district.

JOHN FRANCIS SCOTT FOWLER, M.B., C.M. ABERD.

THE death occurred on March 3rd, at Georgetown, British Guiana, of Dr. J. F. S. Fowler, surgeon at the Colonial Hospital there. Dr. Fowler was born in St. Helena 40 years ago. He received his professional training at the University of Aberdeen, where he graduated M.B., C.M. in 1885. He was married to a daughter of Mr. David Sinclair of Aultens.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.— The deaths of the following eminent foreign medical men are announced:—Dr. Adolf Bastian, professor of ethnology in the University of Berlin, at Trinidad, whither he had gone in pursuit of his anthropological studies. He was the founder of a great popular museum in Berlin and although nearly 80 years of age he never ceased to take the keenest interest in it. He was a man of marvellous industry and of encyclopædic knowledge.—Dr. Pasquale Penta, *privat-docent* of mental diseases in the University of Naples.—Professor Andrei Vassilyevitch Chodin, who occupied the chair of ophthalmology in the University of Kieff, and for 20 years edited the *Ophthalmological Gazette*.

Medical News.

TRINITY COLLEGE, DUBLIN.—At the final examination in medicine held in Hilary term the following candidates were successful:—

Eva J. Jellett, William J. Powell, Charles R. M. Morris, Robert Magill, William Hassard, William R. Galwey, William F. Samuels, John Murdoch, Henry E. M'Cready, and Cecil Scaife.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn*: Dr. Grube has been recognised as *privat-docent* of Physiology. Dr. Ribbert of Göttingen has accepted the invitation to the chair of Pathological Anatomy, together with the direction of the Pathological Institute.—*Breslau*: Dr. Ulrich Gerhardt of Würzburg has been recognised as *privat-docent* of Zoology and Dr. Schroeder as *privat-docent* of Psychiatry.—*Budapest*: Dr. P. Kuzmik, *privat-docent* of Surgery, has been promoted to an Extraordinary Professorship.—*Giessen*: Dr. Brüning has been recognised as *privat-docent* of Surgery. —*Gottingen*: Dr. Max Borst of Cologne has been offered the chair of Pathological Anatomy in succession to Dr. Ribbert. —*Greifswald*: Dr. Wittmaak has been recognised as *privat-docent* of Otology.—*Marburg*: Dr. Schridde has been recognised as *privat-docent* of Medicine.—*Odessa*: Dr. Bukoiemski has been promoted to the chair of Gynæcology.—*Padua*: Dr. Domenico Taddei has been recognised as *privat-docent* of External Pathology.—*Pavia*: Dr. Rosario Traina of Bologna has been recognised as *privat-docent* of Pathological Anatomy.—*Prague* (*German University*): Dr. Rudolf Fick of Leipsic has been offered the chair of Anatomy in succession to Dr. Rabl who goes to Leipsic.—*Rome*: Dr. Alesso Nazari has been recognised as *privat-docent* of Pathological Anatomy.—*Tomsk*: Dr. S. Lobanoff of St. Petersburg has been appointed to the chair of Ophthalmology, in succession to Professor Erophêieff, resigned.—*Turin*: Dr. Romeo Mongardi has been recognised as *privat-docent* of Otology and Laryngology.—*Zurich*: A professorship of physical methods of treatment is being established; also an institute where baths, electro-therapy, massage, gymnastics, &c., will be carried on.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—Mr. R. T. Newstead, who for several years has acted as external examiner in entomology in the University of Edinburgh, having previously been assistant to the famous entomologist, the late Miss Eleanor Ormerod, has been appointed lecturer in economic entomology and parasitology in the Liverpool School of Tropical Medicine.

BRISTOL MEDICAL MISSION.—The annual meeting of the friends of this institution was held on Feb. 28th. The medical report stated that during 1904 about 9000 cases had been treated. 2154 visits had been paid to patients at their own homes and there were 26,728 attendances at the dispensary. The financial statement showed an unfavourable balance of £14.

CHORLEY AND DISTRICT MEDICAL SOCIETY.—A meeting of medical men was held in the Shepherds' Hall, Chorley, on March 2nd, at which the following motions were proposed and carried unanimously:—

(1) That a society be formed for the discussion of subjects interesting [illegible] hospital be an honorary member.

THE UNIVERSITY OF LONDON AND TROPICAL MEDICINE.—In response to petitions presented by the London School of Tropical Medicine in February, 1904, the Senate of the University of London has decided to institute a sixth branch of study—viz., tropical medicine—in which candidates may be examined for the M.D. degree and has admitted the London School of Tropical Medicine as a school of the University in the subject of tropical medicine. The University of the metropolis of the empire has thus recognised its imperial character and has brought itself into line with Cambridge and other universities in regard to the importance of the health of Europeans and natives in the great tropical dependencies of the nation. These facts will be emphasised at the banquet, over which Mr. Chamberlain will preside, on behalf of the London School of Tropical Medicine on May 10th.

PRUDENTIAL ASSURANCE COMPANY.—The fifty-sixth annual report of this company now lies before us. One of the first things noticeable is that in the industrial branch for the year ending Dec. 31st, 1904, the medical fees paid amounted to but £51,738 3s. 10*d*., against £55,875 1*s*. 9*d*. for the previous year. This looks as if the medical profession has not received so much this year by the sum of £4136 17*s*. 11*d*.; but wherefore we know not. Certainly in this branch the company has added 310 more agents and the number of policies in this branch has increased by 286,378. Taking the ordinary and the industrial branches together the number of deaths during the year was 240,154, against 217,450 in the previous year. The premiums received during the year amounted to £9,948,351—an increase of £286,941 over the year 1903, and the assets on Dec. 31st, 1904, were valued at £55,359,505, being an increase of £4,142,128 over those of 1903. Ten years ago the assets of the company in both branches amounted to but £21,213,805 and ten years before that the company was proud to advertise that "the invested assets exceed four and a half millions."

TRAINED NURSES' ANNUITY FUND.—The occupation of a nurse in many cases involves much hard work and anxiety, while those who attend private patients have in addition to reckon with occasional want of employment. Increasing years or any form of ill-health seriously interferes with a nurse's prospects and although there are a few excellent institutions which render aid in such circumstances many nurses are for various reasons unable to avail themselves of it. To meet such cases the Trained Nurses' Annuity Fund, of which H.R.H. Princess Christian is now president, was instituted in 1874 and at present grants annuities of £17 each to worn-out nurses. Candidates for election as annuitants must have had at least three years' training and 15 years' nursing, must have attained the age of 50 years, and must be more or less incapacitated for work. The council in appealing for public support claims that no other society meets the needs of the cases which this fund assists. The treasurers of the fund are Messrs. Coutts and Co., bankers, Strand, London, W.C., and the secretary's office is at 73, Cheapside, E.C.

UNIVERSITY OF CAMBRIDGE.—Mr. T. S. P. Strangeways of St. John's College has been appointed the first Huddersfield Lecturer in Special Pathology on the new foundation recently established in the University.

REPORT OF THE COMMITTEE ON VACCINATION EXPENSES.—The report of the Departmental Committee of the Local Government Board upon the question of vaccination expenses has just been presented to Parliament and we hope in a future issue to comment fully thereon.

HEALTH OF BARNSTAPLE.—Mr. J. R. Harper, the medical officer of health of Barnstaple (Devon), in his annual report for 1904, which has just been issued, states that the estimated population of the town was 14,258. The birth-rate and the death-rate were respectively 22·72 and 15·42 per 1000, the death-rate being the lowest for some years. The infantile mortality was at the high level of 160·49 per 1000 births.

ROYAL DENTAL HOSPITAL, LEICESTER-SQUARE.—The annual general meeting of governors was held at the hospital on March 14th, Mr. John Tweedy, President of the Royal College of Surgeons of England, being in the chair. [illegible] posed of [illegible] aid that [illegible] he hos- [illegible] 42,000 [illegible] l suffer- [illegible] ulated. [illegible] e mere avoidance of pain and shock. The knowledge that a patient was not suffering gave greater freedom of action to the surgeon and added to the thoroughness and efficiency of his endeavours. Exemption from physical suffering could not, howeve [illegible] risk. [illegible] to pai [illegible] safety. [illegible] anæsthetics and that was an unequivocal testimony to the care and skill of those who were intrusted with their administration. He was impressed by the special provision made at the hospital for the care and treatment of the teeth of children. It would be impossible to over-estimate the value and importance of that department. Last year an inter-departmental committee inquired into the alleged physical deterioration of the people of these islands. That inquiry had its inception in a memorandum drawn up by the then Director-General of the Army Medical Service on the physical unfitness for military service of a large proportion of those who offered themselves for enlistment. In the year 1902 no less than 40 per cent. of those who offered themselves as recruits were rejected on account of decay or loss of teeth. That fact had a grave significance; there was perhaps no single condition more inimical to physical well-being, especially in adolescence, than defect or disease of the teeth. And physical well-being was no small factor in moral well-being. It was certain that much of the loss and decay to which he had referred would have been prevented by the exercise of intelligent care and forethought. Institutions such as the Royal Dental Hospital did a great national service by impressing upon the community, and especially upon the poorer classes, the necessity of bestowing greater attention on the care and cleanliness of the mouth and the teeth. But such an institution was not only an agency for the dissemination of useful hygienic information and for the relief of actual suffering, it was also a centre for the improvement of dental skill and knowledge and a school for the training of practitioners may be as important as a hospital for the treatment of those who seek for relief. As hospitals the benefits they conferred, great though they might be, were limited to the patients themselves. But as schools their benefits were indefinitely multiplied and ultimately reached the whole community. For that reason such institutions were entitled to liberal support from every section of society. Hospitals, moreover, subserved a higher ethical purpose. Much of the work done within their walls was voluntary, and the spirit which prompted members of the medical and dental professions to undertake those self-imposed and often self-sacrificing labours reacted upon the character of those who rendered the services and those who received them. Medical charity engendered mutual trust between patient and practitioner and helped to establish between them relations of the best kind. Thanks to the voluntary principle a value was set upon work done in and for itself without any consideration of material recompense. The first and only consideration was the character of the service rendered and the virtue of the work performed; the only reward thought of or desired was the reward of a good conscience and the satisfaction which good work well done always afforded.

MILLER *v.* MILLER AND FOWLER: A CONGRATULATORY DINNER TO DR. C. O. FOWLER.—It is proposed to entertain Dr. Fowler at a dinner to be held in about a month's time in recognition of his complete exoneration from the disgraceful charges brought against him in recent divorce proceedings. A meeting of the medical profession of Croydon and district will be held at the Public Hall, George-street, Croydon, on Monday evening next, March 20th, at 8.30, to make all necessary arrangements. Communications should be addressed to Mr. C. M. Fegen, Town Hall, Croydon.

MEDICAL CONFERENCE ON THE TEACHING OF HYGIENE AND TEMPERANCE.—The medical conference which has been arranged to take place at the Examination Hall, Victoria Embankment, W.C., on Friday next, March 24th, at 5 P.M., will be an important meeting. It has for its main purpose the consideration of the value and the desirability of the teaching of hygiene and temperance in the schools of the country. The medical profession has been taking keen interest in the subject, as is evidenced by the fact that no less than 14,718 of its members last year signed the petition in favour of such teaching being made compulsory. It is desirable that all advance on this line should be on thoroughly sound principles and it is therefore opportune that such a conference has been arranged in order that the profession in London may have a further consideration of the matter. Sir William H. Broadbent will occupy the chair and Sir Victor Horsley will state the present position of the scheme in reference to the teaching of hygiene and temperance in schools. He will be followed by Dr. Robert Jones who will draw attention to the report of the Inter-departmental Committee on Physical Deterioration in so far as it deals with the matter. Sir Thomas Barlow will indicate the present position of the profession in relation to alcohol, and Mr. W. McAdam Eccles will introduce the question of the pharmacological and toxic properties of alcohol and how they might be more fully taught in the medical schools with advantage to the nation. At 5.45 discussion will be invited and we understand that Dr. William Collier, Dr. F. W. Mott, Mr. A. Pearce Gould, and others may take part in it. The meeting is to terminate at 6.30 P.M.

UNIVERSITY OF LEEDS.—A meeting of the court was held on March 8th when it was decided that the medical degrees shall be Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). Provision was made for the exemption from examinations and courses of study of students of the Yorkshire College or the Victoria University of Manchester, in order that students may be at no disadvantage in consequence of the changes which have recently taken place. The following recommendations of the Senate as to *ad eundem* degrees were adopted:—

> I. As to conferment of *ad eundem* degrees on students who have attended full courses of study at the Yorkshire College and have graduated at various universities but who have not been admitted to the College Associateship: (*a*) That graduates of the Victoria University be offered the same degrees in the University of Leeds as those which they have received from the Victoria University; (*b*) that graduates in medicine of other universities be admissible on application to the M.B. degree of the University of Leeds; (*c*) that applications from other university graduates who have been students of the Yorkshire College be considered on their merits.
>
> II. As to Associates of the Yorkshire College: (*a*) That graduates of the Victoria University be offered the same degrees in the University of Leeds as those which they have received from the Victoria University; (*b*) that graduates of other universities be offered the degree of Bachelor in this University in the faculties in which they graduated elsewhere; (*c*) that the question of the admission to degrees of Associates *honoris causâ* be deferred.

It was also decided that all persons admitted to degrees of the University of Leeds under the foregoing conditions shall be admissible as life members of convocation and also that no graduate so admitted to a degree shall be precluded from proceeding in the University of Leeds to a higher degree in his particular faculty. It was also decided to confer the honorary degree of M.Sc. upon members of the staff of the Leeds Infirmary who are also members of the Faculty of Medicine in the University. The Council was authorised to grant to any professor of the University or to any lecturer who is the head of any department in the University a degree not higher than that of Master of the Faculty in which he has graduated, or in the case of a professor or lecturer holding no degree, such degree not higher than that of Master as the Council may determine. The Council was also authorised, if it thought fit, to grant to any other officer of the University such degree not higher than that of Master as it might determine, but no such degree shall be conferred until a report thereon has been received from the Senate.

UNIVERSITY OF LONDON: FACULTY OF MEDICINE.—A meeting of the Faculty will be held at 5 P.M. on Friday, March 24th, at the University. The Faculty will elect a Senator in place of Sir Cooper Perry who is unwilling to accept nomination for re-election. The Dean will make a statement as to the progress of the Institute of Medical Sciences scheme and also on a matter connected with the visit of British physicians and surgeons to Paris in May next. Dr. Cabert has given notice of motion for a committee to consider a plan of retirement for members of the boards of studies.

THE SOCIETY OF ANÆSTHETISTS.—The following officers have been selected for next session:—President: Mr. Edgar Willett. Vice-President: Mr. W. Tyrrell. Treasurer: Dr. R. J. Probyn-Williams. Secretaries: Mr. H. C. Crouch and Dr. J. Blumfeld. Auditors: Dr. N. W. Bourns and Dr. G. A. H. Barton. Council: The officers and Mrs. F. M. D. Berry, Mr. C. Carter Braine, and Dr. W. J. McCardie.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Vaccination.

THE vaccination question has been unusually prominent in these last few days. Both the Lords and the Commons have had their attention directed to different aspects of the matter and in addition there has been presented at last the report of the Departmental Committee on Vaccination Expenses. This committee was appointed in 1903 by the Local Government Board to consider whether any alteration should be made with regard to the remuneration, costs, and expenses of public vaccinators. In its report the view is expressed that the fees paid for primary vaccination might be reduced without any diminution in the efficiency which has been attained under the present system and without any injustice to the public vaccinators if the provisions of the Vaccination Orders were made more elastic so as to facilitate the adoption of special arrangements and to admit of certain modifications in the duties and status of the public vaccinators. The extent of a parent's power to require the attendance at his home of a public vaccinator to vaccinate his child might, the committee thinks, without hardship be considerably curtailed. The committee also states that in its opinion the maximum fees may be fairly and reasonably fixed at the following amounts: 2s. 6d. for every case of successful primary vaccination performed elsewhere than at the home of the child or person vaccinated, 3s. for every case of primary vaccination performed at the home of the child within one mile from the public vaccinator's residence, 4s for every case of successful primary vaccination performed at the home of the child over one mile and under two miles from the public vaccinator's residence, and 5s. for every case of successful primary vaccination performed at the home of the child over two miles from such residence. Where journeys of over three miles have to be made a special fee should be arranged between the authorities. No change is recommended in the mode of remuneration of vaccination officers or in the minimum fees to be paid to them in districts where there is no serious opposition to the enforcement of the Vaccination Act, but where there is such opposition it is proposed that the fees of these officers should be fixed at such an amount as would give them approximately the same remuneration as they would receive in a similar district where opposition to vaccination did not prevail.

Smoking among Juveniles.

Dr. Macnamara is promoting a Bill founded on the recommendation of the Committee on Physical Deterioration that legislation should be introduced to prohibit the sale of tobacco and cigarettes to children under a certain age. Briefly stated, the Bill provides that no person shall sell, give, or supply tobacco in any form to, or for the use of, any person under the age of 16 years, and the penalty for a first offence is a fine of 20s. and for any subsequent offence 40s., but after a third conviction the offending tobacconist may lose his licence. Among the supporters of the proposal are Mr. Lloyd-George, Dr. J. G. Shipman, Mr. Churchill, Sir John Gorst, Mr. Burns, Mr. Cathcart Wason, Major Seely, and Mr. Lambert.

Underfed School Children.

When the second reading of the Scotch Education Bill is reached Mr. Henderson will move as an amendment: "That this House declines to give its approval to the Bill on the ground that it contains no provision whereby the education authorities shall insure that every child under compulsory attendance at the schools in its area shall receive proper nourishment before being subjected to mental or physical instruction."

Sanitary Inspection of Schools.

It is of some interest to note that in the new Scotch Education Bill the Government proposes to put the sanitary inspection of the schools under the ordinary local sanitary authorities—the medical officer of health and the sanitary inspector.

HOUSE OF LORDS.

FRIDAY, MARCH 10TH.

The Revaccination of School Children.

[illegible] eived some strong criticism [illegible] Lord Lister in particular [illegible] nd. Lord Harris then told [illegible] luce the principle that year [illegible]

[illegible] expense for hospitals which might not be used for years, great incon[illegible] *The local authority* [illegible] l of course the sur- [illegible] All the difficulties and all the cost arose simply and solely [illegible] Parliament had not [illegible]

Lord KENYON, in reply, said that Lord Lansdowne last year spoke in favour of the Bill which the Duke of Northumberland proposed and gave no opposition to it. The Government was in favour of encouraging revaccination as far as it could, but it relied on the report of the Commission which sat in 1896 and said it conceived that compulsory revaccination was not practicable. In the first place it thought there were practical difficulties in the way. [illegible] en overcome in Germany, but it di[illegible] hem in this country and further it [illegible] hostility to vaccination throughout [illegible] ubt did say [illegible]

[illegible] negative.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 8TH.

Free Meals for Destitute Children.

[illegible] might be drawn upon for this purpose. The Lord Mayor's fund for free meals to children at Leeds was raised to meet exceptional distress. [illegible]

[illegible] ommendation of the Committee [illegible] that local education authorities [illegible] nds at their disposal to provide [illegible]

Vaccination Exemption Certificates.

Mr. WEIR asked the Home Secretary whether he was aware that on April 5th last Mr. Philip J. Cook applied before Mr. Fordham at the North London police court for a certificate of exemption from vaccination for his infant child and that although he explained that a certificate had been granted to him at that court on a former occasion for another child the magistrate declined to [illegible]

The Case of Nurse Holland.

[illegible] *Ireland whether he could* [illegible] nto the case of Nurse [illegible] f Lunacy as entirely [illegible] *hlessness in the dis-* [illegible] of her statements — [illegible] lered this case. The [illegible] s vested solely in the [illegible]

An Irish Complaint.

[illegible] matter was not one in which [illegible] was nothing to show that the reverend gentleman had done anything illegal or actionable rendering him liable to a penalty under 21 & 22 Vict., Cap. 90, Sec. 40.

FRIDAY, MARCH 10TH.

The Inspection of Meat.

Lord **GEORGE HAMILTON** asked the Member for North Hunts, as representing the Board c[illegible] his attention had been directed to the absence [illegible] ious systems of meat inspection now in local [illegible] nd whether he would consider the advisabilit[illegible] ystem of branding or certificate such as exist [illegible] which butchers and other vendors of meat who have purchased their supplies from Smithfield or some other central market under scientific inspection might be able to associate with the meat so purchased the certificate which passed the meat as sound and free from disease.—Mr. **LONG** said: My attention has been drawn to the alleged absence of uniformity as regards meat inspection by local authorities in England and I have instructed one of the medical inspectors of my department to make inquiry on the subject. I will give consideration to the suggestion of my noble friend in connexion with the report of the inspector when it is received.

MONDAY, MARCH 13TH.

The Higher Education of Nurses.

Mr. **HEALY** asked the President of the Board of Trade whether the Board had received an application for a licence to incorporate a society for the [illegible] es from gentlemen unconnected with medicir[illegible] whether the Board still adhered to the view ex[illegible] by the Board on August 6th, 1891, to Dr. Bedford Fenwick, in which it was stated that it appeared to the Board of Trade that *it was not competent to determine the very important question connected with the establishment of a register of nurses, which should be settled before the register can be effectively established*; and that, in the circumstances, the Board of Trade was unable to grant the desired licence to the Royal British Nurses Association; and that the Board was convinced that full inquiry (by competent authorities) into all the facts and circumstances of the case, and into the objections that had been raised, should precede any further steps on the part of the Government; and whether, if any change had since taken place in the policy of the Board in dealing with the question of the registration of nurses, he could indicate the nature and grounds of such change.—Mr. **GERALD BALFOUR** replied: An application has been received by the Board of Trade for a licence to incorporate under Section 23 of the Companies Act, 1867, without the word "limited," a society for the higher education of nurses. The proposed memorandum and articles of association which have been submitted to the Board of Trade are subscribed by seven gentlemen, none of whom are members of the medical or surgical professions, although one is the chairman of a London hospital. The Board of Trade proposes to hear both the applicants and the objectors to the grant of a licence and until after such hearing it is not proposed to come to any decision.

Enteric Fever in Fermanagh.

Mr. **EDWARD MITCHELL** asked the Attorney-General for Ireland whether he would say what steps, if any, the Local Government Board had taken to insist up[illegible] ng with the insanitary condition of the villag[illegible] Fermanagh; whether he was aware that at [illegible] oid fever existed and that one death at least had taken place therefrom; and what immediate action the Local Government Board intended to take in the matter.—Mr. **ATKINSON** said: It is a fact that five cases of enteric fever have occurred in this village and that one of the patients has died. A complaint has been made to the Local Government Board under the fifteenth section of the Public Health (Ireland) Act, 1896, that the sanitary authority has made default in the performance of its duty. The Board has accordingly directed a local inquiry to be held and the rural district council has been so informed.

The Sale of Poisons.

Sir **THOMAS DEWAR** asked the Secretary of State for the Home Department whether he proposed to introduce legislation this session to regulate the sale of poisons; and whether, in view of the deaths which had occurred through the taking of poisons by misadventure, notably a recent case in which a fatal dose of carbolic acid was administered to a patient under the impression that the bottle contained the prescribed medicine, he would take into consideration the advantage to be derived from a clause directing that all poisons shall be sold in bottles of a distinctive shape, so that the risk of bottles of poison being mistaken for medicine might be reduced to a minimum.—Mr. **AKERS-DOUGLAS** said: The Lord President of the Council has under his consideration the question of legislation on this subject but I am not in a position to make any statement as to the introduction of a Bill.

Mr. **REMNANT** asked the President of the Board of Trade whether his attention had been drawn to a recent judgment in the Cardiff county court in which it was revealed that a one-man company incorporated under the Companies Acts could not be punished for any disregard of the poison regulations sanctioned by the Privy Council; and whether, in the public interest, the departmental committee of inquiry on the Companies Acts would be directed to consider and report on this effect of incorporation.—Mr. **GERALD BALFOUR** replied: My attention has not been called to the recent judgment in the Cardiff county court referred to in the question. The Board of Trade is not prepared to direct the departmental committee of inquiry on the Companies Acts to consider and report on the sale of poisons by one-man or other companies, inasmuch as any amendment of the law in this respect would not be germane to a Companies Bill.

Dr. **MACNAMARA** asked the Home Secretary whether his attention had been called to the number of deaths which had recently occurred through accidental poisoning; whether he was aware that a locking poison bottle had been recently invented by which at a trifling cost accidental poisoning could be prevented; and, if so, whether he would take steps to compel distributors of carbolic acid and other virulent poisons to refrain from selling poisons except in some kind of locked bottle.—Mr. **AKERS-DOUGLAS** replied: My attention has been drawn to several recent cases of accidental poisoning and also to several inventions designed to minimise the risk of such accidents. Under the regulations made by the Pharmaceutical Society under Section 1 of the Pharmacy Act, 1868, and approved by the Privy Council, it is at the present time required that all liniments, embrocations, lotions, and liquid disinfectants containing poison must be sold in bottles rendered distinguishable by touch from ordinary medicine bottles, and that each such bottle must bear a label giving notice that its contents are not to be taken internally. The Lord President of the Council is of opinion that it would be undesirable to prescribe the use of any special form of bottle which might give a monopoly to the patentee, and further, that the inconvenience of a locked bottle might not improbably lead careless purchasers to transfer its contents into some ordinary vessel.

The Physical Condition of School Children.

Sir **JOHN GORST** asked the Secretary of the Board of Education whether the attention of the Board of Education had been directed to the evidence given in December, 1903, by Dr. Eichholz, one of its inspectors, before the Committee on Physical Deterioration, in which he testified that in a school in Lambeth he considered 90 per cent. of the children unable, by reason of their physical condition, to attend to the duties of the school in a proper way; and in many other schools in London and elsewhere he found a considerable, though less, proportion of physical deterioration, and what steps the Board of Education had taken to prevent the waste of public money involved in providing instruction for children thus unfit to receive it.—Sir **WILLIAM ANSON** said: I have carefully read the evidence referred to and have myself visited the Lambeth school referred to in the question. The right honourable Member is probably aware that there are very wide differences of opinion as to the extent of the evil complained of and the remedies to be applied. A departmental committee has been appointed by the Lord President for the purpose of providing useful and precise information on the subject.

The Registration of Dentist Companies.

Sir **JOHN BATTY TUKE** asked the President of the Board of Trade whether his attention had been called to the decision of the Master of the Rolls in the High Court of Justice in Ireland (Chancery Division) in the case of the Attorney-General *v.* Appleton and others; and whether the Board of Trade proposed to take any action in reference to that decision with a view to preventing in Great Britain such abuses of the Companies Acts as were disclosed in the course of the proceedings.—Mr. **GERALD BALFOUR** said: My attention has been called to the decision in the case of the Attorney-General *v.* Appleton. The Board of Trade is at the present moment taking the advice of the law officers of the Crown with regard to the instructions to be given by the Board of Trade to the registrars of joint stock companies in England, Scotland, and Ireland as to the registration of dentist companies.

The Medical Inspectors of the Local Government Board.

Mr. **CROOKS** asked the President of the Local Government Board whether the medical inspectors of that Board were permitted to accept appointments for pay outside their official duties.—Mr. **GRANT LAWSON**, who replied, said: A medical inspector is required to devote the whole of his official time to the duties of his office, but this is not intended to interfere with the manner in which he employs the rest of his time or his holidays.

TUESDAY, MARCH 14TH.

Medical Officer for Lewis.

Mr. **WEIR** asked the Lord Advocate whether he was aware that at a recent meeting of the Lewis district committee it was proposed that a medical officer of health should be appointed for the island of Lewis, and in the event of effect being given to the suggestion would arrangements be made for the new officer to be responsible to the Local Government Board direct and not to the medical officer of health of the county.—The **LORD ADVOCATE** said: The Board has no information of the meeting referred to and is at present awaiting the action of the district committee with which any arrangements regarding the appointment and its conditions primarily rest.

The Cotter Case.

Mr. **BOLAND** asked the Attorney-General for Ireland whether, with reference to the a[illegible] illage of Kenmare for an inquiry ir[illegible] the charges made [illegible] although he was [illegible] could be taken t[illegible] seeing that the [illegible] through the actic[illegible] that full inquiry [illegible] Mr. **ATKINSON** said: I stated in answer to the honourable Member's previous question of Thursday last that upon the information before the Local Government Board the reverend gentleman had not contravened the law. The Board is not aware that there are any grounds for the statement in the second part of the question. No cases of fever have been reported recently from this district other than that of the man Cotter.

Temporary Medical Officers to Irish Prisons.

Mr. **DILLON** asked the Chief Secretary for Ireland on what grounds the practice had been adopted in recent years of appointing temporary medical officers to Irish prisons instead of appointing permanent medical officers as was formerly the practice.—Mr. **ATKINSON**, who replied, said: The arrangement referred to has been adopted in the Irish prison service in order to assimilate the system to that previously existing in the Scotch service. The question of pensions is not affected as these officers did not devote their whole time to the service before the introduction of the change and consequently were not eligible for pensions.

Evasions of the Medical and the Dental Acts.

Sir **JOHN BATTY TUKE** asked the Home Secretary whether he was aware that evasions of the Medical Acts and the Dental Acts to the detriment of the public had been effected under the provisions of the Companies Acts; and, if so, whether he proposed to initiate legislation to preclude the possibility of such evasions being effected in future.—Mr **AKERS DOUGLAS** said: I am aware of the cases, recently before the courts, to which the honourable Member refers. I am not in a position to make any statement as to legislation, but I may say that the Lord President of the Council has been in communication with the General Medical Council and the Board of Trade on the subject of the companies carrying on business as medical men and dentists; and the Board of Trade is, I understand, obtaining the opinion of the law officers of the Crown on the question of the registration of such companies under the Companies Acts.

WESTON-SUPER-MARE HOSPITAL—House Surgeon, unmarried. Salary £100per annum, with board and residence.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Assistant House Physician for six months. Honorarium at rate of £75 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

DALY.—On March 13th, at Upper Clapton-road, N.E., the wife of Frederick J. P. Daly, M.R.C.S., L.R.C.P., of a daughter.

KENDALL.—On March 6th, at Chiddingfold, Surrey, the wife of Nicholas Fletcher Kendall, M.R.C.S. Eng., L.R.C.P. Lond., prematurely of a daughter, stillborn.

NASH.—On March 11th, at Clavering House, Bedford, the wife of W. Gifford Nash, F.R.C.S., of a daughter.

WALLACE.—On March 11th, at Battersea-rise, S.W., the wife of J. B. Wallace, M.B., of a daughter.

MARRIAGES.

CARVER—MACKAY.—On March 2nd, at St. John's Episcopal Church, Edinburgh, by the Rev. C. A. H. Going, B.A., Arthur Edmund Carver, M.D., Torquay, son of the late Edmund Carver, M.D., Cambridge, to Clare Patricia, daughter of the late Captain J. S. Mackay, 42nd Highlanders.

WALKER—GOADBY.—On March 9th, at St. Marylebone, by the Rev. W. Perowne Holmes, vicar of St. Peter's, Leicester, assisted by Canon Barker, Robert Alexander Walker, B.A., M.B. Cantab, third son of Thomas James Walker, M.D., J.P., of Peterborough, to Ethel Ernestine, youngest daughter of Major Goadby (Inspect. Ret. Army Schools), of Staidburn, Lancashire.

DEATHS.

ALLEN.—On March 7th, J. Allen, M.R.C.S., L.S.A., Grosvenor Lodge Ripley, Derby, aged 91 years.

SPENCE.—At Rio Janeiro, c[illegible] Spence, M.B., Ch.B. Edin., eldest s[illegible] Burntisland, aged 27.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE NEED OF DISTINCTIVE BOTTLES FOR POISONS.

A VERY sad case of accidental poisoning investigated at an inquest at Paddington on March 7th illustrated the need for enforcing the use for poisonous solutions of a bottle so distinctive in shape as to be incapable of being mistaken by anyone retaining his ordinary senses. The deceased, a young officer in the army, was suffering from blood poisoning and was being nursed by his wife without other assistance. He had taken one dose of a sleeping draught prescribed by his medical attendant and his wife, before lying down to rest on the sofa in his room, placed ready for him, as she thought, a second dose of the same medicine. There was, however, at the same time on the table a bottle containing carbolic acid and it was from this that the unfortunate lady filled her husband's glass without noticing her mistake. The patient awoke in the night and drank the carbolic acid with the result that although he roused his wife immediately and the medical man was summoned he died shortly after. A juror at the conclusion of the inquest, which resulted in a verdict of death from misadventure, aptly drew attention to the possibility of preventing such cases by suitable legislative provision That errors frequently occur with a drug of so distinctive an odour as carbolic acid proves that the peculiar bottle or stopper to be adopted should be one which would practically compel the most tired patient or nurse to observe it and it need hardly be said that such contrivances exist, one at least being referred to in another column. Unless, however, their use is made compulsory they are not likely to become universal owing to the possible slight increase in expense, and if not used on all occasions they will fail to be employed precisely in those households from which professional nursing is absent.

A QUEER KIND OF DRAUGHT.

To the Editors of THE LANCET.

SIRS,—The note of Mr. I. George in your last issue recording the use of placental blood by the mother as a draught after childbirth is interesting. In these days of organo-therapeutics it must have occurred to many, on witnessing the devouring of the placenta and decidua by the female of one of the lower animals that possibly nature prompts the act because of some therapeutic virtue in the placental tissue and fluids. It would be interesting to know whether any such custom has been observed among savage races and whether it is commonly practised in the country from which Mr. George's patient came.

I am, Sirs, yours faithfully,

March 15th, 1905. RUSTICUS

THE HISTORY AND ACTIVE CONSTITUENTS OF PAREIRA BRAVA.

IN suggesting an improved formula for the preparation of the liquid extract of pareira based on percolation with a mixture of alcohol, glycerine, and water, Professor H. G. Greenish gives some valuable details as to its constituents. Hanbury ("Science Papers," p. 382) mentions that the drug was first brought to Europe by the Portuguese in the seventeenth century and attracted general attention, being considered to possess extraordinary properties as a diuretic and lithontriptic. In Brazil it is still held in the highest esteem but much of its original reputation in this country has been lost, due probably in part to the more or less general substitution during the last 50 years of less active roots for the genuine pareira. At the present time t [illegible] tomentosum, is [illegible] in 1836, chief [illegible] It contains an unusual amount of fat and the alkaloid beberine to the extent of, perhaps, 4 to 5 per cent. The astringency of liquid preparations of pareira points to the probable presence of tannin. There is some danger in the present day when new remedies, mostly products of the chemical laboratory, are produced in such multitudes and highly extolled during their usually brief life that remedial agents of vegetable origin which have stood the test of time should be forgotten, owing mainly to the fact that there is nobody to call attention to their virtues as in the case of the newer remedies. In the present case it is possible that had the genuine drug been procurable during the last century it would not so readily have fallen into disuse. To show the high opinion originally held of it the following brief extract from Hanbury's "Science Papers" may prove of interest. In 1710 the French Academy requested G [illegible] pharmacy in the College [illegible] ira and among physicians [illegible] oung man, was consulted by Louis XIV. in his last days. Helvetius gave strong testimony in its favour. Both Geoffrey and Helvetius were correspondents of Sir Hans Sloane, that diligent promoter of science whose immense collection gave origin to the British Museum Among the Sloane MSS was found a letter from Helvetius to an ambassador at the court of George I., a portion of which is extremely interesting:—"I am extreamly pleased that you have apply'd yorself to me for my advice about the use of *Pareira Brava* .... because I can give you a very good account of it haveing been one of the first that introduced it in France. I have made abundance of lucky experiments about it......... wherefore I assure you, you can do nothing better than to make tryall of it. .... 'Tis called in Brazil the Universal Medicine and made use of there in all kinds of distempers. A Capuchin monk who came from thence told me he could not give it a greater character than by assuring me that in all their voyages they carried the gospell in one pockett and the *Pareira Brava* in another......"

BEARING REINS.

WE have received the report for the year 1904 of the Anti-Bearing Rein Association which has for its [illegible] gag bearing rein. We are aware th [illegible] rein may be necessary, at all events [illegible] that for cart horses it is not only unnecessary but harmful. The appliance is, we think, absolutely unknown in the case of omnibus horses and it is certainly more rarely to be seen than formerly upon horses used for other heavy loads. The great offenders are, as a rule, the upper classes and we frequently notice carriages standing in the streets, the horses of which are reined up so tightly as to be a disgrace. Even if a coachman is incapable of driving them without a bearing rein there is no reason why he should not let them "have their heads" while waiting. The gag bearing rein is false from a mechanical point of view and no lover of the horse can like to see the poor animal with its head kept in a ridiculously artificial position.

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to acknowledge the receipt of the following additional contributions?

CONCISENESS AND CONSUMPTION.

[illegible] wit, as Polonius reminded us, [illegible] displayed some soul which [illegible] panies have no souls. The [illegible] sengers not to spit in their [illegible] wo or three years constituted a progressive study in brevity. In December, 1902, a notice was [illegible] placed in a neat frame and hung [illegible]

vehicle, railway station, or other public resort. J. F. S. Gooday, General Manager, December, 1902."

Subsequently in the newer carriages another notice, consisting of a thin metal plate with a white ground and large dark blue letters, appeared. Two copies of this notice were placed in every compartment. This notice, which measured 8½ × 4½ inches and was fastened up with a dozen tacks, said: "Prevention of Consumption. Please do not spit" This was an exhortation. Since then another metal notice has appeared stating: "Prevention of Consumption. Do not spit." This is a command This brevity is a contrast to a notice placed inside some omnibuses in London as follows:—

> "London County Council. The London County Council hereby gives notice that, in pursuance of its powers under the Municipal Corporation Act, 1882, and the Local Government Act, 1888, it has made the following by-law for the good rule and government of the county of London and that the said by-law is now in force. *Spitting.*—No person shall spit on the floor, side, or wall of any public carriage, or of any public hall, public waiting-room, or place of public entertainment, whether admission thereto be obtained upon payment or not. Any person who shall offend against this by-law shall be liable for each offence to a fine not exceeding 40s. G. L. Gomme, clerk of the council, Spring gardens, S.W., July 10th, 1903."

This notice, when we saw it, was stuck on the roof inside the omnibus in such a way that in order to read it it would have been necessary to lie along the seat, so that it has probably not had much practical effect.

TUBERCULOSIS IN MEAT NOT DETECTED AT THE CENTRAL MEAT MARKET.

IN a recent case at the Marlborough street police-court a sanitary inspector gave evidence that in passing the shop of the defendants, a firm of provision dealers in Soho, he noticed that one of several pigs' heads exposed for sale was badly affected with tuberculosis. The defence raised was that the business carried on was of a high-class and respectable character and that the tuberculosis in the pig, the carcass of which had been disposed of already but of which the head remained, was of so slight a character that it had escaped the [illegible] the inspector at the Central Meat Market, of the dealer, [illegible] and of the defendants themselves. How the evidence which was called in support of this was reconciled with the obviousness of the disease to the passing inspector does not appear from the report before us. Mr. Kennedy said that great want of care had been shown and that as was usual in such cases, whatever examination there had been at the Central Meat Market or elsewhere had proved perfectly useless. Dr. F. J. Allan, medical officer of health of the City of Westminster, had stated in his evidence that if in the process of cooking the meat was exposed to a sufficiently high temperature the danger arising from eating tuberculous meat might be removed but that the products of the disease would remain. The argument that such meat is wholesome food *is a common line for the defence to take, as naturally* the medical officer of health in many cases where infected foodstuffs are concerned does not deny that steps may be taken to render them more or less innocuous. Mr. Kennedy, however, refused to adopt the suggestion. He said in plain terms that the sale of such unfit food as the pig's head in question was a very great danger to the public and that he refused to believe in tuberculous meat being made good to eat by cooking. He imposed a fine of £20 with £5 costs.

A "LOCK-AND-KEY" POISON BOTTLE.

THE reports in the press recently regarding a case of accidental poisoning, in which carbolic acid was administered in place of medicine, have led Messrs. Thomas Christy and Co. to introduce a "lock and-key" bottle which they consider will in the future prevent mistakes of this nature occurring. They propose to supply this "lock-and-key" bottle containing the usual quality of carbolic acid used for disinfecting purposes at the same price as commonly charged to the public in any ordinary bottle, and also to supply empty poison bottles with a nickel-plated patent automatic lock and key for locking up all poisons.

A SLANDER CASE.

AT the Durham winter assizes, before the Hon. Mr. Justice Bigham, the action brought by Dr. Harold E. Gamlen of West Hartlepool against Dr. John Hedley of Middlesbrough for slander was settled upon terms, the defendant having agreed to pay £50 damages and costs. Mr. Ivor Johnson, who appeared for the defence, said that his client made the statement complained of under a misunderstanding as to the facts of a case concerning the use of Roentgen rays in a case of phthisis under the treatment of the plaintiff and desired to withdraw the whole of the statements made and further to express his regret for having made them. Dr. Hedley wished this statement to be made in order that there should be no mistake about the withdrawal.

MORTALITY AT SEA.

AN official American report on mortality at sea suggests that travelling by ships is much more safe than travelling on railroads. The annual average of lives lost during the last 25 years is 1613, while in 1903 the total number of persons lost was 624, of whom 599 were sailors and 25 were passengers. Of the lost two had been sailing safely for 60 years, five for more than 40 years, and 21 for over 20 years. There were 5660 lives saved along the British coasts, 235 by the rocket apparatus, 489 by lifeboats, 205 were saved by coastguards, 578 were rescued by passing ships, and 1100 reached safety in the boats of their own ships.

DISINFECTION OF CONFESSIONALS.

THE Board of Health of Mexico is composed of thoroughly trained sanitarians. Recently that board recommended to the Government the importance of requiring the disinfection of confessionals as a measure for the prevention of the spread of contagious diseases. Acting on this recommendation, the Government has issued an order for the disinfection of confessionals in all the churches of that capital city daily. Priests in charge of churches who neglect the order will be fined and imprisoned. A similar order has been issued in the city of Guadalajaro and it is the intention to put it into effect throughout the republic.

"THE OPEN WINDOW."

ON March 3rd Dr. Harold Scurfield, medical officer of health of Sheffield, delivered a lecture at University College Hall in that city on the subject of the Open Window. After a recapitulation of the manifold dangers to health caused by the rebreathing of air and a demonstration of the necessity of frequently renewing the atmosphere of crowded rooms, he said that those who had to spend the greater part of the day indoors could compensate for this and obtain a continuous supply of fresh air at night by keeping the bedroom window open. He advocated letting a baby sleep in his cot with the window wide open night and day all the year round, provided that his body was kept warm. He had never heard of anyone adopting the open bedroom window and giving it up; the practice invariably gave a greater sense of physical fitness in the morning and a much lessened liability to catch cold.

We presume that there is no substantial difference of opinion within the medical profession as to the desirability of free ventilation, but in strange contrast with the foregoing we have received a letter dated from Brighton on March 5th inquiring "whether one needs to inhale oxygen during sleep." Our correspondent, whose name does not appear in the Medical Directory or Register, and who can hardly be either a medical man or a chemist, then proceeds to argue that if oxygen is not necessary during sleep "it is a good reason not to risk taking cold by open windows."

PAIN AFTER EXTRACTION OF TEETH.

To the Editors of THE LANCET.

SIRS,—I noticed in THE LANCET of March 11th, p. 686, a reply to "R. H." regarding pain after extraction. Several cases quite recently have come under my notice for treatment where continuous gumboils have been present previous to extraction of teeth, pain after which is bound to follow. It appears to last usually for about six days if not treated. The treatment which I find very effectual is to syringe the socket well out with hydrogen peroxide; then dry and apply equal parts of tincture of aconite, iodine, and belladonna, both in the socket *and around the gums in the immediate neighbourhood.* Relief is obtained within 24 hours.—I am, Sirs, yours faithfully,

Sherborne, Dorset, March 13th, 1905. F. VOSPER, L.D.S.

LIQUID POISONS.

Sir Thomas Dewar, M.P., is credited with the intention of introducing into the House of Commons a Bill rendering it illegal to sell liquid poisons in other than specially constructed bottles. It will be interesting to see what substances the introducer of the Bill defines as liquid poisons. Nearly all the alcohols are poisons and some are very poisonous and before now the drinking of a bottle of whisky has brought about death very rapidly.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index *to* Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; *copies only* should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

The Milroy Lectures
ON
INDUSTRIAL ANTHRAX.

Delivered before the Royal College of Physicians of London on March 7th, 9th, and 14th, 1905,

BY T. M. LEGGE, M.D. OXON., D.P.H. CANTAB.,
HIS MAJESTY'S MEDICAL INSPECTOR OF FACTORIES.

LECTURE II.[1]

Delivered on March 9th.

MR. PRESIDENT AND GENTLEMEN,—The treatment of anthrax has been conducted on three lines. The first is based on the fact that man is naturally possessed of a considerable degree of resistance to the disease, as spontaneous recovery from external anthrax is not infrequent. Treatment has, therefore, been conducted on expectant lines only. Secondly, and by far the commonest method, is removal or destruction of the pustule in the belief that the process is at first a local one, the bacilli developing at the seat of infection and only after lapse of time causing serious and it may be fatal effects either by intoxication or by a more widespread distribution of bacilli in the body. I include under this head such methods as excision, cauterisation, and injection into the tissues round the pustule of 5 per cent. carbolic acid, as they all have for their object either the direct destruction of the bacilli or the setting up of a barrier against further extension outwards from the central nidus. Thirdly, following on the successful results obtained in the treatment of certain infective diseases by inoculation with the serum of immunised animals, similar success has been claimed in the case of external anthrax also and, in Italy and South America notably, this method of treatment is coming more and more into practice. The fact that external anthrax is so frequently the subject of spontaneous recovery makes it difficult to compare the respective merits of one and another method of treatment when the only criterion taken is the proportion of deaths to the number attacked. But in the case of external anthrax there are other means of comparison which do not obtain equally in other diseases when this the chief is left out of account, namely—(1) the relative amount of scarring or of deformity left; (2) the applicability of the form of treatment to the differing types assumed by the disease and the stage which it may have reached; and (3) the length of time which elapses from the beginning of the treatment to resumption of employment. All these are fundamentally important in judging of efficacy and the third especially is of moment where industrial considerations enter.

Müller[2] bases a series of articles on the success attending 13 consecutive cases treated intentionally in Jena by the most conservative of methods—namely, rest, fixation, and elevation of the part affected, stimulating diet, and the local application of grey ointment. Ramstedt[3] from the same hospital more recently has adduced other seven consecutive cases (one a very severe one of anthrax of the tongue) in which nothing but the same expectant treatment was pursued. And, similarly, Fr. Schultze[4] of Bonn cites also a case of extremely severe malignant pustule of the cheek with extensive œdema of the eyelid, neck, and chest, so extensive as to suggest the gravest prognosis, which recovered (after a plastic operation on the eyelid) without operative treatment on account of the situation of the pustule. Muller's view is that the bacilli multiply slowly at the point of inoculation and that the œdema set up is due to toxins liberated by them. In itself this œdema up to a certain point is to be regarded as a healing process in that it is [illegible] of the bacilli already present and

development. The fact that in the blood and then only within a very short period prior to death shows, he thinks, that the blood is not readily infected. Unless the blood-vessels, therefore, are cut through the bacilli will not enter the blood stream except by the devious path of the lymphatic vessels and in the lymphatic glands the bacilli meet with obstruction and are held back. He assumes that generalisation of the infective organisms can only occur after the cells at the point of local infection have been weakened either by actual struggle with the bacilli or by the action of toxins and effort therefore should be directed to maintain the cells at the point of entry in such a state as to prevent best the further spread of the bacilli. Hence the reason for the conservative treatment. It is possible to deal with 11 of the 13 cases he describes, the data in two being insufficient for the purpose. Several were, he says, extremely severe but in all the temperature had sunk to normal and the œdema had considerably diminished within a few days of the date of commencing treatment. The duration of treatment varied from three to 45 days (so long a period in one case being necessary on account of necrosis of both upper and lower eyelids), the average duration being 16 days. But in seven of the 11 it is definitely stated that further attendance in the out-patient department was necessary—in one case for considerable loss of the skin of the arm. He regards as almost a crucial experiment the occurrence of death in the fourteenth case where incisions had been made into a malignant pustule which up to then had been doing well, with the result that after 12 hours the inflammation had extended widely and death ensued in 55 hours. The cases are too few to draw the sweeping conclusion Muller does but they are instructive in emphasising the difficulty in sifting the evidence of different methods of treatment. His view that obstacle is placed in the way of generalisation of anthrax by the lymphatic glands is supported by the experiments of Wyssokowitch[5] who found in one case of anthracæmia in man that he could cultivate 52 colonies of anthrax bacilli from a drop of blood from the finger, but similar cultivations from the vesicles, superficial and deep portions of the excised pustule, remained sterile. Following this observation up by injection of bacilli into rabbits in the region of the foot and watching the length of time which elapsed before the different glands and the blood became infected he concluded that the bacilli passed from the primary centre in the subcutaneous tissue into the blood chiefly through the lymph glands, which act as stations and hold up the bacilli until these grow through the glands and pass into the efferent lymph vessels. But seeing that as a consequence of the necrotic process many small veins must become thrombosed and be the seat of development of bacilli Müller gives no sufficient reason why these bacilli should not become detached and pass into the blood stream as readily as they would do were the blood-vessels cut through.

In the first lecture I showed that the mortality of the disease generally was at least 25 per cent. For cases treated under favourable conditions this figure is too high and by this is to be understood primarily excision not later than the fourth day after the initial symptoms have shown themselves. Unless the persons affected have knowledge of the nature of the disease or apply for treatment to a hospital the absence of pain and of constitutional disturbance often causes the lesion to be unheeded. That the general high death-rate is due to ignorance of the symptoms and neglect in applying for early treatment is shown, I think, by study of hospital records in districts where the disease is well recognised. *Thus in the hide and skin warehouses round Tooley-street* [illegible] apply usually in good

f malignant pustule

were fatal—7·1 per

new's Hospital two were fatal, and of 39 treated between 1896 and 1904 in the Bradford Royal Infirmary there were six deaths, 15·4 per cent. Study of these records leaves no doubt on the mind that in early cases, and frequently also in advanced, as soon as the local centre of infection has been removed or destroyed there is usually a rapid fall in temperature, the œdema commences to disappear and menace to life is over, although several days may elapse before all glandular swelling has subsided. Fatal cases are those in which excision is practised late and in which the symptoms are, already severe on admission. This statement must be regarded as a general one only, because examination of the notes on 64 cases treated in St. Bartholomew's Hospital and Guy's Hospital shows that in ten œdema increased after excision and in a small number of the deaths in London hospitals generalisation of the disease followed so quickly after excision as to raise suspicion that they were connected. Surgical interference in external anthrax usually takes the form of free excision, dissecting out the pustule from the healthy tissues beneath, swabbing the wound out with pure carbolic acid, and allowing the wound to granulate up from the bottom. Frequently, also, or in substitution altogether of excision, into the subcutaneous tissue around the margins of the malignant pustule 5 per cent. carbolic acid is injected. At Guy's Hospital, based on the experience of Davies-Colley,[6] which again was based on that of Muskett in South Africa, in addition to excision powdered ipecacuanha is dusted on the wound and ipecacuanha in ten-grain does is given internally. Muskett[7] himself in 15 years treated 50 cases without fatal issue, using locally ipecacuanha mixed with water to the extent of a cream and did not practise excision. He believed the remedy was as much a specific for anthrax as quinine is for ague and mercury for syphilis. Davies-Colley did not feel justified in omitting excision and believed that internal administration of ipecacuanha was useful in acting specifically on the small black sloughs not infrequently found in the intestinal tract in fatal cases, the cause probably of the vomiting so frequently complained of. Washbourn found, too, that ipecacuanha has the power of destroying bacilli but not the spores of anthrax and in the body sporulation does not take place. Muskett cites only four of his 50 cases, all of them affecting the forearm, hand, or finger. The treatment initiated by Davies-Colley is still that carried out most frequently at Guy's Hospital. Russian surgeons[8] appear to have used largely injections of carbolic acid round the pustule. Scharnowski has treated in this manner 50 cases with 2 per cent. of deaths and their severity may be judged from the fact that 25 affected the face and neck. Cases are recorded where very large amounts of carbolic acid have been injected in cases of anthrax when the œdema has been extending without production of symptoms of carboluria. Such a case is reported in the *Guy's Hospital Gazette* of Oct. 8th, 1904. Country practitioners make frequent use of the caustic potash stick alone. Graef[9] describes 384 cases of malignant pustule treated thus by himself and two other physicians since 1856 with 20 deaths—5 per cent. Of his own 75 cases four were fatal and ten were eventually cured after more or less local necrosis (in one case amputation of the arm). In the remaining 61 within 24 hours of the cauterisation the symptoms diminished and the threatening anthrax pustule was converted into a harmless eschar. The situation in these was about equally distributed on the face and neck, on the one hand, and the upper extremity on the other. The eschar commenced to detach itself in from ten to 14 days and became finally detached in the third or fourth week. In the neighbourhood of the eye sometimes plastic operation was necessary. Failure by this method he attributes to delay in application for treatment. He considers that the favourable result of the expectant treatment as shown by Müller does not justify the omission of destruction of the local centre, as he believes by that means the generalisation of the disease can be prevented. Excision as a preliminary to the use of caustics is allowable but, in his opinion, quite unnecessary.

---

The great objection, however, to be urged against excision is that in some situations—as, for instance, on the eyelids—operative treatment is impracticable or, if practised, must inevitably lead to disfigurement and necessitate subsequent plastic operation or skin-grafting to repair the loss of tissue caused; indeed, it may be said that subsequent treatment of external anthrax after excision is more concerned with remedying the conditions thus produced than by concern for the disease itself. Further, there is the objection that in a few cases it may lead to generalisation. Examination shows that of 15 cases treated by excision at St. Bartholomew's Hospital the average stay in hospital was 20 days and that in not one is it stated the wound was quite healed at the time of discharge. Similarly in Guy's Hospital of 43 cases the average duration of treatment was 15·7 days; in the London Hospital of 38 cases, 16·1 days; and in the Bradford Royal Infirmary of 32 cases, 22·6 days. I draw no inference respecting the average duration of stay in one and another hospital, for this necessarily is dependent on the pressure there may be for beds, causing in some cases an earlier discharge to the out-patient department than in others.

In view of the importance of examining the method of treatment by anti-anthrax serum closely I have set down the details of all the published cases that I can find[10] without selection (see Table X.). All but two of the cases have been treated in Italy with Sclavo's serum. Those numbered 1 to 23 are consecutive cases treated by Dr. Lazzeretti[11] of Siena and 28 to 53 by Dr. Cicognani[12] of Santa Croce. Of the 67 cases 56 were treated by serum alone and in 11 this serum treatment was subsequent to other treatment which in ten cases had been excision or cauterisation or both. In 44 of the 56 treated with serum alone data are given precise enough for practical purposes to determine the time which elapsed from the commencement of treatment until complete recovery. In several instances it is the same as the time given for the separation of the eschar but many days before that stage has been reached the patient is to all intents and purposes quite well. Excluding the fatal cases, in every instance but one by the third day marked improvement, not only in the general symptoms but in arrest of the further development of the pustule and in diminution of the œdema, had taken place. Taking the time thus given or to be inferred in these 44 cases the average duration of treatment was eight days. In none was it more than 14 days. I can affirm, too, that in the 12 cases treated with serum alone in which the details are not precise enough to allow of the number of days being given the evidence all points to rapid healing, except in Nos. 24 and 33 where there was loss of tissue. The exact description, so far as it is given, of the final condition at the site of the pustule itself may be summarised as follows: No visible scar, 10; scar hardly visible, 5; slight scar, 10; completely recovered, 15; some loss of tissue in eyelid but function unimpaired, 1; and complete loss of the upper eyelid, 1; total, 42. The situation of the pustule in these cases is indication enough of their severity, the high proportion on the eyelid being especially noticeable. (Table XI.)

In the list are two fatal cases, Nos. 10 and 49. In the first the patient was the subject of malaria, was addicted to alcohol, and had had syphilis. The upper eyelid was affected with œdema extending rapidly over the face and chest and there was no necrotic patch to assist in the diagnosis. The condition was suspected to be diphtheria of the conjunctival mucous membrane and diphtheria antitoxin was injected. A day later some vesicles appeared on the eyebrow, on which date 20 cubic centimetres of the serum were administered. Improvement in the local and general conditions ensued shown by reduction in the œdema, subsidence of fever, and regained appetite. Four days later, improvement during that time having been continual, he was seized with a rigor, violent headache, vomiting, rise of temperature, and delirium, on which followed profound collapse, coma, and death. Post mortem there were found extensive submeningeal effusion and hæmorrhage in the substance of the brain. Anthrax bacilli were found in the submeningeal effusion. In the other case, also affecting the eyelid, serum treatment was delayed owing to the impossibility of obtaining it, so excision was practised. When the serum was obtained and injected intravenously immediate improvement took place. Two days later the œdema had diminished so much that the woman was able to see out of her eye, took her food well, and the pulse-rate dropped from 140 to 104. A few hours later she was seized with sudden collapse, cyanosis, and died. No post-mortem examination was held. Of the nine other cases treated with excision or cautery as well, in one there was complete necrosis of the upper and lower eyelid and in two others it is stated that after four days' treatment the local injury was the only concern, although one was of such exceptional gravity as to have received 200 cubic centimetres of the serum intravenously within 24 hours. In another case in which the bacilli were found in the blood and urine 190 cubic centimetres were administered in the course of seven days.

Particulars are given as to the amount of serum injected in each case. In the early days of the treatment the doses were comparatively small, no more than 20 or 30 cubic centimetres being given at the initial injection. In later cases the initial dose is generally 40 cubic centimetres and those who have experience of the treatment strongly advocate big initial doses. In 39 of the cases the initial dose sufficed. These cases, however, by no means exhaust the list of those in which serum treatment has been adopted. Sclavo[13] himself in 1903 reviewed the subject in a paper in which he tabulated all the cases known to have been treated by means of it in Italy whatever the stage of the disease. These totalled 164 with ten deaths—6·09 per cent. as compared with 24·1 per cent. for the whole of Italy. The facts stated by him he believes are very far from showing accurately the therapeutic value of the anti-anthrax serum. In the early days of a new treatment holding out a possible hope there is always temptation to use it in the most desperate cases. To two of the fatal cases I have referred already. In another, affecting the upper eyelid, the disease was not diagnosed until too late when the woman presented herself with a high temperature, very weak intermittent pulse, difficulty of respiration, and œdema of the face, the neck, and the chest. Death took place within nine hours of commencing treatment. In the fourth the pustule was situated on the neck with marked cyanosis from dyspnœa caused by the œdema. 25 cubic centimetres were injected with little hope of benefit and death followed within 20 hours. In the fifth the pustule was situated on the neck with œdema of the greater part of the thorax. Death took place within 11 hours of admission. 20 cubic centimetres only were injected. In the sixth no record was kept except that death took place within 30 hours of admission. In the seventh the pustule was on the neck with œdema rapidly extending to the thorax. Bacilli were found in the blood. There appears to have been no reaction to injection of 45 cubic centimetres on the first day and 30 cubic centimetres on the second. Of the eighth, particulars are not given except that the patient was admitted to the hospital in a serious condition, the victim of alcoholism and suffering from disease of the heart. The ninth had œdema of the neck and chest, and 20 cubic centimetres were injected. On the following day there was marked improvement. 20 cubic centimetres were again injected but death occurred suddenly on the morning of the next day with symptoms of hemiplegia.

Since July, 1904, serum treatment has been tried in England either alone or in connexion with excision in 12 cases of external anthrax. In one case of so-called malignant anthrax œdema also on the tenth day after the initial symptoms and when the patient was in a comatose condition 30 cubic centimetres were injected subcutaneously four hours before death at a time when bacilli were found present in the blood. In four of the 12 cases of external anthrax serum treatment alone without excision was adopted. The situation of the pustule in these cases was: (1) the malar eminence of the cheek; (2) the forehead; (3) the upper eyelid; and (4) the forearm. Cases 1 and 2 were treated at St. Bartholomew's Hospital.[14] An initial dose of 40 cubic centimetres sufficed in both cases to arrest further "development of vesicles or other indications of the necrotic process." There was increased œdema but this was associated with improvement in all other respects. In one of the cases no colonies of anthrax could be cultivated 19 hours after the serum had been injected although previously the fluid of the vesicles yielded abundant colonies. "Cultures were repeated on the third day again with negative result ...... only a few disintegrating bacilli were found, mostly enclosed in leucocytes." In both cases hardly any scar was left. Case 3 was treated by Dr. W. Mitchell of Bradford. The patient was a mill worker. Already by the second day both eyelids were closed with œdema, which extended to the clavicle on the left side, and the right upper and lower eyelids were dark coloured and appeared as if about to necrose. In four days 100 cubic centimetres were injected, 20 on the first, 50 on the second, 30 on the third, and ten on the fourth. By the fifth day the œdema had almost all disappeared except such as would readily be accounted for by the presence of a necrotic area on the left upper and lower eyelids. Although the local symptoms here were very severe the general condition of the patient remained good. Case 4 was treated at the Royal Infirmary, Bradford. The type of the disease was described as very malignant, with œdema rapidly extending to the shoulder. The patient received 140 cubic centimetres in the course of three days (30 cubic centimetres intravenously on the morning of the day of death). There appeared to be reaction at first in rise of temperature to 103·6° F. but the œdema continued to spread; he became insensible and the diagnosis of meningeal hæmorrhage between the pia mater and arachnoid was made by Dr. J. H. Bell. Post mortem the brain was found to be surrounded with blood between the pia mater and arachnoid and nowhere else.

Six of the eight cases in which excision was practised as well as serum administered (treated in Guy's Hospital, Bradford Infirmary, Kidderminster Infirmary,[15] and by Mr. E. G. Peck of Queensbury, Bradford) made rapid uninterrupted recovery. In the seventh, treated at the North Stafford Infirmary, excision of the pustule on the hand and incisions in the brawny œdema had been made on the twelfth day of the disease. Administration of serum was commenced 24 hours later when the patient was already in a comatose condition. Death took place 24 hours later, there having apparently been no reaction to the serum treatment (except in diminution of the œdema). In the eighth the pustule was situated on the neck with rapidly extending œdema. Two injections only of ten cubic centimetres at 12 hours interval were given. Death occurred within 30 hours of excision.

The claims which have been made as to the effect of serum treatment can be summarised by saying that: (1) even in very large doses it is innocuous; (2) it can be well borne even when introduced into the veins; (3) no case taken in an early stage or of moderate severity is fatal if treated with serum; (4) with the serum some cases are saved when the condition is most critical and prognosis almost hopeless; (5) when injected into the veins the serum quickly arrests the extension of the œdematous process so as to reduce notably the danger from suffocation which exists in many of the cases where the pustule is situated on the face or neck; (6) if used soon enough it reduces to a minimum the destruction of the tissues at the site of the pustule; (7) in some situations of the pustule, as the eyelid, serum treatment must be used in preference to any other as it alone can hold out hope of success without permanent injury; and to these may be added (8) that in internal anthrax it is the only treatment which holds out any hope of benefit. In almost all cases injection of the serum is followed by a rise in temperature often to over 105° F. and with it there is an improvement in the general condition of the patient. In the same way the necrotic process itself is to be regarded as a sign that the organism is making effort to resist the anthrax infection.

A few facts may emphasise the value and importance attached to the serum treatment in Italy. In Santa Croce,[16] a small town on the Arno of about 5000 inhabitants, are 36 tanneries employing 350 workers. Danger of anthrax is recognised as being practically limited to hides coming from the east and especially from China, so much so indeed that some manufacturers had ceased to use them. Anthrax among the workers had been frequent, of which the series of cases 28–53 in four years is sufficient evidence. Dr. Cicognani has adopted the serum treatment exclusively since 1899, having had experience that the other methods of treatment did not always prevent a fatal issue and when successful the sufferers could not resume their occupation until after a long period of convalescence. The workers now insist on having this treatment to the exclusion of every other and he states that the manufacturers are so certain of its efficacy that they hesitate no longer to use even Chinese hides. The workers, too, are now so willing to undergo treatment, since operative treatment is uncalled for, that they present themselves when there appears the

particular organism and antitoxic as regards the toxin contained in its substance.

The work of Wright and Douglas,[27] with its proof that the blood fluids by means of certain substances, "opsonins," contained in them modify bacteria in a manner which renders them a ready prey to the phagocytes, may be expected to throw light on the action of the anti-anthrax serum. The anthrax bacillus unfortunately, owing to thread formation, does not appear to lend itself well to the particular method of experiment employed by them—namely, averaging the number of bacteria ingested by a certain number of leucocytes—but in experiments on the opsonic power of human blood in its relation to the anthrax bacillus when unheated serum was used they say, "Although enumeration was impossible there was everywhere evidence of phagocytosis. In the few cases where the leucocytes had not ingested bacteria they were found to have extended themselves in a characteristic manner along the bacterial thread." Repeating the experiments with heated serum "there was practically no sign of phagocytosis." The presence of opsonins in quantity in the blood after inoculation of serum would account for the observation of Andrewes in the case already referred to in which no anthrax colonies could be cultivated 19 hours after injection of serum although their presence had previously been abundantly proved, such few disintegrating bacilli as were found being mostly inclosed in leucocytes.[28]

The Hunterian Lectures

ON

THE PHYSIOLOGY AND TREATMENT OF SURGICAL SHOCK AND COLLAPSE.

Delivered before the Royal College of Surgeons of England on March 6th, 8th, and 10th, 1905.

BY J. P. LOCKHART MUMMERY, M.B., B.C. CANTAB., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS OF ENGLAND; HONORARY SURGEON TO KING EDWARD VII.'S HOSPITAL, ETC.

LECTURE II.[1]

Delivered on March 8th.

ÆTIOLOGICAL FACTORS IN THE PRODUCTION OF SHOCK DURING OPERATIONS.

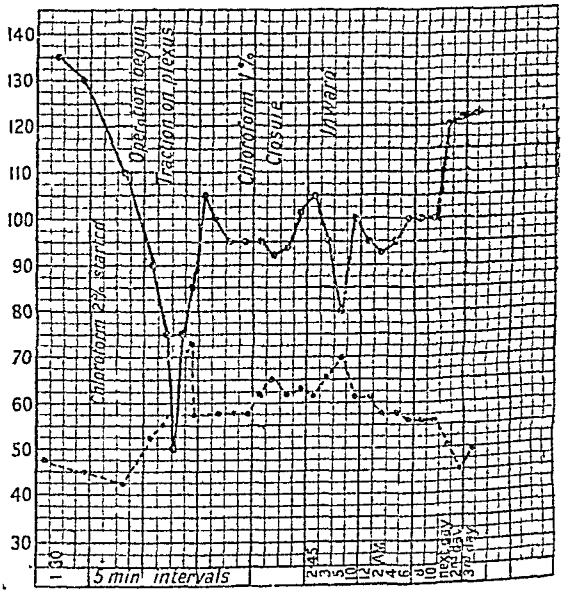
The relation between shock and the region operated upon.—As a general rule it may be stated that the degree of shock produced by an operation is dependent upon the amount of traumatism to the nerve elements of the part operated upon. Thus traction upon important nerves or injury to them will cause more shock than the same amount of interference with other tissues. I have observed that traction upon the brachial plexus during the process of clearing out the axilla in an amputation of the breast will cause a marked fall in blood pressure (see Fig. 5). It may be stated that the degree of shock caused by an operation is in direct proportion to the area of skin and muscle injured and the relative number of nerve endings in them. Thus crushing injuries of the feet or hands will cause more pronounced shock than amputation of the limbs high up. Crile has observed that in dogs crushing the paw will cause a greater fall in the blood pressure than section of the main nerves in the thigh. Injury to parts richly supplied with nerve endings, such as the genital organs, is very liable to cause shock. The area of wound surface exposed during an operation would also seem to be a factor in the production of shock. Crile states that in animals subjected to extensive removal of integument shock is induced with a rapidity proportional to the area exposed and its depth corresponds to the duration of exposure.

Of all injuries those such as burns and scalds which involve a large area are most frequently followed by shock. The shock produced by severe burns or scalds is due not so much to the severity of the injury as to the area of injured tissue and the number of nerve endings involved. Thus dangerous or fatal shock more frequently follows burns of the second and third degrees than those of the fourth and fifth degrees, because in the latter the nerve endings are destroyed, while in the former they are injured but can still send impulses to the nerve centres.

The first effect produced upon the blood pressure by injury to any part of the body richly supplied with nerve endings, such as the genital organs, the neck of the bladder, and the rectum, is a rise. Often a very marked rise in blood pressure occurs at first. If the injury is continued or is very severe this initial rise is either replaced by a fall in blood pressure or is followed by a fall. Thus in the operation for hæmorrhoids a very great rise in pressure almost invariably results from dilating the sphincter or from cutting away or ligaturing piles which involve the muco-cutaneous edge. Dilating the os uteri causes a similar result. Dilating an old urethral stricture with metal instruments caused at first a rise in the blood pressure, this rise being subsequently followed by a fall to a much lower level. Operations for fistula in ano when the sphincter is divided cause very irregular rises and falls in the blood pressure.

More severe and prolonged operations upon the rectum, such as excision for carcinoma, cause a fall in the blood pressure. In one case the pressure fell from 175 millimetres of mercury previously to operation to 110 millimetres of mercury at the end of the operation. In another case of excision of part of the rectum for a large papilloma the blood pressure fell from 150 to 115 millimetres. During an operation for the removal of cancerous glands from the neck in which the glands were found to be fixed to the carotid sheath and vagus the blood pressure fell from 155 to 110 in ten minutes while the glands were being exposed and dragged upon. During an amputation through the thigh for sarcoma of the knee in a man, aged 56 years, the blood pressure fell from 135 to 90. Prostatectomy in a patient, aged 60 years, caused at first a rise in the blood pressure from 190 millimetres of mercury to 245 and subsequently a fall to 100 millimetres of mercury (see Fig. 7). During an operation for excision of the shoulder-joint for an old fracture-dislocation in a woman, aged 58 years, where considerable difficulty was experienced in getting out the head of the bone, a fall in the blood pressure from 160 previously to operation to 95 was noticed (see Fig. 8).

FIG. 5.



Amputation of the breast with pectoral muscles and axillary glands in a woman aged 48 years. Chloroform was administered with a percentage inhaler, not more than 2 per cent. at any time. Traction on the brachial plexus led to sudden collapse, pallor, shallow respiration, and a great fall in blood pressure. There was a slight degree of shock present at the end of the operation.

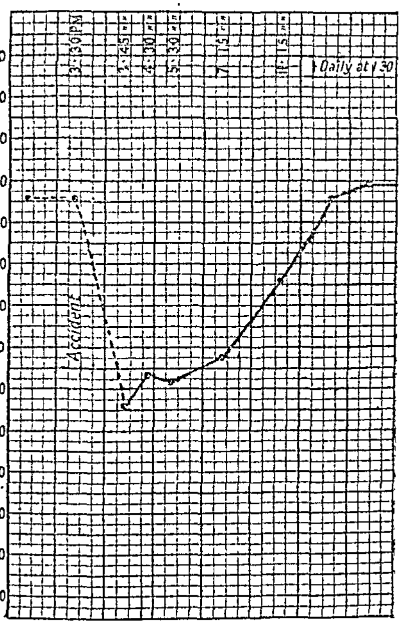
[1] Lecture I. was published in THE LANCET of March 18th, 1905, p. 696.

In operations upon the abdomen the degree of shock produced depends very much upon the area of peritoneum exposed and the duration of the exposure. Generally speaking, operations upon the abdomen are more liable to cause shock than operations upon other parts of the body. Operations upon the upper portions of the abdomen, such as the stomach, duodenum, &c., cause relatively more shock than operations in the lower parts near the pelvis. The shock seems to depend upon the injury to, or exposure of, the peritoneum. Any form of manipulation of the peritoneum, such as traction upon it, sponging, flushing with hot water, and even exposure to the air alone, causes a fall in blood pressure which, if the cause be continued, is progressive. Interference with the mucous membrane of the intestinal tract does not seem to affect the blood pressure. Operations such as colotomy and appendicectomy, where only a small portion of peritoneum is exposed, do not cause much alteration in blood pressure.

FIG. 6.



Moderate [illegible]

arm. [illegible]
24 hour [illegible]
previous to the accident.

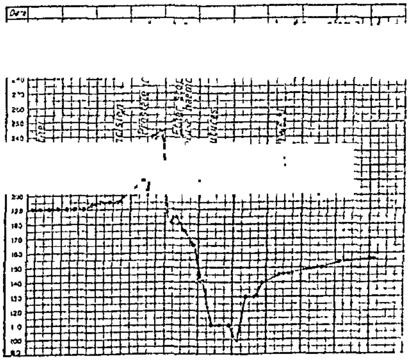
I have made a number of observations on the blood pressure during abdominal operations and the charts generally show well-marked but irregular rises in the blood pressure as the result of the different manipulations during the first stage of the operation. This stage varies [illegible] the nature of the operation and the [illegible] ome cases [illegible]. During [illegible] nal level though slight temporary rises in the blood pressure were observable as the result of manipulation; the general tendency, however, was towards a fall. The next and third stage, which was only seen in very severe operations, was marked by a steady and progressive fall in the blood pressure; any manipulation at this stage, such as would cause a rise in the pressure during the earlier stages, caused a fall which was often sudden, or if a rise in the pressure resulted, it was immediately followed by a fall to a much lower level. In operations upon the upper part of the abdomen such as the stomach and the gall-bladder the tendency was often towards a fall in the blood pressure almost from the commencement of the operation. During the operation of cholecystotomy in an elderly man I observed a fall in the blood pressure from 165 to 125 during the first 15 minutes of the operation. The application of hot sponges to the peritoneum or flushing the peritoneum with hot water usually caused a sudden rise in the blood pressure. In the later stages of the operation, however, it sometimes caused an equally sudden fall.

Turning the intestines out of the abdomen is in all cases followed by a sudden and often dangerous fall in the blood pressure. In one case I saw a patient who was suffering from shock become pulseless and die almost immediately after the intestines had been turned out of the abdomen to get at an obstruction in the colon. In a case of laporotomy for tuberculous peritonitis in a child Cushing observed a fall in the blood pressure from 112 to 70 result from partial evisceration; returning the bowels into the abdomen caused the pressure to rise at once to 90. Evisceration and extensive intra-abdominal manipulation, especially in the upper regions of the abdomen, are always followed by a very marked fall in the blood pressure. There is not sufficient evidence at present to say whether this fall in blood pressure is caused by a reflex effect upon the vaso-motor centres in the medulla as the result of sensory stimuli from the peritoneum or whether it is due to direct insult to the vaso-motor nerves in the splanchnic area. There is no doubt, however, that these procedures in the course of an abdominal operation are very apt to result in shock and may cause fatal collapse in a patient already suffering from that condition.

The influence of age upon the development of shock.—In elderly patients [illegible] observed, the [illegible] 150 and 170. [illegible] sclerosis. In s[illegible] point a little below the normal blood pressure for an ordinary adult may cause shock and in such a patient severe shock may be present with a recorded pressure of 90 or 100 millimetres of mercury. Shock seems to be developed more easily in elderly patients but so far as I have been able to ascertain the difference is not great. As one would expect, recovery from shock appears to be slow in elderly patients. It is noticeable that much greater variations in blood pressure occur during operations upon elderly patients than in young adults. This seems to show that the blood pressure is not under such complete control or, in other words, that with advancing age compensation for variations in the blood pressure tends to become imperfect.

Shock is always supposed to develop much more readily in children as the result of operation than in adults and shock is the chief risk of severe operations in children. Blood-pressure charts taken during operations upon children show that the pressure is very well sustained during the early stages of the operation but that these stages are much shorter in point of time. So that the terminal stage of exhaustion of the centres is reached much earlier in children

FIG. 7.

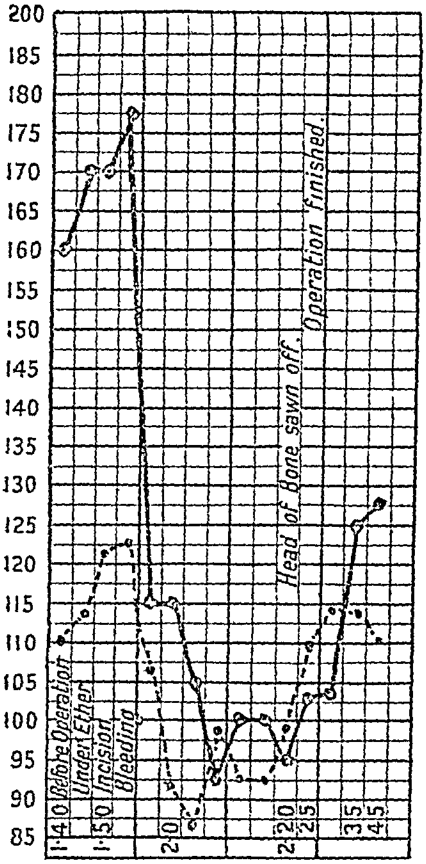


Prostatectomy in a man aged 60 years Slight shock and recovery. (Janeway.)

than in adults. The whole question in fact is one of time. Children have not any special liability to develop shock. And if the time which is occupied in performing the operation is reduced in proportion to the youth of the child I do not think that children are any more liable to develop shock as the result of an operation than adults.

The effect of the anæsthetic.—The influence of the anæsthetic upon the blood pressure during a long operation is very marked and the two anæsthetics in common use vary very widely in their effects upon the blood pressure. Ether anæsthesia causes a rise in the blood pressure in almost all cases. There is a marked rise in the blood pressure in the early stages of ether anæsthesia and the net result of all the investigations into the effect of ether anæsthesia upon the blood pressure shows that it tends to remain at its normal level or to be raised slightly throughout the whole period of ether anæsthesia, any fall in blood pressure which occurs during an operation being due to the steps of the operation and not due to the anæsthetic. Thus Cook and Briggs came to the conclusion that a fall in blood pressure never occurred during ether anæsthesia unless some cause apart from the anæsthetic was present. Blauel in 100 observations found a rise in blood pressure present throughout the whole period of ether anæsthesia in 79 per cent. and a fall in only 12 per cent., in most of which other causes were present. In my own series of charts of operations it seems that the effect of ether anæsthesia is towards a rise in the pressure.

FIG. 8.



Excision of shoulder for old fracture and dislocation in a woman, aged 58 years. Considerable bleeding and much traction necessary to get out the head of the bone. The high initial pressure is due to arterio-sclerosis.

With chloroform anæsthesia the results are almost the exact opposite of those with ether anæthesia. It has always been said by London surgeons that ether anæsthesia is safer in long operations and those where shock is anticipated than chloroform anæsthesia. This fact previously based upon clinical observation is proved beyond all shadow of doubt by blood-pressure records of operations. Chloroform anæsthesia is accompanied by a fall in blood pressure during the whole period of anæsthesia. The effect of chloroform upon the blood pressure is very striking indeed; a fall often to quite a considerable extent almost always follows its administration. In fact, it seems as if chloroform has a direct toxic influence upon the vaso-motor centres and produces by its action upon these centres a fall in blood pressure from lowered peripheral resistances.

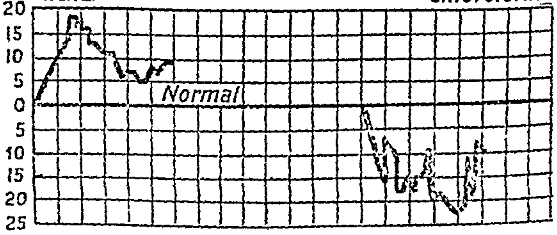
My own observations upon blood pressure, which have been carried out entirely with the object of elucidating the subject of shock, have incidentally led me to the belief that many, if not all, of the accidents which occur with chloroform are due to the effects of that drug *not* upon the respiratory centre and not to the effect upon the cardiac centres but are directly due to the toxic effects of the drug upon the vaso-motor centres. It so happened that on one occasion I was taking readings of the blood pressure of a patient who was being operated upon for piles. The patient struggled during the early stages of the operation and the anæsthetist changed from ether to chloroform. The patient was breathing very deeply at the time and the result no doubt was that a considerable overdose of chloroform was given. Four minutes later the operation was finished and the anæsthetic was stopped. Beyond the fact that the patient was deeply anæsthetised there were no alarming symptoms, but I found that the blood pressure had fallen to an alarming extent and during the following two minutes the respirations stopped and the patient became pulseless. Vigorous artificial respiration happily restored the patient. In this case I was able to observe that the blood pressure had fallen to a dangerous level some time before symptoms of chloroform poisoning developed.

The effects of chloroform in lowering the blood pressure have been demonstrated by Crile, by Duploy and Haillion, and by Remedi upon animals, and upon man by Blauel, Kapsammer, and numerous other observers. Blauel found a marked fall in blood pressure in 69 per cent. of cases of chloroform anæsthesia. Blauel's chart shows the relative results of the two anæsthetics in tabular form. (See Fig. 9.) My own observations seem to show that shock develops much sooner in those operations where chloroform anæsthesia is used than in those where it is not used.

There can, I think, be no doubt that shock is more likely to develop and will develop more rapidly in operations performed under chloroform anæsthesia than in operations performed under ether. I believe, moreover, that the so-called gas-ether-chloroform sequence for long and dangerous operations is a mistake, as it results in chloroform being administered at just that period of the operation when the maintenance of the blood pressure is all important. In operations upon the stomach and other abdominal operations where there are serious objections to ether anæsthesia on account of its liability to cause vomiting and to set up lung complications the C.E. mixture is certainly the best substitute from the point of view of subsequent shock. Blood-pressure charts taken during such operations where the C.E. mixture has been used show that the blood pressure is well sustained.

Time.—This has a most important bearing upon the development of shock. If one examines the blood-pressure charts of patients during an operation the effect of time upon the fall in blood pressure is unmistakeable. The longer the operation the greater the fall; this applies to every kind of operation and in the more severe operations the element of time can be seen to be a very important factor.

FIG. 9.



Blauel's chart of results upon the blood pressure caused by anæsthetic narcosis for at least 50 minutes, calculated from 25 cases of ether and 18 of chloroform anæsthesia, all the subjects being over 20 years of age.

In the pre-anæsthetic days speed in operating was of extreme importance and the great surgeons of those days depended very largely upon their ability to operate rapidly for the success of their operations. After the general use of anæsthetics and the development of aseptic methods of operating the pendulum swung the other way and great care and minute attention to detail were considered of more importance than the speed of an operator. Now the pendulum is swinging back and we are realising that speed is still of importance. In the more severe operations in which shock has to be reckoned with, every minute during which the operation is prolonged increases the risk of shock. We see this particularly in children; they will not stand prolonged operations, though they stand even severe operations well and recover rapidly if the operation is quickly performed.

It is a well-known fact that symptoms of shock frequently do not show themselves until some time after an operation; often not for several hours after the patient has been taken back to bed. This form of shock which develops some hours after an operation is frequently seen in children. This phenomenon can be seen very well if a chart of the blood pressure is kept. The chart usually shows that the blood pressure is dangerously low at the end of the operation, though there may be no symptoms of shock. The pressure, however, instead of rising again remains at the low level or slowly falls still lower. When the patient is in this condition the least thing may be sufficient to cause a dangerous or fatal fall in the blood pressure. In this exhausted condition of the nervous system afferent nerve impulses of any sort tend to lower the blood pressure instead of raising it, and acting in this way the pain and restlessness which so frequently accompany the post-operative period of returning consciousness probably act as the exciting cause of the ultimate breakdown of the vaso-motor system.

Cushing has pointed out that the blood-pressure charts clearly show that the weak pulse which is seen under these conditions is best stimulated by small doses of morphine to stop the inflowing sensory impulses. Blood-pressure charts are of considerable value, as they enable us to anticipate this condition of post-operative shock and we can thus by the adoption of suitable measures often avoid its development.

The condition of the patient prior to operation.—This has always been recognised as an important factor in the causation of shock. The physical factors in the patient's condition which are the most important as tending towards the production of shock are conditions in which the activity of the nerve centres tends to be lowered. Thus patients who are recovering from illness or who are at the time of operation suffering from illness are much more liable to develop shock than those in vigorous health. We see this in patients operated upon for perforation in typhoid fever.

It is often very difficult to estimate the condition of a patient with regard to his power of standing severe operative procedure. Thus often a weakly-looking individual who looks as if he would not stand a severe operation well stands it quite well and *vice versâ*. I think this is accounted for by the fact that a person of poor physique who leads a strenuous life has often much more highly developed nerve centres than one of robust physique who leads a life of ease and indolence which makes but slight calls upon his nerve centres for great or sudden activity. The mental condition of a patient prior to operation has a considerable influence upon the development of shock, though it is difficult to see why this should be so on physiological grounds. There is no doubt, however, that patients who dread an operation and who are in a state of considerable mental anxiety before the anæsthetic is administered are more liable, other things being equal, to develop shock than those whose mental equilibrium is undisturbed.

Conditions which accompany shock.—As has already been pointed out in considering the physiology of shock, it is only to be expected that in severe conditions of shock where the blood pressure has fallen to a level at which the circulation is inefficient there must be a profound change in the functional activity of every organ and tissue in the body.

Temperature.—Several observers have attempted to prove that some of these conditions which accompany shock are the cause and not the result of that state. Thus Kinnaman, arguing from experiments upon dogs, says that the fall in bodily temperature which accompanies shock is the cause and not the result of the fall in blood pressure. He argues that shock is always accompanied by a fall in body temperature and that in shock a rise in body temperature is followed by a rise in blood pressure and amelioration of symptoms. I think, however, that it is much more reasonable to consider the fall in body temperature as a secondary condition to the fall in blood pressure.

Kinnaman has demonstrated by a series of careful experiments that if an animal is killed by prolonged exposure of the intestines the body temperature (as ascertained by a thermometer in the rectum) falls continuously till the death of the animal. This fall in temperature occurs together with the fall in blood pressure and he found that both the temperature and the blood pressure are raised by immersion in a bath a few degrees warmer than the animal. Immersion of the animal in water will, however, raise the blood pressure quite independently of the temperature by increasing the outside pressure. He also failed in his experiments to take into account the alteration in the specific gravity of the blood which follows from exposure of the intestines and which must be a very important factor in such experiments.

There can be no doubt that in cases where shock results from exposure of the intestines the fall in body temperature which must result from exposure of so large an area of peritoneum is an important factor in hastening a fatal issue though it does not follow that it has any direct influence in the causation of the condition we know as shock. These experiments clearly show that a rapid fall of temperature which is steadily progressive follows exposure of the peritoneum to the air and that this lowering of the body temperature helps to hasten the subsequent complete breakdown of the circulation.

The lowering of the body temperature which occurs in cases of shock resulting from operations or injuries in which the peritoneum is *not* exposed is probably entirely secondary to the deficient circulation resulting from the fall in blood pressure, except perhaps in cases where a large wound area is exposed.

Secretions.—In conditions of shock all the secretions of the body are either arrested or markedly decreased. Many of the secreting glands, notably the salivary glands, depend for their secretive activity upon a high local pressure in their capillaries and if this pressure fails secretion is arrested. The intense thirst of patients suffering from shock has probably two causes: first, dryness of the mouth resulting from arrested secretion in the salivary glands; and, secondly, a physiological call for fluid by the tissues. Partial anuria always occurs in shock and complete anuria is not uncommon. This is accounted for by the lowered blood pressure.

Diabetes.—It is a well-known fact that diabetes may follow shock, whether the shock be produced by severe injury or by operation. The diabetes often is not noticed for some weeks after the injury, though glycosuria has often been noticed within a few hours. It is certainly not yet proved that diabetes occurring under these conditions has any direct relationship to shock. The association of circumstances would appear to indicate some connexion, but until further evidence is forthcoming I must be content with merely stating the fact. Mark R. Taylor reports a case of a strong healthy labourer who developed symptoms of diabetes 16 days after an operation for strangulated hernia.

Consciousness.—In syncope loss of consciousness is the rule but in shock there is usually no impairment of consciousness. In collapse impaired consciousness may occur but this depends entirely upon the rapidity of the fall in blood pressure. If the blood pressure falls slowly and there is no sudden alteration in the intracranial pressure consciousness is not altered, but if the fall is sudden unconsciousness and often other cerebral effects are seen.

TREATMENT OF SHOCK AND COLLAPSE.

The percentage of deaths from shock following major operations.—In order to try to ascertain the percentage of deaths from shock following the major operations of surgery at the present day I have analysed the cause of death in 200 cases at one of the large London hospitals. For this purpose I took 200 consecutive cases of death following upon an operation and analysed the cause of death as accurately as possible. It was not possible in many cases to be quite certain that the [illegible] died from shock, but I assumed shock to have be[illegible] I have little doubt that it was, in [illegible] sulted upon the table or soon after the operation, or within the first 24 hours following upon the operation except where the operation had been performed for conditions which *might* of themselves prove fatal apart from shock—i.e., such cases as general peritonitis or acute appendix abscess, meningitis, empyema, &c., these cases were all excluded. The cases included as shock were such as intestinal anastomosis, reduction of dislocated hip, splenectomy, amputation of the hip, ruptured bladder, removal of a cerebral tumour, &c. No doubt several cases were included which did not die from shock; on the other hand many cases which die from shock do not die within the first 24 hours and in many cases where death follows quickly after an operation for general peritonitis or appendix abscess shock is the main cause of death, so that, on the whole, I am inclined to think that the figures give a very fair estimate of the percentage of death from shock and that, if anything, the result is too low rather than too high. Taking the minimum figure I found that there were 42 deaths out of the 200 which could be attributed to shock; or, in other words, 21 per cent. of the deaths following operations were either directly due to shock or shock was an important contributory factor in causing death. This shows, I think, that there is still a great field for the treatment or prevention of shock in lowering the mortality from the more severe operative procedures.

METHODS OF TREATING SHOCK.

Methods which simply treat symptoms.—Under this head I include treatment which has for its object keeping the patient warm by artificial means, the use of warm or stimulant enemata, the administration of alcohol or other stimulants, &c. Such treatment is based entirely upon the relief of symptoms and does not take into account the causes of the condition. The importance of keeping the patient warm is strongly insisted upon by most writers upon this subject and is one of the principal methods of treating shock advocated by many text-books. As I have already mentioned, in abdominal operations exposure of a large area of peritoneum for any length of time causes a considerable lowering of the body temperature and it is therefore important after such operations to attempt to compensate for this loss of heat by the application of external warmth.

The application of heat has, however, but little influence upon the blood pressure and certainly does not tend to raise it, except in so far as recovery of the vaso-motor centres will probably occur more readily if their blood-supply is at the normal rather than at a subnormal temperature. The application of external heat to the patient when it is carried to the extent of making him break into a profuse perspiration, as one not infrequently sees, is probably harmful, as it tends to lower the blood pressure by causing vaso-dilation of the peripheral blood-vessels.

The use of stimulants.—This has hitherto been one of the most popular methods of treating shock in almost all degrees of that condition. During the time that I was house surgeon I had considerable opportunities for watching the effects of treatment in cases of shock from different causes. The opportunities of seeing cases of shock which a house surgeon possesses are not easily obtained afterwards. Cases of shock either following operations or severe injuries or burns are constantly occurring in any large hospital but it is only the house surgeon who really is able to watch these cases constantly. During the period in which I acted in that capacity I was able to observe a large number of cases and one thing that struck me forcibly was the very disappointing results of stimulants, especially strychnine. In severe degrees of shock when the patient's circulation had almost failed hypodermic injections of strychnine, whether given in small or large doses, seemed in most cases to produce no effect. Thinking that the reason why strychnine had so little effect upon the circulation in bad cases of shock might be that owing to the deficient circulation it never reached the nerve centres I tried injecting it directly into the veins but in all cases the effect was the same—little or no improvement in the circulation resulted.

In lesser degrees of shock the effect of strychnine was more marked, the blood pressure being rapidly raised and marked improvement being apparent. I say apparent because as a rule the patient generally relapsed into a more severe degree of shock as soon as the effects of the drug had passed off. The most noticeable fact was that the more severe the degree of shock from which a patient was suffering the less was the effect of administering strychnine. Now it was at once obvious that this was just the reverse of what one would expect to find if strychnine really acted beneficially in the treatment of shock. In many of the cases where strychnine had entirely failed to improve the patient's condition I observed that a very marked improvement followed saline infusion into the veins. This showed that it was still possible to raise the blood pressure though strychnine was useless. At that time an article appeared by a distinguished surgeon in which the administration of strychnine hypodermically in large doses (from 20 to 30 minims of the liquor) was advocated in such cases. This was tried. The same effects, however, were observed—that is to say, in minor degrees of shock a marked result followed the injection, often resulting in great excitement or twitchings, but in the major degrees the result was the same as from the smaller doses—that is to say, there was none, except that in a few instances in which the patient subsequently recovered from the shock very pronounced symptoms of poisoning by the drug developed many hours after its administration. From the observation of a large number of cases I became quite convinced that strychnine was of very little value in the treatment of shock and that in many cases it directly contributed to a fatal issue. Alcohol also appeared to be equally valueless. At that time I was quite in the dark as to the reason for this and was going simply upon the results of clinical observations. Since the use of the sphygmomanometer to register blood pressure accurately in millimetres of mercury, however, the explanation of these clinical observations has become clear. Previously to the use of this instrument there was one fallacy which was very misleading in judging the effects of stimulants. The patient's condition was judged by feeling the character of the pulse and an increased flow through the artery gave the impression that the blood pressure had been raised. After the administration of alcohol especially, the pulse is often much more easily felt and one is led to suppose that the blood pressure has been raised. By observing the blood pressure with the sphygmomanometer after the administration of alcohol to a patient or to myself I have found that the blood pressure instead of being raised is actually lowered and that the apparent improvement in the pulse is due to vaso-dilation and an increased flow through the vessel.

Crile's recently published work upon the effects of stimulants administered to animals both in the normal condition and when reduced to different degrees of shock has entirely altered our views as to the use of stimulants. He found that in the normal animal the effect produced by the intravenous administration of alcohol upon the blood pressure was not great; the most constant result was a fall. There was no evidence that the heart beat more forcibly. In animals suffering from varying degrees of shock the effect of alcohol was to cause a still further fall in the blood pressure, the amount of the fall depending upon the size of the dose. Alcohol, in fact, increased the shock present and the more profound the degree of shock the greater was the decline in the blood pressure which followed its administration.

Strychnine.—In small doses strychnine produced very little effect upon the blood pressure in a normal animal. In large doses it produced a marked rise in the blood pressure and the blood pressure was maintained at a high level for a considerable time. A second dose was followed by a similar rise in the blood pressure usually not so high and not continued for so long. A third dose was followed by a slight rise and the effect passed off very quickly and on repeating the dose a point was soon reached when no effect at all was produced. After each dose the blood pressure fell to a lower level than before the injection and when the point was reached at which no effect followed the administration of strychnine the blood pressure had reached a very low level and the animal was in a condition indistinguishable from that of profound shock produced by traumatism.

Crile proved that the repeated administration of strychnine to a normal animal produced a condition of profound shock in every way comparable to that produced by traumatism, that this effect could be produced without causing convulsions, and that it was due to exhaustion of the vaso-motor centres from excessive stimulation. He proved that it was not due to any effect on the heart by first dividing both vagi and accelerants. Crile subsequently found that the quickest, easiest, and most certain method of producing shock in an animal for experimental purposes was by the administration of strychnine.

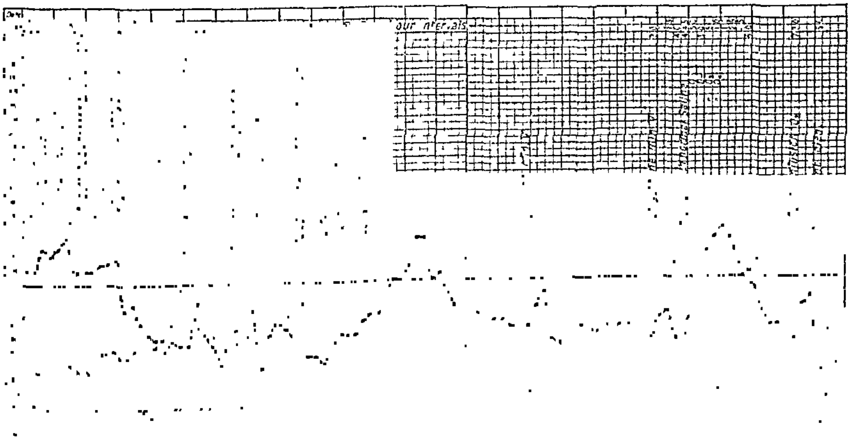
In animals suffering from shock the administration of strychnine caused a rise in the blood pressure which was proportional to the degree of shock. That is, if the degree of shock was slight there was a marked temporary rise in the blood pressure but if severe strychnine produced no effect. In all stages of shock the animal passed into a deeper degree of shock as soon as the effects of the strychnine had passed off. M. Roger has made a similar observation upon frogs. He found that if strychnine is injected into the veins of a frog no effect is produced if the animal is in a state of shock. With the sphygmomanometer the same facts may be observed clinically in patients suffering from shock. In the case of an elderly woman who had had an enormous fibroid uterus removed and who developed severe shock after the operation I was able to observe the results of the administration of strychnine. It was noticeable that just after the operation when the patient was in a dangerous condition brandy produced, if anything, a fall in the blood pressure. An injection of five minims of strychnine produced only a very slight rise and a repetition of the dose produced no effect at all. During the next four hours the patient recovered somewhat and the strychnine that had previously been administered produced a very considerable rise in the blood pressure and a third dose given a little later produced a rise to above the patient's normal level. Some hours later the pressure again fell and strychnine then produced only a slight rise. The patient gradually sank into a deeper condition of shock and an injection of strychnine of ten minims then only resulted in a very slight rise, the pressure very quickly falling to a level below that previous to the injection. The patient was then infused intravenously with saline solution and the blood pressure rose rapidly to a point considerably above the normal, only, however, to fall again in the course of the next two hours and the vaso-motor centres being completely exhausted, death ensued (see Fig. 10). I think there can be no doubt after an examination of this chart that the administration of strychnine in this case contributed to the fatal result by stimulating the exhausted vaso-motor centres and so preventing their recovery. This case is of considerable interest as it shows that even when the vaso-motor centres are so exhausted that a large dose of strychnine calls forth no vaso-constrictor response the blood pressure could still be raised by saline infusion to a point far above the normal level.

I know that these views with regard to the use of strychnine in the treatment of shock are opposed to accepted opinion and are contrary to the teaching of many able and experienced surgeons. It is not a question of opinion, however, *but of facts capable of proof.* It is only recently that it has been possible by careful observations upon the blood pressure to see the exact effects of stimulants in the treatment of sl[illegible] [illegible]nts of Crile and the clinical facts whicl[illegible] the way in [illegible] causation [illegible] conclusion—namely, that in all conditions and [illegible] true shock strychnine is not only useless but directly harmful, as it tends to increase and to hasten exhaustion of the vaso-motor centres. *The administration of strychnine in shock* is like beating a dying horse, it may call forth an effort if we beat hard enough but it hastens the end. And I am convinced that many a case of post-operative shock is rendered hopeless by the administration of this powerful drug which, but for the use of strychnine, might have recovered.

In the treatment of collapse such as would result from a severe hæmorrhage strychnine may be of value. When the blood pressure has fallen as the result of hæmorrhage to a level equal to that of profound shock the administration of strychnine in therapeutic doses causes a rise in pressure which is well sustained. In collapse the vaso-motor centres are not exhausted and consequently strychnine will raise the pressure by stimulating these centres to increased activity. We have thus an interesting contrast between the effects of strychnine in shock and in collapse. Saline intravenous infusion is, however, a better and more reasonable method of treating the collapse resulting from hæmorrhage as it directly combats the cause of the fall in blood pressure.

Digitalis.—In his experiments upon animals Crile found that digitalis caused a slight rise in the blood pressure when injected into an animal suffering from profound shock. The animals which were treated with digitalis, however, did not live any longer than the control animals and he came to the conclusion that digitalis was of little value.

FIG. 10.



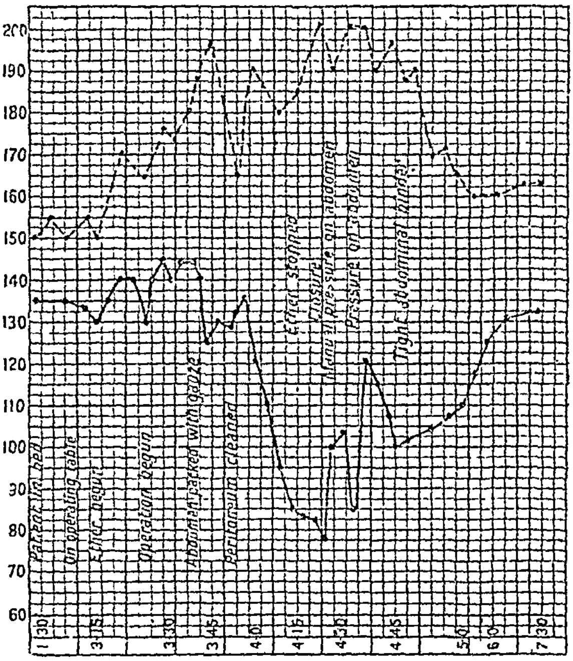
Th[illegible] blood pressure and the dotted line pulse rate. [illegible] enormous uterine [illegible] operation and [illegible] the normal level.

METHODS WHICH MECHANICALLY RAISE THE BLOOD PRESSURE.

Position.—It has been proved both by experiments upon animals and by observations upon man with the sphygmomanometer that position has a very marked effect upon the blood pressure. The best position is undoubtedly that usually advocated with the foot of the bed raised upon blocks and the head of the patient lower than his buttocks. This position tends to prevent the blood from accumulating in the abdomen and the lower limbs and assists the blood to flow from the great veins into the heart. This position raises the blood pressure in the essential part of the circulation—*that is, in the great* vessels and the brain—both in a normal individual and in a patient suffering from shock. Moreover, this is the position in a normal individual in which the highest blood pressure is found associated with the lowest pulse-rate; indicating that this is the position in which the blood pressure is most *easily maintained* at a high level. This was first demonstrated experimentally by Alexander in animals and upon man. It has since been confirmed by other observers, more especially by Stephens whose experiments upon 22 medical students I have already referred to. This position with the foot of the bed well raised (it should be raised at least a foot) is of the greatest value in combating shock and all patients suffering from shock should be nursed in this position until the blood pressure has once more returned to the normal level of health. I believe further that dangerous shock may often be warded off by placing patients after any severe operation in this position. At the North Eastern Hospital for Children it is the practice always to raise the foot of the cot of any child who has undergone any severe operation, whether shock is present or not, and I believe this to be very good routine practice. Once a patient suffering from shock or collapse has been placed in this position with the head down it is most important that his position should not be altered suddenly, as, for instance, by raising him for the administration of nourishment, &c., as the sudden alteration in blood pressure may result in a dangerous syncope; this has several times been observed. This is also one of the dangers of the Trendelenburg position. The act of lowering the patient into the horizontal position after an operation in which the Trendelenburg position has been used may result in a dangerous fall in blood pressure.

Compression of the abdomen.—Simple manual pressure upon the abdomen will raise the blood pressure in all conditions of shock and collapse. It acts by driving the blood out of the splanchnic area. In animals firm manual pressure upon the abdomen always causes an immediate and marked rise in the blood pressure. It is frequently possible by this means to double the blood pressure and however low the blood pressure may have fallen compression of the abdomen will always raise it. I have repeatedly observed most marked improvement in the pulse and arterial tension to follow this procedure in cases where shock has occurred during an operation. It is a valuable method of temporarily raising the blood pressure when the pressure suddenly falls during or just after an operation, whether it be from shock, sudden loss of blood, or from chloroform poisoning.

FIG. 11.



Blood-pressure chart of a case of laparotomy for general peritonitis. After Briggs and Cook.

Experiments upon animals showed that the blood pressure can always be raised during shock by compression of the abdomen and that in some cases the pressure does not again fall to its original level but remains higher than before the compression. The application of a tight abdominal binder acts in the same way and is at the same time a simple and effective method of raising the blood pressure during shock. I have seen great improvement in the patient's condition follow the application of a tight abdominal binder and if care is taken in its application to avoid compressing the chest and so embarrassing the respiration it is a most useful method of treatment, especially in abdominal cases (see Fig. 11).

Crile tried a number of experiments upon dogs to test the value of pressure in the treatment of shock. The animal was placed, after it had been reduced to a condition of shock, into a pneumatic tube and the pressure of the air in the tube was then raised. He found that in this way he had absolute control over the blood pressure in all conditions of shock. The blood pressure of an animal suffering from shock could in this way be raised to the normal level and kept there. Animals suffering from profound shock and treated in the pneumatic chamber lived longer than similar animals not so treated.

Arguing from these experiments and from the known physiology of shock, Crile attempted to treat human beings in the same way. For this purpose he had a pneumatic suit made in which the patient could be placed. This suit was so constructed that it enveloped the whole body except the head and chest and could be inflated by a foot pump. A uniform pressure was in this way exerted upon the whole body surface, constituting, in fact, an artificial peripheral resistance. He found that with this suit the blood pressure of a patient could be controlled within a range of from 25 to 75 millimetres of mercury. He was able with this suit to raise the blood pressure of a patient suffering from shock to a safe level and to keep it there while the operation was finished or afterwards until the vaso-motor centres had recovered. The suit was gradually deflated, the patient's pressure being meanwhile watched with a sphygmometer. It was found possible with this suit to maintain the blood pressure at a safe level for as long in one instance as 12 hours.

One case is worth quoting: it was that of a patient whose arm and shoulder had been mangled in a railway accident. On admission to the hospital the patient was in a condition of deep shock and on administering an anæsthetic for the purpose of amputating the arm the blood pressure fell and the radial pulse disappeared. The pneumatic suit was then put on and inflated. By this means the blood pressure, which had previously fallen to nothing, was rapidly raised to the normal pressure and maintained at that level during the operation for removal of the arm and the patient recovered. The results obtained by Crile with the use of this rubber suit afford a very striking proof of the physiological cause of shock.

This method of treating shock by raising the external air pressure and so substituting an artificial peripheral resistance for the lost peripheral resistance caused by the exhaustion of the vaso-motor centres promises to be of great clinical value and to be the most effectual method of treating that condition. Unfortunately it cannot yet be said to be a practical method. I should like to have been able to make some investigations with a pneumatic suit but the difficulties in the way are numerous and one item of no little importance is the cost of the necessary apparatus. The experiment was made by Crile at the Lakeside Hospital of building a pneumatic chamber in which patients suffering from shock could be placed and the atmospheric pressure raised. It had to be abandoned, however, owing to mechanical difficulties. Air chambers in which the air pressure can be raised to a considerable number of atmospheres and which are provided with air locks for entry and exit are now used for the treatment of workmen suffering from too rapid decompression on leaving the caissons where they work under high air pressure in the building of bridges and tube railways. These pressure chambers, or medical locks as they are called, are used, I believe, in most places where tunnelling under high atmospheric pressure is in progress. I do not think, therefore, that it would be impossible to construct a chamber or small ward in which the pressure could be raised to the necessary extent, provided with an air lock for entry and exit, and in which patients suffering from shock after severe operations or after burns or other injuries could be treated. Many lives might possibly be saved at a big hospital provided with such a ward. No doubt the money necessary for the construction of such a ward on the lines of the medical locks provided for workmen by the big engineering companies would be considerable and there would be numerous constructural difficulties. Some day, perhaps, such a ward may be built and an opportunity afforded for testing its value in the treatment of patients suffering from shock and other conditions of lowered blood pressure.

ON THE RELATION OF THE PARASITIC PROTOZOA TO EACH OTHER AND TO HUMAN DISEASE.[1]

BY E. J. McWEENEY, M.A., M.D. (R.U.I.), D.P.H.,

PROFESSOR OF PATHOLOGY, CATHOLIC UNIVERSITY MEDICAL SCHOOL, DUBLIN; BACTERIOLOGIST TO THE LOCAL GOVERNMENT BOARD FOR IRELAND.

IT is from the standpoint of an onlooker that I propose to-night to take a survey of the advances made during the past three years in our knowledge of the disease-producing protozoa. They reveal, in the first place, a surprising complexity of reproductive phenomena, and, in the second place, an equally surprising parallelism in the developmental cycle of forms which at first sight seem far removed. The protozoa, or one-cell animals, are divided into four classes: the rhizopods, the sporozoa, the flagellates, and the infusorians. The rhizopods are the lowest, comprising mainly amœbæ—shapeless masses of *protoplasm. The only one of these* which interests us to-night is amœba coli.

Many kinds of amœba occur in the human intestine. Just as the spores of many of the higher fungi, when placed in suitable nutritive conditions, pullulate in the form of yeast cells, and can only be distinguished from genuine yeast by a study of their development, so, of the many kinds of amœbæ occurring in the intestine, some are genuine—viz., the vegetative stage of rhizopods, whilst others are only amœboid stages in the development of higher forms, such as Trichomonas, Lamblia, and other infusorians. Genuine amœbæ *are divided into those provided with a shell, Thecamœbæ,* and those that are naked, *Gymnamœbæ.* At least one of the former and two of the latter sort are now known to occur in the intestine. With the representative of the shell amœbæ, Chlamydophrys stercorea (Cienkowski), and its complicated life-history we need not now concern ourselves, as its habit appears to be purely saprophytic. The two naked forms of amœbæ are genuine parasites. One of them is harmless and the other is one of the most dangerous of pathogenic protozoa. The former, which has hitherto been known as amœba coli (Lösch), has been re-named entamœba by Schaudinn. The second, hitherto called amœba dysenteriæ by such authors as admitted its existence, has been re-named [illegible] Schaudinn[2] found out [illegible] eba from the dangerous [illegible] frequently in the fæces of healthy persons, as was first discovered by Grassi. It is a shapeless mass of protoplasm, not showing a well-marked distinction into clear ectoplasm and granular endoplasm and possessed of a large and distinct nucleus. The obstacle to finding it in the healthy fæces is that its habitat being in the upper regions of the colon its vegetative stages die out as the intestinal contents become firmer on their way down. If, however, their downward course be hurried, then the amœbæ can readily be detected. The amœbæ have two distinct cycles of development: one vegetative or asexual, taking place in the naked state, the other displaying a primitive but unmistakeable form of sexuality and occurring inside a capsule or cyst. In the vegetative form the amœbæ either simply split in two or their nucleus divides into eight daughter nuclei, each of which takes a portion of the protoplasm so as to form a characteristic brood of eight young amœbæ which come apart. In the other, or sexual cycle, the amœba rounds itself off, comes to rest, contracts, and surro [illegible] which becomes the cyst [illegible] going reconstruction and [illegible] halves which copulate so [illegible] containing half of the two parent-nuclei. Each of [illegible] copulation-nuclei now divides twice and the divisions [illegible] eight young amœbæ which, however, cannot leave their [illegible] until it has been taken in by a new host and has had its wall softened in the stomach and the duodenum. The resemblance in general outline to the developmental process of the sporozoa will be at once manifest: asexual swarming in the primary host till it is exhausted or conditions bec [illegible] unfavourable; then sexuality with cyst formation [illegible] change of host.

[illegible] he pathogenic rhizopod entamœba [illegible] of the non-pathogenic entamœba [illegible] a clear, tough, outside layer or ectoplasm which enables it to penetrate between the epithelial cells, and, secondly, in not possessing a distinct, well-defined nucleus. Its tough ectoplasm enables it to force its way into the deeper layers of the mucous membrane where it multiplies and forms the undermined ulcers so characteristic of tropical dysentery and readily distinguished from the diphtheritic appearance presented by the bacillary form of the disease. The two sorts of amœbæ differ also in their reproduction. *The pathogenic form in its* vegetative stage divides into two or forms new individuals by budding. Brood form*ation does not occur. The* process of encystment is also quite different. It comes on when the patient is beginning to recover from his attack of dysentery and the fæces are becoming solid. The nucleus gives up most of its chromatin in granular form to the plasma and its *remains are expelled.* The plasma now projects from its surface a number of little knobs, each containing a particle of chromatin and measuring from three to seven micra in diameter. These break off after a while and each becomes surrounded by a capsule which ultimately becomes quite brown, hard, and opaque. These "spores" are then expelled with the fæces and serve to infect a fresh host.

In my presidential address delivered in 1901 before *the* Royal Academy of Medicine in Ireland I spoke of the rôle of amœbæ in the following terms: "The general *conclusion* to which I incline after a careful survey of the literature is that the amœba coli is in all probability either wholly or partially responsible for the causation of one form of dysentery—that termed '*tropical*' *and* which is not endemic in this country." Subsequent *investigation has borne out this view. One of Schaudinn's experiments seems quite conclusive. He allowed a small* fragment of fæces from a case of dysentery contracted in China to dry in the air, suspended it in water, made a number of sl [illegible] tions, and by searching them [illegible] on the mechanical stage he [illegible] contained nothing resembling the cysts of entamœba coli but only the small brown spores of entamœba histolytica. There were no amœbæ, these having been destroyed by drying. The cover-glasses were then removed and the fæces washed off with clean water, made up to about one cubic centimetre, and administered with meat and milk to a young healthy cat, the fæces of which had been proved by careful examination to be free from amœbæ and their cysts. Three days afterwards the cat began to pass slimy fæces streaked with blood. These were found to be swarming with the typical entamœba hystolytica. Next day the animal died from dysentery. The necropsy showed characteristic ulceration of the large intestine with crowds of amœbæ in all stages of penetration into the intestinal wall. There were no cysts, the animal having died in the acute stage of the disease. In order to see whether the amœboid stage *could propagate the disease Schaudinn* administered large quantities of this fæcal matter to another cat. It remained quite healthy. Its fæces were examined for four weeks and no amœbæ were detected. It was then given a small portion of the same dried-up spore-containing fæces from the Chinese case that had been used in the other experiment. Within six days, amœbæ appeared in the fæces. This cat developed dysentery and died from it in about a fortnight. From this it would seem that the disease is not propagated by amœbæ introduced per os. The older experimenters, from Kruse and Pasquale onwards, had often succeeded in producing infection by the [illegible] of amœbæ per rectum. This rectal trans- [illegible], however, hardly be realised under natural [illegible] and, accordingly, it is to the dried-up spore- [illegible] present in dust and water that we must [illegible] dysentery. Whether the amœbæ [illegible] the acute stage will, if gradually dried, become converted into spores outside the body, or whether the amœbæ that are going on to spore formation receive their impetus along that track whilst still in the bowel, does not seem to be quite clear. In any case the [illegible] of these observations is obvious. The [illegible] entery must be pre- [illegible] water or from being [illegible]

The next class is that of the sporozoa, so called because at one stage of their life-history the individual breaks up into a number of minute reproductive bodies resembling the spores of fungi or mosses and, like them, often contained within a cyst or thick-walled capsule. Amongst the chief orders of this class are the gregarines, which mostly live in the intestines of crustaceans and insects; the coccidia, many of which inhabit the digestive tract and its annexes in mammals, birds, and various invertebrates (myriapods, &c.); and the hæmosporidia, or parasites of the blood corpuscles, which are the cause of malaria and to which, therefore, a very special interest attaches. All these organisms, however different their vegetative stages, have in common a certain ground-plan of life-history, though varying in individual cases and with regard to matters of detail. This life-history comprises two main features, alternation of generations and change of host. Alternation of generations means that a sexual method of reproduction alternates with an asexual method, whilst the term "change of host" does not, of necessity, imply a change of host-*species*, but in many cases only a change of host-*individual*. The general idea underlying the parasitism of these organisms is that once the sexually produced reproductive body, or spore, finds its way into a suitable host and into a suitable cell of that host—for they are intracellular parasites—it rapidly attains its full size and splits up without the intervention of sexuality into a number of fragments which fall asunder and, invading fresh cells of the same host, repeat the process. The host-animal thus becomes speedily pervaded by swarms of parasites and the resultant disturbance of function is the disease. After a time, owing to the production of specific antibodies or to the exhaustion of the reproductive power of the parasite under the strain of repeated asexual division, this process gradually ceases and specially differentiated male and female forms appear and copulate. The fertilised female forms a cyst containing spores, which have to be transmitted to a fresh host before they can develop. The points at which the greatest variability obtains are, first, the place and time of conjugation, and secondly, the arrangements for transfer from one host to another. Where the organism passes its asexual stage in the blood, transfer must necessarily be effected by the only agency whereby blood is at all frequently removed from the vessels—i.e., blood-sucking invertebrates, such as flies and ticks. The intermediate host of blood-inhabiting parasites is, therefore, an invertebrate blood-sucker. Some of the blood parasites—those of malaria, for example—avail themselves of the invertebrate host as the scene of their sexual reproduction and multiply enormously within it. Others, such as the trypanosomes of the mammalia, remain, so far as we are at present aware, quite passive within their cold-blooded host and use it merely as a vehicle. Others, again (some of the piroplasmata), in some mysterious way pass on into the eggs of the invertebrate host and infect its young brood. On the other hand, when the parasite passes its asexual stage in a cavity of the host that is connected with the outer world (the coccidia), the problem how to escape is comparatively simple, and an intermediate host may be dispensed with.

---

[1] Abstract of a paper read before the Epidemiological Society on Feb. 17th, 1905.

[2] Arbeiten aus dem Kaiserlichen Gesundheitsamte, Band xix., 1903

In order to characterise readily these several stages and to emphasise homologies, it is necessary to adopt a systematic nomenclature, and I accordingly use that elaborated by Schaudinn and Lühe, according to which

The [illegible] the mature asexual individual.
[illegible] to the pieces into which the Schizont [illegible]

" Gametocytes is applied to the forms which produce or become converted into the sexual individuals:—

viz., Macrogametocyte ...	The *asexually produced* individual which, by chromosomic reduction, becomes converted into a female;
and Microgametocyte ...	The *asexually produced* individual which, by chromosomic reduction and nuclear division, becomes converted into a *number* of males.
Gametes	The sexual individuals:
viz., Macrogametes ...	Females (the ova of the metazoa).
And Microgametes ...	Males (the spermatozoa of the metazoa, antherozoids of the higher cryptogams).
Zygote	The fertilised macrogamete.
Ookinet	The zygote when capable of locomotion.
Öocyst	The zygote when it has come to rest and is surrounded by a thick capsule.
Sporoblasts	Secondary cysts or spore bags formed within the oocyst.
Sporozöites	The final products of the act of sexual reproduction—minute bodies formed often in large numbers within the öocyst and which, on being removed to the new host, give rise to the schizonts.

The life-history of the parasites of human malaria, as established by the labours of Laveran, who discovered them; Golgi, who differentiated them into species; Ross and Manson, who discovered the change of host; MacCallum, who recognised their sexuality; and Grassi, who identified the mosquito, has been more fully worked out during the last three years and numerous important details have been added. Plasmodium vivax, the cause of tertian ague, has been minutely studied by Schaudinn[3] at an ague-stricken village near Rovigno on the Adriatic. Some of his observations regarding the sexual process are of special interest. It starts in from ten minutes to half an hour after the blood has been sucked in by the gnat. The microgametocyte, which is readily recognised by its hyaline plasma, large oval nucleus, and coarsely granular pigment, suddenly shoots forth from four to eight curved filaments, from 20 to 25 micra long and one micron at thickest. Meanwhile the macrogamete has been preparing itself for fertilisation by ejecting part of its nucleus. This process appears to be homologous with the extrusion of the polar bodies by the metazoan ovum. The number of chromosomes is thus reduced by one-half. The extruded matter may possibly, by its disintegration, provide a diffusible substance acting chemiotactically on the microgametes and causing them to approach the female, in the same way as the canal cells of the archegonium of ferns yield malic acid which attracts the antherozoid. The female then protrudes a "receptive eminence," and as soon as one of the males has adhered to this it is at once withdrawn carrying the struggling microgamete in with it. Only the one male obtains admission in the case of the malarial parasites but in the coccidian cyclospora caryolytica, which causes an infective form of enteritis in the mole (talpa), what is called polyspermy occurs.[4] Quite a number of male gametes force an entrance into the macrogamete. Only one of them undergoes the fertilising fusion, whilst the others break down and serve as food for the developing zygote. The presence of superfluous males, however, is apt to disturb the proper relation of male and female pronucleus, and give rise to interesting pathological changes described by Schaudinn. In the tertian parasite only one favoured microgamete gains access, and no sooner has it done so than a coat of mucus is secreted by the female which keeps away the excluded males and is homologous with the cyst wall of the coccidia. The zygote now becomes a motile öokinet, and this becomes an öocyst. Some of the liberated sporozöites, according to Schaudinn, obtain access to the ovary of the gnat and infect the developing ova, so that the young brood next spring harbours the parasite, and the young mosquitoes can confer the disease without having previously sucked blood—a fact of great epidemiological importance if it be confirmed by subsequent observation. Finally, Schaudinn observed the entrance of the sporozoite into his own red corpuscles, thus completing the developmental cycle.

I now come to the last part of my subject—namely, the order of flagellates, to which belong the trypanosomes. Three years ago, in the address already referred to, I gave some account of these parasites in connexion with the diseases of animals known as nagana, due to trypanosoma Brucei, and surra, due to trypanosoma Evansi, and I described the rôle of the tsetse fly as carrier of the former. During the three years that have since elapsed the rôle of these parasites as disease producers amongst the lower animals has been greatly enlarged. Dutton and Todd[5] found a disease of horses in Gambia to be due to trypanosoma dimorphon. Elmassian,[6] followed by Voges and Lignières, has shown that the disease of horses in South America known as mal de caderas is due to another trypanosome (trypanosoma equinum). The sexual malady of stallions and brood-mares known to the French as dourine, or mal de coit, is due to trypanosoma equiperdum, which was first discovered by Rouget in 1896.[7] The so-called galziekte or gall-sickness of bovines in the Transvaal has been shown by Theiler to be caused by a species called after him trypanosoma Theileri.[8] Other forms have been described in the smaller mammals, as well as in birds, reptiles, amphibians, and fishes. But the great access of interest in the study of trypanosomes is due to the fact that they are now known to produce disease in the human race. In December, 1901, Dutton[9] was the first to recognise as a trypanosome *the vermicule* previously seen by Forde in the blood of a European patient in the hospital at Bathurst. He described it accurately and named it trypanosoma Gambiense. In April, 1903, Castellani[10] discovered a trypanosome in the cerebro-spinal fluid of natives of Uganda affected with sleeping sickness and this malady has consequently come to be *regarded as one* of the manifestations of human trypanosomiasis. David Bruce[11] with his fellow workers, Nabarro and Greig, brought home the propagation of the disease in Gambia to the fly glossina palpalis. Finally, there is the discovery, so far back as 1900, by Leishman and, independently in 1903, by Donovan, in smears of spleen pulp from cases of *splenic* cachexia in India, of parasites which Rogers[12] has shown to be stages in the development of a trypanosome.

A correct idea of the structure of a trypanosome is essential to an understanding of what follows. Its fish-like body, twice or thrice as long as a red corpuscle, is fringed along one side with the undulating membrane, which is prolonged at one end into the flagellum. In the body is a large nucleus, and towards the posterior end a smaller dot-like mass of chromatin from which originates the margin of the undulating membrane—the edge which is prolonged into the flagellum. The nature and homologies of this smaller mass of nuclear substance have given rise to lively discussion. There seems to be no doubt that it gives origin to, and presides over, [illegible] undulating me[illegible] the colour reac[illegible] method) are part and parcel of this mass, which I shall therefore term the blepharoplast. Trypanosomes bear a close resemblance to the spermatozoa of some animals (bombinator). They multiply mostly by unequal longitudinal division, more rarely by multiple division (rosette formation). The first part to divide is always the blepharoplast. They are agglutinable by foreign or immune serum, as was shown by Laveran and Mesnil. One species at least,[13] that of the rat, has been successfully cultivated on blood agar. Until the researches of Schaudinn trypanosomes were looked upon as independent organisms and were not known to possess any trace of a sexual mode of reproduction.

In the blood of the stone owl (athene noctua) Schaudinn[14] found three distinct protozoal parasites. First *there* was the proteosoma, the development of which in the mosquito, culex nemorosus, had been so brilliantly discovered by Ross and subsequently studied by Koch. Then there was another plasm[illegible] previo[illegible] there[illegible] as 1894 by Danilewsky. The two last-named parasites own culex pipiens as their intermediate host. Previous observers had followed the development of the halteridium (called by Schaudinn trypanosoma noctuæ) as far as it goes on in the hanging-drop of blood. Further they could not pursue it, not knowing the species of mosquito which serves as its intermediate host. Schaudinn finds that as the result of fertilisation an öokinet is formed which moves along like a slug by the aid of its own mucus towards the front of the mosquito's stomach *and there becomes converted into a trypanosome.* The nucleus divides unequally so as to form a hetero-polar spindle. The larger (left) half enters the resting stage, whilst the *smaller (right)* half, which is now in the ectoplasm at the periphery, again divides, forming another hetero-polar spindle with the long axis parallel with that of the öokinet and the smaller pole forwards. The chromatin of this spindle forms the skeleton of the locomotive apparatus of the future trypanosome, the thickest *thread forming* the free edge of the membrane, whilst the posterior centrosome becomes the blepharoplast. Thus a trypanosome is formed and of these Schaudinn describes three types: the "indifferent," the "female," and the "male." The öokinet, which is to develop into a "female" trypanosome, has darker protoplasm and a smaller nucleus than the form which he calls "indifferent." It goes through the same nuclear processes, the result being the formation of a larger trypanosome, which is provided with a relatively small flagellum and is *therefore less active in its movements.* The "female" trypanosome ultimately comes to resemble a mature gregarine and possesses a marked power of resisting external unfavourable influences. If, for instance, the mosquito is starved and then kept on ice all the parasitic forms within it die out save the "female" trypanosomes, *which lie buried between the epithelial and elastico*-muscular coat of the intestine, last through the winter, and infect the brood of eggs laid next spring. Multiplication of this gregarinoid stage takes place by a process termed by Schaudinn "parthenogenesis" and which he homologises with the re-infection of the warm-blooded host *in malaria, the so-called "relapses." The forms* which persist in the blood of old-standing cases of malaria are, according to him, old females (macrogametes) [? macrogametocytes]. After a time these "sink" to the level of schizonts; in other words, produce a brood without having been fertilised. This mode of reproduction—the skipping of the sexual generation—appears to me to be homologous with the phenomenon amongst ferns, first described by De Bary under the name of "apogamy." The öokinet which is to form the "male" trypanosomes is distinguished *ab initio* by its small size, large nucleus, and absence of reserve material in its protoplasm. By a process of reduction it gets rid of one-half of its nucleus—the half which is preserved in the female—and the remainder splits up so as to form eight minute trypanosomes. These Schaudinn regards as microgametes which, however, are unable to perform their physiological function of fertilisation. This act is only performed at one period of the life-history of the parasite viz., within a few minutes of its arrival within the stomach of the mosquito.

The intestinal canal of the mosquito thus becomes inundated with "trypanosomes" of all three kinds. Sometimes they are produced in such swarms that their resting stages occupy all the epithelium and the mosquito dies from the disease. Ordinarily the insect feeds three times and it is during these three periods of digestion that the parasites make their way down the bowel, through the wall of the colon, and so into the blood stream, whereby some get carried to the ovaries, where they infect the young brood; most, however, are carried to the front of the body cavity, into the head, where they accumulate round the pharynx and *ultimately rupture into it and so obtain access to the lumen* of the proboscis. The mechanism of transference to the warm-blooded host is extremely interesting and as the parasites of human malaria may possibly be transferred in the same way it seems worth while to mention the details. Culex pipiens possesses œsophageal diverticula which become *distended* with gas and may be termed "gas bags." The gas is carbon dioxide, which is evolved by a sort of yeast-like fungus always present in the insect's stomach from traces of glucose present in blood, or—much more abundantly—from glucose present in the plant juices which the insect occasionally sucks At the commencement *of the* act of suction, when the insect has its proboscis buried in the skin of its victim, its body undergoes one or more violent contractions which eject the contents of its fore-gut and "gas bags" into the skin. These contents comprise gas, saliva, and whatever particulate matter is present—viz., yeast cells and sporozöites. Schaudinn looks upon this contraction as a sort of dyspnœal effort due to the entrance into its tracheæ of the *CO_2-laden air* which bathes the skin. He succeeded in producing the contraction artificially by placing an infected culex on a cupped slide, with its proboscis in a drop of glycerine under a cover-glass, and its body projecting over the hollow. In this he evolved some CO_2 from a fragment of chalk and a droplet of *acid*, and he observed that the gnat's body underwent a violent contraction, which had the effect of expelling *into* the glycerine its contained gas, yeast cells, and sporozöites. Viewed teleologically, the effect of the injected CO_2 would be to paralyse the thrombocytes and in other ways to delay the coagulation of the blood. The hyperæmia and pain caused by the bite he considers to be due to the enzyme of the yeast cells. He dissected out the "gas bags" and pushed them into a fine puncture in his own skin, with the result that the typical swelling, redness, and itching came on at once. The salivary glands he found quite inoperative. The effect of the "gas bags" appears to depend on the quantity of yeast cells contained in them, for it was much more marked when the yeast had been allowed to proliferate actively as the result of feeding the gnat on plant juice. The fungus is not a true yeast, but a yeast-like stage in the life-history of one of the entomophthoreæ, fungi with which we are all acquainted in the shape of the well-known empusa muscæ, which kills flies in the fall of the year and causes their bodies to adhere to the window pane surrounded by a white cloud of ejected conidia.

Let us now follow the trypanosomes into the blood of the owl, whither they are carried by the bite of the culex. Such "males" as are conveyed in the fully differentiated state die off. The mature "females" are usually too large to pass the gnat's proboscis. It is the "indifferent" forms and young "females" that thrive in their new surroundings. Adhering by their flagellum to the red corpuscles they bore their way in, withdra[illegible] ow larger in the plasmodial form [illegible] Koch, and other observers. They do *not* proceed to form asexual rosettes (schizonts)—a fact expressly drawn attention to by Koch who could not find in the blood of his artificially infected sparrows and pigeons any trace of this form of multiplication so abundantly met with in human malaria. The intracorpuscular parasites leave their host cells only during the night and in the deepest recesses of the circulation—the spleen and bone marrow. There they swim about for a while as free trypanosomes of all three varieties above described. During the day they mostly go back to the corpuscles. Thus, they change about at intervals for six days, by the end of which time they have attained their full size. Finally emerging, the full-grown parasite now multiplies by repeated acts of longitudinal fission till the products have attained their minimal size. The excessively minute flagellates so formed penetrate into fresh red corpuscles till the blood becomes fairly inundated. Then they die down and only a small number of "indifferent" forms survive, which become gradually evolved into macro- and micro-gametocytes and can only complete their evolution in the body of the gnat.

I have dwelt thus at length upon the history of this parasite on account of the light it throws upon the nature of the Leishman-Donovan body. These parasitic bodies are contained in large endothelial cells of the spleen and marrow; so, for a time, are the halteridium parasites. The Leishman-Donovan bodies possess two nuclei—a large oval and a small rod-shaped one; so do the involuted intracorpuscular trypanosomes of halteridium. Finally, we have the brilliant discovery by Rogers that blood containing Leishman-Donovan bodies gives rise to trypanosomes. The details given by Rogers tend to support the supposition that the life-history of the parasite of human cachexial fever runs on the same lines as that of owl malaria. For example, "the splitting up of the parasite into two, the separation usually beginning at one end," suggests the longitudinal division of the trypanosomes; and "the presence of smaller pear-shaped flagellated bodies like those described by Plimmer in tsetse fly disease," which are evidently involution, or immature forms, also described by Laveran and Mesnil in their recently published text-book,[15] under the name of *mises en boule*. Finally, there is the fact that the trypanosomes were only developed in Captain Rogers's cultures at a low temperature (22°), which would point to their being naturally produced outside the warm-blooded host, in a blood-sucking invertebrate, such as a bug or a mosquito. There can be little doubt that the original opinion of Major Leishman with regard to these bodies is correct and that kala-azar and cachexial fever will prove to be a form of human trypanosomiasis. The same opinion doubtless holds good of the bodies found in the granulation tissue of Delhi boil and tropical ulcer.

Remarkable as is the connexion so established between the malarial parasite and the trypanosome, it is, at any rate, a connexion between one protozöon and another. But the developmental cycle which I am now about to recount will, if established by further investigation, effect a still more surprising connexion—viz., between a malarial parasite and an organism hitherto looked upon as a bacterium, spirochæte. Sporozoites ... [illegible] question was discovered so far back as 1891 by Danilewsky of Charkow[16] in the blood of athene noctua and called by him the leucocytozöon, from its dwelling in the white corpuscles. Both its warm-blooded and cold-blooded hosts (culex pipiens), as well as its general aspect, are identical with those of halteridium. In the mosquito's stomach its stationary macrogametes are fertilised by the motile microgametes. An öokinet is thus formed which becomes spirally coiled, the coils afterwards coalescing. This process is remarkably like what occurs in the development of the sexual fructification of the cleistocarpous ascomycetes, such as eurotium. The original nucleus divides into a vast number, each of which presides over a territory of protoplasm which gradually becomes differentiated into a trypanosome-like body, with blepharoplast, undulating membrane, and flagellum. Of these, as in halteridium, there are three sorts—"indifferent," "female," and "male"—all very minute. As the result of repeated division the individuals may become so small as to become not only incapable of measurement but of being perceived individually even with the highest powers. It is only when agglutinated in rosette form that they can be well seen and Schaudinn has no doubt that they would constitute a *filtrable* virus: that is, one capable of passing the pores of a porcelain filter and therefore in the same category as those of pleuro-pneumonia, foot-and-mouth disease, and perhaps of small-pox. These minute trypanosomes increase greatly in length and become spirally twisted round their long axis so as to constitute what have hitherto been termed spirochætes. Now the leading pathogenic spirochæte hitherto known is S. Obermeieri, the cause of relapsing fever. It has been observed to move equally well in either direction, "forwards" or "backwards." But trypanosomes always move flagellum first, and this would seem to be a serious difference between them and spirochæte. Schaudinn states, however, that these long, thin trypanosomes divide longitudinally and that the two new individuals *remain coherent by their non-flagellated ends*, and can accordingly move in *either* direction. They continue to cohere until each individual has again divided in the same way. These spirochæte-trypanosomes agree with the trypanosomes of the mammalia and differ from those of birds (halteridia) in becoming agglutinated by their *non-flagellated* ends. It is at the end of the first digestive period of the mosquito that these spirochæte-like trypanosomes are developed from the öokinet, inundate the body cavity and infect the ova. On reintroduction, natural or experimental, into the owl, they begin by multiplying enormously in the spirochæte form before proceeding to the formation of sexual individuals. To me it seems surprising that neither Danilewsky nor the other workers who observed the intra-corpuscular stage of this parasite should have seen the spirochæte. The cell preferred by this parasite is not the mature red corpuscle, nor yet the mature leucocyte, but the hæmoglobin-free precursor of the former—the erythroblast. This accounts for its presence mainly in the spleen and marrow (cf. the behaviour of the Leishman-Donovan body). In human relapsing fever Metchnikoff observed that when the spirochæte disappears from the blood at the crisis it accumulates in the spleen. The parasites undergo successive stages of intra- and extra-corpuscular existence in the blood of the owl and on removal from it by culex pipiens at once proceed to the formation of large rounded macrogametes with dense protoplasm and small active microgametes which look like a minute trypanosome or a spirochæte. Fertilisation gives rise to the öokinet from which we started. Should this developmental cycle be confirmed by other observers then it follows that trypanosoma and spirochæte are really only different names for the same thing. This would account for the non-cultivability of the spirochæte on ordinary substrata and the persistence of the parasite in the spleen after its disappearance from the general circulation. It would also appear probable that its propagation would be effected by some blood-sucking parasite as has actually been found to be the case with the "spirillosis of fowls," recently described by Marchoux and Salimbeni,[17] who found that spirilla were conveyed by the bird tick, argas miniatus. I am not aware that the intermediate host of the spirillosis of ducks described by Sakharoff, or of that of oxen quite recently described by Laveran,[18] has been ascertained. In the case of human

[18] Comptes Rendus de la Société de Biologie, April 20th, 1903, No. 10.

relapsing fever it seems most probable that bed-bugs carry the infection. Karlinski[19] found abundant spirilla in the bugs captured in Bosnian houses where the inmates suffered from the fever, whilst he could find none in bugs obtained from houses where there was no fever. He found that the spirilla persisted for 20 days in the bugs. The human "tick" fever in the Congo has recently been found by Dutton and Todd to be caused by spirilla which are conveyed [illegible] oo long, would be swollen to [illegible] to attempt to refer in detail to the piroplasma parasites. I am, however, absolved from the task by the fact that this society has already been this season the recipient of a very admirable communication from Professor G. H. F. Nuttall, F.R.S., on the subject of Ticks and Tick-transmitted Diseases, which practically covers the ground. I will merely mention that Kossel and Weber[20] of the German Imperial Health Office have found [illegible] blood of cows affected with [illegible] the intestines of ticks that [illegible] ows. Furthermore, Theiler, and quite recently Bowhill,[21] have found both trypanosome and spirochæte forms in the blood of oxen and dogs affected with piroplasmosis. Judging by analogy it seems not improbable that the hitherto unseen parasite of yellow fever may prove to be a spirochæte too small to be seen with the highest powers of the microscope.

Dublin.

THE TREATMENT OF PLEURITIC EFFUSION BY PARACENTESIS AND INCISION IN SEROUS EFFUSION, EMPYEMA, AND PYOPNEUMOTHORAX.[1]

By SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN AND LECTURER ON MEDICINE AT ST. BARTHOLOMEW'S HOSPITAL.

THE invitation to read a paper before this time-honoured society was a compliment which I greatly appreciated but it brought with it the difficulty of deciding upon a subject which should be of sufficient general interest and at the same time one upon which I could say anything worthy your attention. My difficulties were, however, solved by the choice being made for me and I was told that the treatment of pleuritic effusion would be acceptable. This selection certainly commended itself to me as dealing with a common affection of which we all should have experience and probably views of our own, while it was at the same time a subject which had always been of special interest to me and upon which I might speak freely. The general treatment of pleuritic effusion would lead me into fields too wide to cover within the time and I shall restrict myself to the treatment of serous effusion, empyema, and pneumothorax by paracentesis and incision.

I.—SEROUS EFFUSION.

I do not propose to enter upon the question of diagnosis. In most cases this is easy and where difficulty arises the needle will settle it. If the needle be clean and ordinary care is exercised the exploration is simple and safe. Serous fluids do not change their character except as the result of fresh infection with some pyogenic organism. If a serous effusion become purulent after the passage of a needle the presumption is that the operation was not aseptic. It is most important, therefore, even for such a small operation as an exploratory puncture, that the strictest antiseptic precautions should be taken—the side washed, scrubbed, and most scrupulously cleansed, as well as the needle sterilised. With these precautions the needle may be passed as many times as necessary with impunity. I have tapped a case 36 times and left the fluid at the last tapping as clear and uninfected as at the first. Dieulafoy taught this long before the advent of antiseptic surgery, though his teaching was not generally accepted.

To understand the principles of treatment of pleuritic effusion it is essential to have correct views of the way in which the fluid is got rid of from the pleura when it is left alone and disappears spontaneously. It is often said to be absorbed, yet the part which absorption plays in the removal of the fluid is very small. The pleura is a lymph sac connected through the stomata or small pores with the lymphatics of the lungs on one side and of the thoracic walls on the other. The lymph trunks on both sides have valves directed away from the pleura. Such an arrangement of valves indicates a circulation and there is such a circulation of lymph in health through the pleural sac, lymph passing into the sac from the blood-vessels and being removed by the lymphatics, and these processes are so adjusted that no fluid accumulates in the pleural sac. The sac is accordingly [illegible] always contains a [illegible] to keep the surfa[illegible] enters.

This action may be called the "lymphatic pump." The movements of respiration work the pump. Inspiration sucks lymph in; expiration, by the help of the valves, drives it out; the direction of the lymphatic circulation being in the lungs from the pleura to the root of the lung and in the thoracic walls from the pleura to the adjacent lymphatic glands. Fluid might therefore accumulate in the pleura in two ways. On the one hand, more fluid might enter than could be removed (this is what probably occurs in hydrops pleuræ or dropsy); on the other hand, owing to some interference with the pump mechanism, less might be removed than is necessary. In inflammation of the pleura both causes are in action, the inflammation causing increased exudation, while the inflammatory swelling and fibrinous [illegible] exercised by the fluid upon the stomata and superficial lymphatics creates a further obstruction. Lastly, a large effusion makes difficulties for itself by greatly reducing or abolishing the respiratory movements—that is to say, the force by which the lymphatic pump is worked. As the effusion grows in size the respiratory movements on the affected side become less and less and ultimately cease, so that the pump stops working. When this point has been reached, even if the effusion increase no more, what is already in [illegible] for the pump does not work. [illegible] which it [illegible] now will start the pump again. Thus we have an explanation of what is otherwise not easy to understand—viz., the removal of only a few ounces of a large effusion being followed by the gradual disappearance of the rest. This fact is not to be used as an argument for the deliberate removal on tapping of only a portion of the effusion. On the contrary, the pump should be given every chance to work and all the fluid should be removed which can be conveniently obtained. This much of theory is necessary [illegible] must be based upon correct [illegible] and pleuritic effusion other than by tapping I do not propose to enter save to refer in passing to a once popular line of treatment—the so-called derivative method. It is based upon the nec[illegible] absorption by [illegible] fluid be prom[illegible] the skin, the [illegible] povershed wil[illegible] itself ready to [illegible] be "absorbed. [illegible] found wanting, [illegible] theory.

I now turn to the ques[illegible] The indications for paracentesis are gi[illegible] its duration, and especiall[illegible] I have already shown how [illegible] to removal. It therefore follows that where the pleura is full of fluid and the respiratory movements are completely abolished the sooner paracentesis is performed the better. [illegible] has existed some [illegible] Yet it is not [illegible] there may be [illegible] sufficient thickening [illegible] to give dulness on percussion though the lung may have so far expanded and the fluid disappeared that surprisingly little fluid, if any, is obtained on paracentesis. In such cases the respiratory murmur and vocal resonance are better guides to the intrathoracic condition than percussion.

[20] Arbeiten aus dem Kaiserlichen Gesundheitsamte, Band xx., 1903, p. 436.

[21] Journal of Hygiene, 1905, No. 1.

[1] A paper read before the Medical Society of Plymouth on Feb. 12th.

Early tapping—i.e., tapping in the first few days of an effusion—has been advocated chiefly for two theoretical reasons: (1) that early tapping shortens the duration of the attack, and (2) that if the lung be left long compressed by fluid it will become bound down by adhesions and thus prevented from re-expanding. Neither of these reasons is strictly accurate. The duration of the pleurisy is not shortened by tapping. The inflammation continues its course completely unaffected by paracentesis. It is not with serous effusion as it is with an empyema, where the removal of the pus is followed by the fall of the temperature. On the contrary, the temperature remains as high as before and continues raised until the inflammation comes to a standstill irrespective of whether paracentesis be performed or not. Again, though the lung may, if long compressed, be bound down by adhesions, still it may be compressed by fluid for weeks or months and yet remain perfectly free and expand readily when the fluid is removed. I have seen this occur in two cases in which the side had been full of fluid for 18 months before paracentesis was performed.

The occurrence of *dyspnœa* presents some points of special interest. Of course, as the effusion increases the respiratory capacity of the lungs is diminished and there must therefore always be some shortness of breath, but, other things being equal, the amount of dyspnœa varies with the rate of effusion—i.e., with the rapidity with which the fluid has accumulated; thus it may be trifling with a very large effusion if the fluid has accumulated slowly and severe with a much smaller effusion if it has formed rapidly. The respiration can adapt itself to the altered conditions if time be given, but if not it becomes embarrassed and dyspnœa results. But dyspnœa may arise and rapidly become urgent with effusion in a way which requires a different explanation and has a much more serious significance. A patient may have the side full of fluid and the organs greatly displaced, so that the total respiratory capacity is reduced to one-third or one-quarter of what it would normally be and yet for days or weeks no particular dyspnœa be present. All at once, without any warning, dyspnœa arises and rapidly becomes urgent, so that if relief be not quickly given the patient will die from suffocation. This is due to what is called "congestion" of the opposite lung. But that lung has been pathologically in a condition of congestion throughout, inasmuch as it has had to do the work of the two and consequently to deal with double the normal quantity of blood. It has been able for a time to meet these demands made upon it successfully and has given no clinical signs of congestion. All at once those signs appear—viz., wheezing and crepitation and the expectoration of fluid which may be blood-stained. The extravasation of fluid into the tubes upon which these signs depend is not due to bronchitis, for it is not an inflammatory exudation. It is the result of functional breakdown or incompetence in which probably both the heart and the lungs take their share. The signs of congestion arising in the one lung when the other is out of gear are of very grave significance. In the case of effusion they give the indication for immediate paracentesis but where they depend upon a condition to which no relief can be given, as in pneumonia, they are of the gravest omen and signify a fatal termination.

I saw an instance recently in a young lad who had effusion following pneumonia. He was breathing 70 in the minute and was bathed in a cold clammy sweat; the rattling and wheezing in the other lung were extreme. The lad was conscious but was suffering horrible distress and begged piteously for relief. So ill was he that I did not venture to examine the chest much; indeed, I dreaded lest the mere prick of the needle should prove fatal. The removal of two pints of fluid gave immediate relief and snatched him out of the jaws of death. He is living still and I hope that he will get well. I thought the case absolutely desperate at the time of operation but one learns never to despair.

Indications against paracentesis there are none. The temperature is entirely unaffected by tapping for good or ill. The risk of the conversion of the effusion from serum to pus is, with proper precautions, *nil.* Lastly, the statement still often made that the compression of a tuberculous lung by fluid is so far of advantage that it checks the further development of tubercle in it is at the most only partly true and if used as an argument for leaving the fluid unrelieved longer than it would otherwise have been is mischievous.[2]

The best method of tapping a serous effusion is what is called *syphonage.* The apparatus consists of an ordinary trocar and cannula connected with an indiarubber tube reaching to the floor. The mouth of the tube should be placed in a vessel, say a tumbler, filled with boiled—i.e., sterilised—water so as to avoid the chance of any air being sucked into the chest during the operation. As soon as the needle has been introduced into the side and the trocar withdrawn the fluid flows into the tube and fills it, thus forming a syphon by which the effusion is drawn off under a constant negative pressure of from 18 to 24 inches of water—that is to say, of the height of a column of water reaching from the seat of the puncture to the vessel on the floor. This pressure is sufficient to empty the side or at any rate to remove all that can safely be taken away. What will not flow away at that pressure had better be left. If tapping be performed in this way and the fluid removed slowly under a steady, constant pressure the lung expands gradually as the fluid flows away.

The change in the lung from the conditions of long-standing collapse to one of distension and renewed activity is attended with considerable respiratory and circulatory embarrassment which may even lead to symptoms sufficient to compel the operation to be suspended. These symptoms are pain, cough, shortness of breath, faintness, and general discomfort. The *pain* is usually referred to the sternum or upper part of the affected side and is probably due to the stretching of adhesions there. If the flow be stopped for a few minutes the pain may pass off and some more fluid may be then removed without recurrence. Usually the pain returns and continues to increase, so that the operation has to be terminated. The *cough* may be due to irritation of the surface of the expanding lung by the cannula and then can be obviated by withdrawal of the cannula or the alteration of its direction in the pleura. Cough may, however, be connected with the expansion of the lung and the alteration of the circulation in it or to the presence of some secretion in the larger tubes which accumulated there while the lung was compressed. In these circumstances it may be very severe and paroxysmal so that it becomes impossible to proceed with the operation. The *shortness of breath* is for the most part subjective and if the flow be stopped for a time it passes off and does not return. At other times, though there is no cough, pain, or any special dyspnœa, the patient suffers much *general distress* and becomes anxious and uneasy or even pale and faint. These symptoms are, I think, generally of cardiac origin and depend upon the altered condition of the circulation as the lung re-expands. At any rate, the distress may be sufficient to make it clear that the operation cannot be continued with safety. Usually as the lung re-expands the air enters freely and the respiratory murmur is fairly normal but sometimes towards the end of the operation wheezing sounds and crepitation develop, indicating the exudation of fluid into the air tubes. A considerable quantity may then be expectorated which may be streaked or stained with blood. In its most extreme form the conditions of serous or albuminous expectoration develops, a very rare and remarkable condition which, though alarming, is seldom fatal.

All these symptoms, though they may occur when paracentesis is performed by the syphon, are much more likely to arise when the fluid is removed more rapidly and under much greater negative pressure by the aspirator. For this reason the aspirator should not be employed—it is not necessary and is, moreover, attended with risk. To use the aspirator with the object of sucking the lung out and making it expand is a dange [illegible] for it may cause the lung to rupture and [illegible] or, by the infection of the serous fluid, possibly pyopneumothorax, that is to say, pneumothorax in its most unfavourable form. This risk is no imaginary one. I have seen the lung ruptured on many occasions and knowing what a strain must be put upon the lung I tremble when I see the aspirator used fully exhausted so that the fluid rushes out from the pleura when the tap is turned in a violent jet. Of course, if the lung were perfectly free and could expand uniformly no harm might ensue, but it is impossible to tell that there are not adhesions which will check the expansion of some part of the lung and expose it to a strain which it cannot stand The great difference of pressure produced by the aspirator is shown by the frothing which takes place in the aspirator bottle, the gases contained in the serum being liberated and filling the bottle with bubbles To use the aspirator in this way is like cracking a nut with a sledge hammer It is attended with great risk and no advantage If the aspirator be employed at all it should be kept exhausted only sufficiently to make the fluid flow and even then it should have a manometer attached to indicate the actual pressure which is being employed The *aspirator is, however, quite unnecessary and is better never* used for the paracentesis of serous effusion Syphonage will remove all the fluid that need be removed and is quite safe

---

[2] Further details on these points will be found in my book on "Diseases of the Organs of Respiration," vol. ii., p. 670, &c.

A general *anæsthetic* is quite unnecessary and indeed, undesirable, as it masks the symptoms which show that the operation has gone far enough The trifling pain of the skin puncture can be obviated by applying to the part for an hour or two previously a pad of lint well soaked in a 4 per cent solution of cocaine

Paracentesis may be repeated as often as the fluid reaccumulates but when frequent paracentesis fails to cure the question of further radical measures may arise

Free incision of the side deliberately performed for a refractory serous effusion is rarely required Some few years ago I treated a case in this way in which paracentesis had been performed more than 30 times The patient being highly tuberculous was not a favourable case for such an operation but she made a complete recovery in time It is now many years ago but the chest has been perfectly well ever since and it is difficult to detect except by the scar on which side the operation was performed A second case of the kind I had under my care a year or two later

The objection to this method of treatment is of course, that it necessarily leads to empyema but, as the cases show, this is easier to cure than the recurrent serous effusion The operation should not be performed unless the lung be free from adhesion and able to expand freely and every care must be taken to make sure of this Otherwise a cavity is left in the pleura which it will be difficult to close and the patient might have been better off with that space full of fluid than open to the air and discharging pus Still, the cases which I have recorded show that in appropriate cases this is a method of treatment that is justified by success To recommend free incision as a routine method of treatment of serous effusion into the pleura within a few days of its development is as rational as it would be to lay the knee joint open for a recent simple synovitis Yet this so called radical treatment has been advocated I consider it unjustifiable

II —PURULENT EFFUSION EMPYEMA

When pus is pent up in the body the sooner it is let out the better, accordingly the treatment of empyema is by free incision and rightly Still it is interesting to be reminded that in the days when the operation for empyema was not so simple and successful as it is now many cases were cured by paracentesis The knowledge of this fact

give relief and gain time till the patient is in a better state to stand the incision I can recall many cases both in adults and children in which one paracentesis or more resulted in complete cure and in some it would be impossible now to tell which has been the affected side Of course if paracentesis be performed for empyema the aspirator must be employed, as considerable suction may be necessary to get pus to flow but more suction than is absolutely required should never be used for with every increase of pressure the risk of rupturing the lung increases especially as in such cases the empyema may be already trying to break through the lung and there will therefore be weak spots in it

When incision is to be made the rule which Trousseau laid down should never be departed from—that at the time of operation a needle should be passed first and when the pus has been found used as a director to lead the knife into the cavity It is impossible to be sure beforehand that an empyema is a simple one, often those which from the physical signs seem simple prove to be difficult so that the pus is not easy to find If the pus cannot be found with the needle it will not be found with the knife *Therefore to* pass a needle first should be the invariable rule I have seen failure to find pus with a needle prevent an operation which in the end proved to be unnecessary, as the diagnosis *was wrong, and I have many times found pus with a needle* so deeply seated that no one would have ventured to explore so far with a knife unless the needle had been there to guide it

The seat of incision —Of course, the incision must be made wherever the pus is, but in a case where the choice is open the best place to select is just in front of the post axillary border and on the transverse level of the nipple It need not be farther down, because directly the pleura is evacuated the diaphragm rises and soon reaches that level It need not be farther back because the patient will not lie upon the tube and with the incision in this place he can lie comfortably on the back If the incision be farther back the patient will turn over on to the opposite side and the drainage will be no better than with the incision in the place I recommend

Resection of rib should not be performed as a matter of routine Its object is to provide free drainage If drainage can be obtained without resection is not necessary and an unnecessary operation should never be performed There is no reason why the hole should be round Drainage will be just as good if the hole be oval and two small drainage tubes placed side by side between the ribs are quite as efficacious as one large tube which necessitates resection At the time of operation the pus often contains curdy flakes which are difficult to remove but these curdy flakes are the consequence of the pus having been in the pleura for some time and th the side has been opened Howe d of at the time of operation by e finger and washing the side freely out Of course if resection is necessary it must be done, but it is often unnecessary and should not therefore be considered a routine part of the procedure

Washing out —I cannot discover whence the tradition comes that washing out the pleura is a dangerous proceeding There is no risk in it whatever I have washed the pleura out many hundred times and I have never seen a patient become even faint in the process On the contrary, I should lay down the rule that the pleural cavity ought to be washed out thoroughly wherever the pus is curdy, flaky, or offensive, or contains blood clot, for by this means recovery is greatly accelerated

The mode of cure of an empyema cavity is by expansion of the lung and falling in of the side By these means after incision in a case that has not been neglected or allowed to remain long unrelieved, the cavity may be almost completely obliterated in the course of a few days and nothing be left but the track in which the tube lies There should be no hurry to remove the drainage tube Safety should not be sacrificed to the *desire for brilliancy* *The track of the tube* should close up from the bottom In a simple case the tube may be shortened rapidly and soon can be put in no more But it may happen that if the tube be removed too soon the external opening quickly closes, then pus accumulates behind and either makes its way out through the old incision or this has to be opened with the knife again and a tube re inserted I have seen the desire to whip the tube out too soon result in three or four operations on the same patient for the purpose of putting it back again Not infrequently if a refractory track be examined with a probe it is found to extend back to a pouch somewhere behind where a broken-down gland or some other lesion existed and which presumably caused the original empyema As a rule it may be held that if the tube is not out in three weeks or so it will be necessary to retain it for a long time, possibly months I have seen a case in which a small tube had to be worn for

quires more

r free resec

ainage may

not be free Indeed the tube may itself prevent drainage and sometimes lies actually across the exit from the cavity and closes it By the careful use of a probe it is easy to ascertain exactly what the condition of things is and how to deal with it Whether I have been myself responsible for performing the original operation or not I make it a rule to examine the cavity with the probe every few days and I may say in passing that the after treatment of an empyema is better left to the physician than to the surgeon

Estlander s operation is very fatal and when successful is followed by fearful deformity Now that empyema is recognised earlier and is better treated the cases in which it might be even thought of will be few and far between

Excisions of small portions of three or four ribs, modified Estländer as that has been called, is not an Estländer at all. It is generally of little use. The remarkable cases recently published by Mr. C. A. Ballance show what can be done by a skilful surgeon, but the results are quite exceptional and neither the cases nor the results are likely to recur.

III.—PNEUMOTHORAX.

In pneumothorax tapping may be indicated at two different periods: (1) immediately after its occurrence and (2) later when effusion has formed. Immediately after its occu [illegible] ied to give exit to the air and [illegible] has been produced by the rapid collapse of the lung and the consequent embarrassment of the respiration and circulation. For this purpose the apparatus used for syphonage is sufficient and an aspirator is absolutely unnecessary. If paracentesis repeated several times fails to give relief and urgent symptoms continually recur free incision of the side may be performed. Various forms of valved tubes have been advocated but they almost always lead to incision; so I prefer incision at once as safer and more satisfactory. When effusion has formed, whether of serum or pus, the treatment should be on general lines.

In hydropneumothorax air is readily absorbed but the fluid is under less favourable conditions for removal than when no air is present. Sometimes the air is absorbed and fluid only is left which is removed gradually in the ordinary way, though it may have to be assisted by paracentesis. When air and fluid are present together care must be taken in tapping so that the mouth of the cannula is below the level of the fluid, otherwise the air only and not the fluid will be removed. In such cases the opening from the lung is nearly always sealed and with the syphon there is little risk of opening it afresh but, of course, the aspirator would be extremely dangerous. The prognosis of hydropneumothorax is by no means bad and would be better if paracentesis was performed earlier than it usually is.

Pyopneumothorax is the most serious form but even this may be successfully treated on general principles. It is not the presence of air with the effusion that makes the difference but that both alike are in most cases the result of tuberculous disease of the lung, from which the patients die though they may get well of the pneumothorax.

Tuberculous disease of the lung used to be regarded as conclusive against free incision of the pleura in any circumstances. That is not the view held now in regard to empyema nor should it be either in respect of pyopneumothorax as cases which I have recorded show. Therefore I do not hesitate to lay down the rule that pyopneumothorax should in all cases be treated like empyema—i.e., the side should be laid freely open and drained so soon as the presence of pus has been established. If that be done the results for pyopneumothorax will not be worse than for tuberculous empyema and will certainly be better than leaving the case alone and doing nothing.

The treatment of pleuritic effusion is a subject by no means exhausted, yet, rapid as our progress in recent years has been, our knowledge of the physics of the pleura and the lungs, upon which rational treatment must be based, is very far from complete. If incidentally I have suggested problems which still await solution, or have shown that even in so ordinary a subject there is still much work to be done, the labour of preparing this paper will be amply repaid.

Wimpole street, W.

A CASE OF INTRAPELVIC EXTRAVASATION OF URINE.

By DAVID LOWSON, M.D. ABERD., M.R.C.S. ENG.,
SURGEON TO THE ROYAL INFIRMARY, HULL

THE more common form of extravasation of urine is well known. From blows or kicks on the perineum, falls astride, or rupture of the urethra behind a narrow stricture the urine escapes into the perineal space in front of the triangular ligament and burrowing backwards as far as the transversus perinæi muscle it there finds a barrier formed by the junction of Colles's fascia with the base of the triangular ligament which changes its course and directs it forward and upward. This fascia is attached to the ascending rami of the ischium and the os pubis, rises convexly like a tent, covering the structures filling the perineum, and anteriorly turns outward to join Scarpa's fascia in the groin, thus preventing the constantly increasing flow of extravasated urine from making its way from the perineal space into the thigh and directs it first forward, after filling the anterior half of the perineum, into the scrotum and the penis and then upward into the connective tissue of the anterior abdominal wall, and laterally above Poupart's ligament towards the loins. In most traumatic ruptures the tear is near the junction of the bulbous and membranous portions of the urethra just in front of the triangular ligament, for in several cases in which there has been a large wound in the perineum it has been possible, by passing the finger into the wound and guiding it along the anterior aspect of the triangular ligament, to place the tip on the torn end of the urethra, as it lies in the opening in the ligament and thus to introduce an instrument into the bladder just as one passes a female catheter by touch alone. In other cases the wound is in the membranous portion only, where it lies between the anterior and posterior layers of the triangular ligament. When the urethra is ruptured in this situation, in addition to the urethral tear the anterior layer of the ligament is also lacerated, for the course taken by the extravasated urine is the same as when the rupture is in front of the ligament at the bulbo-membranous junction.

These are the two commonest forms of ruptured perineal urethra and it is seldom that one comes across any other and in both the urine takes a forward course, running superficially the whole way. Should the urethra, however, be torn further back a very different path is pursued by the escaping urine. Such an accident occurred in the case of a young sportsman who was thrown from his horse when hunting on Jan. 12th, 1904. The accident seems to have been undoubtedly a severe one. A gate had been opened for the horses to pass through but as the rider was approaching it swang to and he was obliged to negotiate it at a short distance and at an inadequate pace. The consequence was that the horse did not rise sufficiently to clear the gate and catching its fore-legs on the top bar turned a somersault and came down on its back with great force with the rider underneath. The latter probably came in contact in the sitting posture and the horse following drove the pelvis into the hard chalky ground. Some stone or hard piece of raised soil must have come into violent collison with the perineum and driven it forcibly upwards.

The patient was carried home, a distance of four miles, and Mr. F. Calvert was summoned at 4.30 P.M. the same day. Mr. Calvert found on his arrival that the patient had passed urine half an hour before the accident and that he was complaining of much pain in the back and in the left side of the pelvis and groin. There were no great degree of shock and no symptoms at that time of internal injury. A somewhat restless night followed and on the next morning a catheter was passed as far as possible and a small quantity of blood and urine was drawn off. In the afternoon, accompanied by Dr. J. P. Park of Beverley, Mr. Calvert again visited the patient and again introduced a catheter into the urethra, drawing this time only a little blood. The patient said that he had previously passed water freely while in a bath. From what I saw afterwards I do not think that any urine at all was passed on this occasion but that he simply urinated into the torn structures. At 9 P.M. the same evening I saw the case in consultation with Mr. Calvert and Dr. Park. At the examination no swelling was found in the perineum or the scrotum and neither sign nor symptom of extravasation in the usual situation. Above the pubes, however, there was a large central globular tumour, dull on percussion and extending three parts of the way up to the umbilicus. It was tender to the touch and pressure on it caused an immediate desire to micturate. The lump was tense and semi-fluctuating, and I had little doubt that it was a distended bladder, but all attempt to get an instrument into the bladder proved futile, for on reaching the deep urethra the tip always deviated to the right and there it entered a space where it had considerable liberty of movement on rotation but with the finger in the rectum it could be at once felt that it had never reached the bladder.

The patient was therefore without further delay placed on the table, anæsthetised, and the pubes was shaved and cleansed. On making an incision in the middle line above the symphysis a stream of dark blood and urine poured into the incision and over the abdominal wall. The stream was of about the size and curve of that which flows from a healthy adult urethra. At first the orifice was supposed to be a vein and a clamp was applied but it proved to be an artificial channel hollowed out of the connective tissue and communicating with a reservoir deep in the pelvis. The muscular layer was next divided and we came immediately on the bladder which was undoubtedly distended but not so much as expected. The blood seemed all to come from the right side of the bladder and on passing the fingers in that direction down into the pelvis immediately there welled up a large quantity of blood and urine filling the line of incision and overflowing the abdominal wall coming from a large cavity by the right side of the neck of the bladder. Quite one and a half pints of fluid had to be sponged out of the pelvis and after it seemed empty blood of a brighter tinge still continued to flow. On passing the hand down into the excavation it was clear that it was capable of holding the fluid that had already overflowed and as the bladder was still quite tense and full it was also plain that there was no rupture of that organ. At the bottom was felt the ischial or pubic ramus but quite denuded of all covering; the bare hard bone was there but no line of fracture could be detected by the most careful searching with the finger nail. There is little doubt that when the perineum came in violent collision with the hard projecting earth the floor of the pelvis with the bladder was driven up into the abdomen and the right pubo-vesical ligament and all the soft structures were violently torn off the bone and forced up into the abdomen and that at the same time the pudic vessels were torn across and the urethra being also completely severed just at the tip of the prostate and behind the deep layer of the triangular ligament the blood and urine soon excavated for themselves a large chamber in this situation. Even here the pressure of the fluid was very high for it had channelled out for itself a course through the muscular layer into the subcutanea where it was found in the earlier part of the operation. As there was still bleeding going on the cavity was packed firmly with aseptic sponges. A small opening was next made in the bladder and with the finger inside and a catheter in the urethra the instrument was ultimately insinuated successfully into the bladder and tied in. A piece of indiarubber tubing just fitting the vesical opening conveyed the urine to a receptacle by the side of the patient, the wound was then partially closed and dressed and the patient was placed in bed.

On Jan 14th the temperature was 101° F and the pulse was 118. On the 22nd the temperature reached 103 and the pulse 104. The catheter was on the same day removed from the bladder as well as the tube from the vesical wound. There was considerable pain in the urethra and the glands of the right groin swelled up. This was due to a little pus that had formed in the abdominal wall close to the incision. This was incised on the 24th. Some lymphangitis occurred in the thigh but was allayed by lotions of acetate of lead. After this all went well and the opening in the bladder closed on Feb 19th. Nine weeks after the accident the patient was quite convalescent and his urethra so far has given no trouble. He is a young man of fine physique and there is little doubt that his youth and strength have borne him over a very serious accident.

Hull

PRE MENSTRUAL PREGNANCY IN A GIRL AGED 13 YEARS.

By AUGUSTUS W ADDINSELL M B C M EDIN,
M R C P LOND,
PHYSICIAN TO THE LONDON TEMPERANCE HOSPITAL

A GIRL, aged 13 years was taken to the London Temperance Hospital by her mother early in January last suffering from abdominal pain and slight vaginal hæmorrhagic discharge. The breasts were well developed and contained milk. There was an abdominal tumour. The pubic hair was very slight in quantity. As vaginal examination was extremely painful an anæsthetic was given. It was found that an arm and the cord were presenting. There was no pulsation in the cord. Mr T G Ward, the senior resident medical officer performed version and removed a well developed seven months child which showed no signs of life. Convalescence was without incident.

The interest of this case lies in the fact that impregnation took place before the outward signs of sexual maturity had manifested themselves. The evidence of the mother had been carefully taken, the girl herself was very positive that "she had never seen anything" and remained unshaken when questioned by the medical registrar or by the sister of the ward in private conversation, she was at school and professed entire ignorance of her condition, moreover, she positively denied any intimacy with man or boy.

There is nothing very remarkable in the age of this young mother. Plenty of cases of precocious maternity are to be met with. A girl nine years old, gave birth to an infant in France, others of 11¾, 12 and 12½ years respectively are recorded in this country but in these cases previous menstruation had been noticed. The testimony of the patient and her mother in this instance is so definite as to make it quite certain that the usual monthly flow had never taken place. After all is this very wonderful? The signs of sexual maturity in the female are well known to be development of the mammary glands, growth of pubic hair, and finally menstruation. Whilst these are the outward signs of sexual maturity cellular activity within the ovary has been proceeding regularly since the birth of the individual. A very interesting and instructive contribution towards the study of the fate of the ovum and Graafian follicle in pre menstrual life has been published by Dr T G Stevens in vol xlv of the Transactions of the Obstetrical Society for 1903. He there traces the history of the follicles and the series of changes they undergo together with the fate of the ovum and its ultimate removal by the phagocytic agency of the cells of the membrana granulosa. This cellular activity within the ovary of the female is precisely similar to that which goes on within the testis of the male leading to the development of the spermatozoa.

Now sexual maturity depends for its onset upon a variety of causes climate race, nutrition, growth, &c but there is reason to believe that our remote ancestors matured sexually much earlier and were much more prolific and that with the advance of so called civilisation the recognised nubile age has been made later and later until at the present time it presents a grave sociological problem in more than one European country. In Central Africa it is by no means an uncommon thing for a girl to become a mother before she has menstruated, and in certain districts of India where early marriages are common the same thing has been recorded. Rachmaninoff a Russian physician reports a case in a girl aged 14 years. A traveller in the remoter regions of Australia told me of a case in his own camp of a girl, aged ten years who had never menstruated and became pregnant. Metchnikoff in his book "The Nature of Man" quotes several cases also. In the warmer and Eastern climates then it would appear to be a well recognised fact and this doubtless because there is in those countries less sexual restraint while in the West sexual maturity in both sexes comes later and when it does come environment, habit, training and general oversight make early or precocious impregnation less probable but that is all, precocity in the East is the rule in the West it is the exception.

The life history of the ovum and follicle in pre menstrual life as traced by Dr Stevens shows that maturity up to a point is constantly going on in those follicles which come to the surface and when that point is reached retrograde changes take place in the infantile ovary. Now as the age of sexual maturity is being reached and as ovulation is regularly proceeding it is easy to see how impregnation might occur even though the outward and visible signs of sexual maturity be absent. The periodic occurrence of [illegible] really independent of menstruation and [illegible] and it is not difficult to see [illegible] excitement attendant upon [illegible] at the rupture of a ripe [illegible] the ovum.

Assuming the statement of this patient and her mother to be true (and there is no reason *to doubt it, for every effort* has been made to ascertain the exact facts)—viz, that she had never menstruated—then it is an added proof were that needed, of the contention that ovulation and menstruation are not interdependent though they may be coincidental.

There is something curiously akin to a pathological process in the menstruation of women. In every other instance discharges of blood whether from the intestines lungs, or kidneys, are evidence of disease. The analogue in the higher vertebrates is "heat," but in very few is this accompanied by a discharge of blood, and where there is a slight staining the proportion of red blood corpuscles to white is very small, as in those macaque monkeys observed by Heape of Cambridge. In the case of "Johannah," the famous chimpanzee, whose menstrual history I have recorded elsewhere, I made a careful microscopical examination of the menstrual discharge and satisfied myself that the red corpuscles were comparatively small in number, though enough to tinge distinctly and to stain red the monthly flow; still, all these were under the artificial surroundings of captivity. Not only the attendant pain and copious loss in woman but the general and nervous disturbances occurring at these times are suggestive of a departure from the originally normal line. The amenorrhœa accompanying lactation is often regarded by women as a welcome condition of security from impregnation. This we know to be an error, for ovulation is proceeding with its accustomed regularity and impregnation may, and often does, take place. Furthermore, the development of the endometrium every month may be safely regarded as the preparation of the uterus for the implantation of an impregnated ovum and the menstruation may be considered as evidence of a failure of these anticipations.

It is quite likely that primitive woman never menstruated, at any rate as we know menstruation to-day, and there is reason to believe that this phenomenon, this heritage of woman, of which she is not proud and for which she is not grateful, has assumed its present proportions as a result of the almost universal practice, begun in the earliest ages, of restraining the excessive uberty of our primeval ancestors.

Curzon-street, W.

A CASE OF

CHRONIC INTESTINAL OBSTRUCTION WITH PERFORATION OF THE SIGMOID FLEXURE.

BY GEORGE A. CLARKSON, F.R.C.S. ENG.

THE notes of the following case present one or two points of considerable interest. At the time of the first operation the history and the age of the patient led me to believe that I was dealing with a stricture of some part of the colon due to growth but the distension of the small intestine and cæcum was so great and the call for immediate drainage of the distended bowel was so urgent that no prolonged examination of the colon could be made. The subsequent sloughing and perforation of the sigmoid flexure probably occurred at the seat of obstruction, yet here no cause was obvious to account for the condition found. The gut, though in a condition little short of gangrene, was apparently not invaded by growth and the fact that no fæcal matter was found in it rather excluded the idea that retention of a scybalous mass of fæces at that point had given rise to inflammatory softening and perforation of its coats.

The patient, a woman, aged 52 years, had suffered from disease of the outer surface of the acetabulum for 12 years and the sinuses on the outer side of the right hip had healed after a free exploration and scraping in May, 1903. In the spring of 1904 she began to be subject to occasional attacks of vomiting, accompanied by abdominal pain, distension, and constipation, but these attacks were relieved from time to time by aperients and enemata. On May 9th she was seized with a severer attack than usual. The bowels were at first relieved and the sickness would stop for 12 hours at a time but invariably returned again. The patient was kept in bed, put on a fluid diet, and saline aperients and enemata were given with some result. A rectal examination revealed no stricture within reach of the finger nor could anything be felt through the abdominal walls to localise the seat of obstruction. On the 15th the symptoms became urgent, the vomiting being persistent and copious but not offensive in smell, the abdominal distension became very great, and there was obviously more or less complete obstruction. Enemata given through a long rectal tube produced no effect, so the patient was removed without delay to a surgical home. The operation was carried out in the evening. The abdomen was opened in the middle line below the umbilicus. Enormous distension of the small intestine and cæcum was met with and as the transverse and descending colon appeared less distended and the indication to drain the bowel with as little delay as possible was urgent the wound was closed and another small incision was made over the cæcum, which was drawn out, opened, and a Paul's tube tied in. Following the operation there was a little vomiting of a stercoraceous character but the cæcal opening gave great relief and the acute symptoms subsided. At the end of a fortnight the patient was able to be removed home. Enemata were subsequently given from time to time and occasionally brought away small scybalous masses.

On the afternoon of June 11th the patient was suddenly taken ill with intense pain in the left inguinal region and when I saw her was extremely collapsed, with drawn features, cold extremities, and thready pulse. Subcutaneous injections of strychnine with a little morphine were given and she gradually rallied, symptoms of an acute localised peritonitis quickly manifesting themselves. A diagnosis of intestinal perforation was made and on the 15th an incision similar to that for inguinal colotomy was made over the area of pain and resistance. On opening the abdomen some very foul-smelling pus welled up and the abscess cavity having been thoroughly swabbed out the sigmoid flexure was seen plastered over with thick lymph and with a perforation on its anterior surface of the size of a shilling. The coats of the bowel were softened, black, and gangrenous and in bringing it forward it tore almost across. The wound was therefore enlarged in an upward direction and the bowel was slit up with scissors till its walls appeared unaffected by the changes below and would allow of its being stitched to the skin which was then done. The whole condition seemed to be an acutely inflammatory one. The abscess cavity was again swabbed out and then packed with iodoform gauze, an indiarubber tube of large calibre being passed into the colon.

The patient stood the operation well. The discharge was most offensive for some days but the cavity contracted quickly and at the end of a month the opening differed but little from an ordinary colotomy opening and it acted well. As the cæcal opening became an annoyance to the patient when she began to get about again owing to the liquidity of the discharge, on August 11th, under ether, the mucous membrane was separated from the skin and the opening closed. At the time of writing (March, 1905) the patient finds no difficulty in controlling the artificial anus and she is able to get about out of doors and to resume her ordinary domestic duties at home.

Leicester.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON THE ABDOMINAL INCISIONS FOR THE EXPLORATION OF THE APPENDIX AND PERFORATED ULCER OF THE STOMACH.

BY CUTHBERT S. WALLACE, M.B., B.S. LOND.,
F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS AT ST. THOMAS'S HOSPITAL; ASSISTANT SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN.

The incision for exploration of the appendix.—The two abdominal incisions that are most in vogue for removal of the appendix—namely, that of McBurney and that through the rectus sheath—have their advantages and disadvantages. The McBurney incision is cramped and if difficulties are encountered gives poor access even if strongly spanned by assistants. It is, on the other hand, easily and quickly closed. The rectus sheath incision gives a good view and can be enlarged without difficulty to any extent; it is, however, often difficult to close owing to the tendency of the layers behind the rectus muscle to retract towards the iliac crest. The following modification seems to combine some of the advantages of both incisions. The rectus sheath is entered towards its outer side by the usual vertical incision. The muscle is then retracted inwards and the posterior wall of the sheath is exposed. As a rule two nerves are seen running transversely inwards about one inch apart. The mid-point between these is selected and the peritoneal cavity is entered by an incision one inch long transverse to the body axis and parallel to the nerves This incision is easily closed since the natural tension of the parts approximates the edges Should difficulties be encountered in the removal of the appendix and a large incision be required it can be obtained by the usual vertical incision in the posterior rectus sheath

The incision for perforated ulcer of the stomach —In many cases of perforating ulcer of the stomach or the duodenum it is a matter of doubt as to whether the pelvis has become infected or not Even after the usual epigastric incision the same doubt remains, since the state of the middle area of the abdomen is no criterion as to that of the lower portion The only method of settling the point is by making an incision in the hypogastrium Should this be made after the upper incision there is danger of infecting the pelvis if this prove clean, since hands and instruments are already soiled It therefore seems advisable in cases of doubt to make the hypogastric incision first The state of the pelvis can then be ascertained and if found clean the wound can be closed If the contrary prove to be the case the lower wound can be used in the process of cleansing the peritoneum The primary lower incision is also of service in determining the condition of the appendix when there is doubt as to whether the appendix region or the upper part of the intestinal tract is at fault

Upper Wimpole street W

A CASE OF ACUTE IODINE POISONING WITH FATAL RESULT

By E DONALDSON SIM, M R C S ENG, L R C P LOND,
SENIOR RESIDENT MEDICAL OFFICER AT THE GUEST HOSPITAL DUDLEY

A MAN, aged 52 years, was admitted to the Guest Hospital, Dudley, on the morning of Jan 25th, 1905 with an outward dislocation of the right foot and a simple fracture of the right fibula He had been a hard drinker for some years and was drunk at the time of the accident There was no evidence of definite cardiac disease on examination of the heart and no anasarca was present No specimen of the urine was obtained The dislocation was reduced under chloroform soon after admission On the morning of the 26th the patient showed signs of threatening delirium tremens He was placed on a bromide mixture and of course was on milk diet He complained of pain in the left side of the chest but no sign of injury or disease was found on examination Orders were given however to paint the painful area with liniment of iodine When about to do this (at 7 30 P M) the nurse placed a bottle containing liniment of iodine on the patient s locker and then left the patient for certainly not more than a minute During this short period however the patient seized the bottle of iodine, uncorked it and gulped down the whole of the contents, about four ounces I was in the ward at the time and hearing the other patients call out I turned round in time to see the patient replace the empty bottle on the locker I at once took steps to wash out the stomach but in order to do this we were forced to anæsthetise lightly the patient with chloroform The stomach was then thoroughly washed out until the returning boric lotion was quite clear On completion of this operation the patient promptly regained consciousness, his pulse was good and his condition seemed satisfactory There was no dyspnœa nor was there vomiting or purging In about an hour s time the pulse became very feeble the extremities were cold and blue and the face was cyanosed respiration was easy but the patient kept expectorating and complained of some pain in the epigastric [illegible] tion of strychnine were injected [illegible] in two hours as there was no [illegible] tles were applied and one ounce of brandy was given per rectum Two drachms of bicarbonate of sodium were given by the mouth in a little water and diluent drinks were ordered In spite of treatment, however the patient died from cardiac failure at 11 45 P M The coroner unfortunately, did not order a post mortem examination to be made

The case is of interest on account of the rarity of acute iodine poisoning and on account of the rapidity with which death followed the swallowing of the poison in spite of energetic treatment Probably this was partly due to the patient having been in a low condition of health on account of his drunken habits

POPLAR HOSPITAL

A CASE OF SEROUS PLEURAL EFFUSION FOLLOWING ACUTE RHEUMATIC ARTHRITIS AND PERICARDITIS

(Under the care of Dr CECIL WALL)

FOR the notes of the case we are indebted to Mr A C Dixon house physician

A man aged 44 years, was admitted into the Poplar Hospital under the care of Dr Cecil Wall on August 19th 1904 The patient had been ill for 14 days with acute rheumatic arthritis There was nothing of importance in his previous history or in his family history, he had not previously suffered from rheumatism On admission his temperature was 102 4° F , many joints were hot, red tender, and swollen, and there was much sweating The heart was not enlarged but a systolic murmur was heard at the apex and in the axilla accompanying a weak first sound He was put on full doses of salicylate of sodium and the temperature fell rapidly and reached normal on August 22nd On the 23rd the temperature rose to 100° and loud to and fro pericardial friction was heard, during the next few days the temperature continued to rise and reached the maximum of 104° on the 29th Between these two dates a large pericardial effusion developed and the patient became delirious After the 29th the temperature began to fall and the pericardial effusion to lessen On Sept 6th the area of cardiac dulness was only slightly larger than normal but for some days the temperature remained between 100° and 101° On Sept 7th and 10th the patient had syncopal attacks from which he recovered under the influence of stimulants Between the 6th and the 15th the pyrexia continued, there was a good deal of diarrhœa and the patient sank into a typhoid state Tested on Sept 14th the blood did not give Widal s reaction On the 13th signs of pleurisy at the right base developed and an effusion formed of which 29 ounces were evacuated on the 16th A report upon this fluid is appended The temperature now gradually fell to normal and on the 20th there was no evidence of pleurisy or of effusion on the right side Pleural friction, however, was heard in the left axilla At the beginning of October a fresh effusion formed in the right pleural cavity and 11 ounces were removed by aspiration on Oct 4th The signs however, at the right base persisted and the temperature again rose An exploring syringe was again inserted on the 21st but only three ounces of fluid were obtained After this the signs cleared up, the temperature became normal, and the patient made rapid progress towards recovery He was discharged to a convalescent home on Nov 22nd On discharge and when seen about a month later the heart seemed a little enlarged but no murmurs could be heard In all other respects he seemed perfectly well

Report on the pleuritic fluid by Miss H L B[illegible]TT *of the Laboratory of Pathology and Public Health* —'Microscopical examination of the centrifugalised deposit from the fluid showed it to consist chiefly of red blood discs, with a fair number of leucocytes and a small number of endothelial cells The blood discs are of good colour and the *leucocytes appear to be chiefly of the polymorphonuclear type* The coagulum shows a similar composition with the addition of fibrin *No tubercle bacilli* have been found in a stained specimen Plate cultivations were made from the centrifugalised deposit and an organism was isolated which is similar in microscopical appearance to the rheumatic diplococcus, appearing in pairs, groups and short chains. This was inoculated into various media; a characteristic fine growth was seen on the solid media, and the production of acid was noted in most of the liquid media, with a sedimentary growth. It does not liquefy gelatine; this organism is thus seen to correspond in many respects with the characters of the diplococcus of acute rheumatism."

Report on the fluid obtained on Oct. 4th by Dr. C. E. HAM, *chemical pathologist to the London Hospital.*—"The following is a report on pleural fluid sent to me on Oct. 5th. Colour: very pale straw; specific gravity 1018; reaction to litmus very faintly alkaline. Chemical examination: proteid (albumin and globulin) about 1·5 per cent. and a substance which reduced Fehling's solution slightly. No formic acid and no lactic acid could be detected. Microscopically practically nothing was seen under oil immersion except a few leucocytes."

Remarks by Dr. WALL.—It is generally accepted that rheumatism may cause pleurisy but it is less commonly held that it may lead to the formation of a clear pleural effusion. In this case bacteriological evidence supports the clinical diagnosis. Dr. G. A. Gibson, in a lecture published this year,[1] says that he is not aware of any case of pleural effusion from which the microcroccus of rheumatism has been isolated. I have not myself been able to find a report of any such case and consequently think that this instance is worthy of record.

DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

A CASE OF RUPTURED KIDNEY AND LIVER; OPERATION; RECOVERY.

(Under the care of Mr. K. W. MONSARRAT.)

A MAN, aged 28 years, was admitted on Nov. 26th at 3 P.M. to the Northern Hospital immediately after an accident in which he had been crushed between a wagon and a wall. The patient was very pallid, breathing heavily. His pulse was slow (66 per minute) and he was complaining of great pain in the abdomen. There were no external marks of injury. Palpation of the abdomen revealed nothing, being extremely painful and resistant, but on percussion marked dulness in the left flank was elicited and palpation there caused considerable pain. A catheter was passed and the urine was found to contain blood. Rupture of the left kidney was diagnosed. The pulse-rate increased steadily after admission. At 4.15 P.M. two pints of normal saline solution were injected intravenously previously to operation.

Under ether an oblique incision was made in the left flank, just below the ribs; blood was present in the perinephric tissue. An irregular laceration two inches in length was found on the anterior surface of the kidney at its superior pole; this was stitched up by means of three silk sutures. The peritoneum was incised to the outer side of the descending colon, whereupon a quantity of blood and clots escaped. The hand was then introduced into the peritoneal cavity and the spleen was explored and found to be normal. The hand was then passed across the abdominal cavity and a laceration of the liver was discovered. The lumbar wound was closed, a glass drainage-tube being passed down to the kidney. An anterior incision below the ribs on the right side exposed the liver. The laceration was found on its anterior surface, four or five inches in length, ending on the anterior border about one inch to the outer side of the gall-bladder. Another small tear was present on the anterior border external to the former. The blood and clots were removed as far as possible from the peritoneal cavity and the laceration was packed with gauze; it was not sutured. The parietal incision was closed by through-and-through sutures of silk-worm gut and the gauze packing was brought through its upper extremity. Two pints of normal saline solution were injected intravenously and a quarter of a grain of morphine and $\frac{1}{100}$th of a grain of atropine sulphate were administered hypodermically before the patient left the table.

On the next day the patient had not quite recovered from the shock and the collapse. The wounds were dressed and the glass tube to the kidney was replaced by rubber drainage tubing. The gauze drain was removed from the liver as hæmorrhage appeared to have ceased. Atropine sulphate ($\frac{1}{100}$th of a grain) was given hypodermically every three hours. On Nov. 28th one grain of cocaine was given every hour because of severe vomiting. Five grains of calomel having been given without result an enema of gruel and turpentine was ordered. The atropine was discontinued and strychnine (four minims every four hours) was substituted. The pulse was feeble, the face was flushed, and the pupils were dilated. The patient complained of a great deal of pain over the wounds. On Nov. 29th another gruel and turpentine enema was given with an excellent result, the general condition being decidedly better in consequence. Blood was now absent from the urine. On Dec. 2nd the condition had greatly improved, except for a superficial skin infection of both wounds, for which boric foments were applied every four hours. By Dec. 16th the patient was well on the way to recovery, complete restoration to health being delayed by the complication already referred to.

Remarks by Mr. MONSARRAT.—The chief complaint made by the patient on admission was agonising pain across the back at the level of the upper lumbar spines. During exploration of the kidney blood was seen to be present in the peritoneal cavity and the peritoneum was incised. Through this incision the spleen, the liver, and the other abdominal organs were examined with the hand and the long tear in the liver was felt with the fingers. Hæmorrhage from the tear in the liver was readily checked by gauze packing; in addition to the large wound there were several smaller wounds, only one of which, however, involved the peritoneal covering.

Regarding the indications for operation in such a case, in my opinion where definite signs of rupture of the kidney are present operation is always advisable. Agonising lumbar pain is usually present in a characteristic manner in contusion and rupture of the liver and in this case the signs of hæmorrhage into the peritoneal cavity were sufficiently distinct.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Some Experiments in Connexion with Stimulins.—Demonstration of Cultural Forms of the Leishman Body.

A LABORATORY meeting of this society was held at the Royal Army Medical College, Victoria Embankment, on March 21st, Sir JOHN BURDON SANDERSON, the President, being in the chair.

Major W. B. LEISHMAN, R.A.M.C., described a series of experiments demonstrating the Property possessed by Typhoid and Malta Fever Sera of stimulating the Phagocytic Power of Leucocytes derived from Normal Blood towards the Bacillus Typhosus and Micrococcus Melitensis respectively. The first series of experiments were conducted *in vitro* by Major Leishman's original method of quantitatively estimating the phagocytic power and demonstrated that the addition to normal blood of a very small amount of immune serum, whether derived from a convalescent patient or from an immunised animal, increased the phagocytic power of the normal leucocytes to a very marked degree. The addition of a similar amount of normal serum or of serum derived from men or animals immunised with other germs had either a negative or an inhibitory effect upon phagocytosis. This stimulating effect was found to be exercised only in the case of the particular germ which had been employed in immunisation. It was further shown that the stimulating properties of these sera were not destroyed or diminished by heating to 60° C. for 15 minutes. In another series of experiments the modification of Major Leishman's method employed by Wright and Douglas in their work on opsonins was adopted. In these the normal corpuscles were freed from the citrated plasma by centrifugalisation and repeated washing in normal salt solution and all the sera subsequently added to these washed corpuscles had been previously heated to 60° C. for 15 minutes. In this way the thermo-labile opsonins, if present in these sera, had been destroyed and the possibility of the stimulin effect being, in part or altogether, due to opsonic action was excluded. In this series immune sera derived from a case of enteric fever and from a rabbit immunised with bacillus typhosus were found to exhibit stimulating properties similar to those of the sera

---

[1] Brit. Med. Jour., Jan. 7th, 1905.

tested in the first series In a further experiment an
was made to determine whether the increased phag
following on the addition of the immune serum was
the action of the serum upon the bacteria or was caused by a direct stimulation of the leucocytes In this experiment the emulsion of living germs employed was divided into three equal parts the first was digested for one hour at 37° C with heated typhoid serum the second was similarly treated with heated normal serum while the third was untreated The germs which had been digested with the sera were then freed from these sera by washing and suspended in normal saline solution A parallel series of experiments was conducted with these three emulsions The results appeared to show that the stimulins acted directly upon the leucocytes The above experiments were then contrasted with those previously described by Metchnikoff Gengou, Besredka and others but as the latter were conducted *in vivo* upon animals whose peritoneal fluid or exudates were withdrawn and studied accurate comparison was not possible Major Leishman however concluded that the stimulating action demonstrated in his experiments was due to the presence in the immune sera of the 'stimulins described by Metchnikoff and others He pointed out however that he had obtained no evidence of any stimulating effect from the addition of normal serum such as had been described by those authorities The conclusions which he drew were, first that sera derived from cases of typhoid or Malta fever or from animals immunised with living cultures of these organisms appeared to contain a substance—stimulin—capable of stimulating normal phagocytosis Secondly these stimulins were specific—i e they only induced increased phagocytosis of the germ which had been employed in immunisation Thirdly they were thermostable withstanding a temperature of 60° C for 15 minutes Fourthly no evidence of a stimulin effect was obtained from the normal serum of man or animals Fifthly although their action might possibly be reinforced by that of the agglutinins or the immune body they were not identical with either of these substances Sixthly they appeared to act by direct stimulation of the leucocytes

Major LEISHMAN then gave a demonstration of the Cultural Forms of the Leishman Body He showed a series of microscopic specimens illustrating the changes which these parasites undergo in artificial culture eventuating in the development of a flagellated organism closely resembling a trypanosoma (The original cultures were obtained by Captain J C B Statham R A M C at Netley)

CHELSEA CLINICAL SOCIETY

Chronic Constipation and its Medical and Surgical Treatment

THE annual clinical debate of this society was held at the Chelsea Dispensary Manor street King s road London on March 14th Dr F VINCENT DICKINSON the President being in the chair

Mr W ARBUTHNOT LANE in opening the debate on Chronic Constipation and its Medical and Surgical Treatment first described the conditions of the viscera consequent on imperfect evacuation of the large bowel In the large majority of cases such a condition was associated with the symptoms properly comprehended under the term constipation , in a small proportion of cases however the patient might have a daily evacuation but might still have a loaded large bowel The sufferer might obtain from the overflow of the loaded large bowel a daily action which was usually solid but might be fluid and consequently there might be no complaint of constipation When children were fed unsuitably the intestines and particularly the large bowel might become distended with gas rendering the whole of the abdomen abnormally prominent The cæcum and the ascending colon appeared to suffer most severely and the transverse colon became distended and elongated in a downward direction as a consequence Mr Lane then referred to a paper which he had published in August 1893 in which he called attention to the presence of fluid associated with distension of the intestines resulting from malnutrition the large bowel becoming more or less inflamed sufficient to produce a distinct peritonitis as manifested by the effusion The appendix shared in the inflammatory process and might do so sufficiently to become attached in the position in which it

r

come

considerably elongated by the forcible downward displacement of the cæcum in consequence of the development of that organ and its elongation from distension by its contents Such fixation of the appendix might not give rise to any obvious symptom but it left the organ more or less damaged functionally and capable of becoming obstructed and acutely inflamed at any time Appendicitis was in the first instance directly consequent upon the condition of distension and inflammation of the cæcum at some period or other excepting those rare cases where a foreign body was the cause Appendicitis therefore, practically never existed except as a consequence of the overloading of the intestinal cesspool and must of necessity have been associated at some time or other with the results of such distension The forcing down of the cæcum and transverse colon was much helped by the sedentary position assumed almost universally during defæcation in civilised communities The inflammation of the cæcum and the ascending colon consequent on their excessive distension produced an adhesive process between the outer wall of the bowel and the peritoneum with which it came into contact The sigmoid flexure was driven down and obstructed and ultimately might become so contracted up in consequence of the adhesive process that it ceased to be a loop and formed a straight conduit One most conspicuous clinical symptom was a fulness and tenderness in the region of the cæcum which organ in the erect and sitting posture in these cases of any severity reached well into the true pelvis Most pain was felt when the cæcum lay upon a firm background such as the iliac fossa or pelvic brim The tenderness extended upwards to the hepatic flexure and pressure on the loin below the last rib caused pain partly due to the strain exerted upon that area by the loaded bowel when the trunk was in the erect position and partly due to the thrusting in an upward and backward direction of the upper limit of the ascending colon As the transverse colon became frequently adherent to the ascending colon the area of the tenderness of the one merged into that of the other The patient was liable to attacks of pain in the region occupied by the inflamed and dilated cæcum and such attacks were frequently mistaken for inflammation of the appendix alone In consequence the appendix which might or might not be inflamed was frequently removed for the relief of such conditions of acute distension the patient however after such operation obtaining only the temporary relief that was afforded by the prolonged assumption of the resting posture which was favourable to the emptying of the intestinal cesspool and by the care and attention which his bowels received during the period of convalescence When such a patient again resumed the erect posture he soon complained again of the troubles from which he suffered before his appendix was removed That condition of the large bowel was almost the only cause for the pain which the patient experienced after these unsuccessful appendicular operations excepting such conditions as might be due to an incorrect diagnosis in the first instance That in Mr Lane s opinion was exactly what might be

causation of disease of the
removal of the appendix
patients of their painful
and no array of statistics

pointing to a contrary conclusion to that could be relied upon It was possible at the time of operation to gauge fairly accurately the amount of success that would follow upon the removal of an appendix and if necessary upon the division of such bands as might be constricting the lumen of the cæcum and of the ascending colon or hitching up and obstructing the hepatic flexure Mr Lane observed that the failure to relieve permanently these patients of their symptoms in a number of so called cases of appendicitis was forcing itself daily more and more convincingly upon the profession and was calling forth a more thorough study of the physical conditions which produced appendical inflammation and which were associated with it It seemed to him that the consulting physician and the general practitioner could help the surgeon most materially by giving an account of their experiences of the subsequent history of these cases after operation In certain cases of chronic constipation the patients referred all the pain to the epigastrium or to the umbilical region and the many symptoms comprised under the term indigestion might be present in an aggravated form. Mr. Lane then explained in detail the symptoms due to the absorption of toxins tending to produce an appearance in the patient of premature senility and described how the skin became dry, thin, and loose, the secretions acquiring a nasty offensive smell in the flexures. One of the most conspicuous consequences was the loss of fat and once that commenced it afforded the best indication that the patient was going rapidly downhill. In considering the question of treatment he did not propose to deal with any form other than operative, since he assumed that everything short of operative interference had been tried. When it became apparent that something must be done beyond drug and other such treatment the question resolved itself into whether an attempt should not be made to liberate the bowel by the division of bands or adhesions or whether it would not be better to establish direct continuity between the lower end of the ileum and the termination of the large bowel. In regard to the operative procedure itself Mr. Lane explained that he divided the ileum about six to eight inches from the cæcum and then connected the proximal end with the sigmoid flexure or rectum. The operation was simple and the results were excellent provided the case had not been allowed to drift on till adhesions and dilatation of the small intestine had occurred and considerable dilatation of the stomach had taken place. Many had objected to the operation on the assumption that the patient would afterwards be affected by persistent chronic diarrhœa. Such was not the case, for in a large proportion of the cases the patients had still for some considerable time to take drugs or by preference use glycerine enemata.

The PRESIDENT said that the remarks made by Mr. Lane forcibly reminded them that the treatment of chronic constipation did not consist alone in the giving of aperient drugs and, apart from its surgical treatment, its cure was not to be found in any one panacea. He then proceeded to give a brief survey of the causes of chronic constipation. The causes of chronic constipation might be primarily divided into two groups, intrinsic and extrinsic. Intrinsic causes might be further divided into: muscular atony, glandular atony, hepatic inefficiency, chronic colitis, and mechanical causes, organic and functional. The President discussed these seriatim and in the course of his remarks mentioned that small doses of castor oil seemed to act better than any other therapeutic measure in relieving constipation and curing the disease. By small doses he meant ten minims every four hours or a drachm night and morning and it might usefully be combined with belladonna. Kussmaul introduced the injection of olive oil into the colon as a cure for that complaint, from three to ten ounces of warm olive oil being employed every night at bedtime which should be retained during the night. In order to effect that, the oil should not be injected through a Higginson's syringe but by means of a douche can suspended above the bed and connected with a nozzle and indiarubber tube of large calibre. After a time the injection might be used on alternate nights and the patient would probably find that he obtained an evacuation each morning; the intervals could be then lengthened until cure was effected. He also pointed out that an excess of lime salts in drinking water was one of the most important of the extrinsic causes of constipation. He thought, too, that lack of sugar and lack of water might perhaps play a subsidiary part in the causation of chronic constipation, for some people drank too little water or fluid of any kind. The President concluded by saying that in the future the cure of constipation might be effected by surgery rather than by medicine but until that happy time arrived there would be many who would echo the words of mine host of the Garter Inn set forth in the *Merry Wives of Windsor*: "Shall I lose my doctor? No; he gives me the potions and the motions."

Dr. W. H. GODDARD said that on the existence or non-existence of the pathological processes described by Mr. Lane depended the argument in regard to chronic constipation. Dr. Goddard said that for the last three years he had had considerable experience in cases of chronic constipation and had been present at many surgical operations undertaken for its relief. He had seen the conditions described by Mr. Lane and considered his conclusions logical and correct, for they were borne out by the success of the surgical methods which he advocated. The treatment initiated by Mr. Lane was not universally accepted by his brother consultants; indeed, one eminent consultant had given denial categorically to Mr. Lane's teaching and method. When Dr. Goddard read that gentleman's statement he was much exercised in his mind to know what his objections could be and after careful reflection he came to the conclusion that that authority had attributed, rightly or wrongly, such advantageous functions to the colon that it would be unjustifiable to interfere with it. That conclusion led Dr. Goddard to ask himself, What then were the functions of the normal colon? Continuing, Dr. Goddard stated that he had been experimenting in Paris during the last few months on the living colon of the dog and the rabbit. He set himself to determine those functions under four heads: 1. As to the peristalsis of the colon. Was it peculiar to the colon? 2. As to the digestion of fat carried on by the agency of bacteria known to abound in the cæcum. 3. As to the absorption of fluid from the fæcal mass. 4. As to the digestion of cellulose. He would briefly describe his experiments. He purged both a dog and a rabbit and administered to them A.C.E. mixture. When the abdomen was opened he made a small incision in the posterior part of the ascending colon and through it he passed a small indiarubber ball to which was fitted a tube fitted with a stop-cock. The elastic ball was chosen in consequence of its collapsibility, so that it could be passed through a comparatively small orifice and also because it could be easily inflated and deflated to suit the altering calibre of the large gut. He noticed that the wall of the intestine contracted on the ball and it was not difficult to see that both the external longitudinal and the internal circular muscular coats contracted together at the same instant of time. To make sure of that particular, however, he applied an enterograph which confirmed his observation. He also observed (in the case of the rabbit the intestine of which was more delicately responsive than that of the dog) that in front of the ball there was a contraction of the intestinal wall and so marked was this that it might be compared to a constrictor or sphincter. The combined effects of these two processes were evidently to insure a twisting or churning movement on the ball. After a time the sphincter gave way and the ball was carried upwards or onwards, only to meet with a repetition of the process at the hepatic flexure of the intestine and then again in the middle of the transverse colon but he could not follow its action further. The text-books told them that first one coat of the intestine and then the other contracted but it was clear they contracted together, the outer or longitudinal muscular coat acting as an adjuvant to the inner coat by pressing tightly upon it. As to the digestion of fat, he fed a dog on diet containing a slight excess of fat of known weight. He obtained the fæces arising from this food. He boiled the fæces first in alcohol and subsequently in ether, the ether was evaporated off from the product, and the fat and other compounds soluble in ether were weighed. He then removed the ileum of the same dog from its normal position and implanted it into the upper rectum. When the dog had recovered from the operation he administered to it a diet exactly similar to what it had previously received in its normal condition. He found on weighing the fat resulting from its fæces that the average quantity of six experiments was 12 per cent. more than in the first experiment, hence 12 per cent. of fat was digested by the cæcum. Concerning the absorption of fluid from the fæcal mass, in the last experiment it was noted that during the first 15 days after the operation the fæces were passed in a liquid condition, resembling the fæcal fluid mass normally found in the ileum. But subsequently to that period the fæces gradually regained their normal consistency. In regard to cellulose, he regretted to say that his experiments were not yet completed but he thought that they might accept the conclusion of the German agricultural chemists—viz., that cellulose was digested by the large intestine. Those, then, were the functions of the large intestine of the dog and of the rabbit and he presumed that they might in a great degree reason from the colon of the dog to that of man. Although they had seen the large intestine to possess great functions and great advantages he could not conceive them to be very great. Indeed, he believed that did the necessity arise life could be maintained without it—that man could live without a colon. Let them consider what exactly would be their loss. Its peristalsis? No; for it would not be required. Loss of fat? 12 per cent. of the whole amount digested was not a great loss, even if they omitted the possible presumption that the small intestine might even in some degree do the work of the large intestine in that respect just as occurred in the case of the absorption of fluid when the large intestine was rendered functionless Absorption of fluid from the fæcal mass? No, for they had seen in the dog and indeed, in man that after a certain lapse of time the small intestine became equal to that task Digestion of cellulose? Yes, but cellulose did not largely enter into their diet and it was by no means a necessary part of it Therefore they might say there would not be any great loss If man could live without his normal colon he certainly could do so in the ca

found the colon was

at all they must be

its very slight aid to the human economy was more than counterbalanced by that one fact—namely that in chronic constipation they had a portion of the colon the cæcum acting as a cesspool where the fæces were stagnating and undergoing chemical decomposition and producing toxic substances which enter into the blood stream and sap the vitality of the patient and speedily send him to his grave He supposed general practitioners would rather attempt the treatment of chronic constipation by drugs and other methods than by surgical operation Drugs might be useful in that class of cases of chronic constipation which had not yet led to structural alterations within the abdomen and into their treatment he did not purpose to enter but however efficacious the medicines they employed he thought the majority of even those cases would sooner or later exhibit pathological changes and given pathological structural changes drugs could avail nothing Indeed they were worse than useless, for they delayed the surgical operative measures which in the end must be adopted Hence in the manner he described operative interference was now the only method remaining

Mr J F PALMER said that they welcomed a radical treatment *of chronic constipation in certain cases* as suggested by Mr Lane which would in a degree restore the normal condition of the parts and practically enable the patient to begin his intestinal life afresh, and then was the time for the medical man to impress upon his patient the importance of cultivating the necessary habits of regularity to secure success in overcoming the trouble In regard to therapeutic measures Mr Palmer advocated warm water and warm olive oil per rectum either alone or both together He suggested that people should eat enough both in quantity and variety and should drink in proportion for a sufficiency of fluid was of the first importance He described the beneficial effects of belladonna and gave details of the action of nux vomica

After Dr SEYMOUR TAYLOR had addressed a few words to the meeting the debate was adjourned to March 21st

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION

Exhibition of Specimens —Discussion on Nasal Obstruction and Mouth Breathing

A GENERAL meeting of this society was held on March 10th at the rooms of the Medical Society 11, Chandos street W Mr W J CHICHELE NOURSE the President, being in the chair

The PRESIDENT said that the illuminated address which was to be presented to Señor Manuel Garcia was on view It consisted of a border and lettering in the Italian style of the sixteenth century with two miniatures—one in the initial representing Music and the other in the medallion at the foot depicting Orpheus playing to the beasts The work was designed and executed on vellum by Mr Charles Randal

Dr SAMUEL BRADFORD showed a case of Excision of the Superior Maxillary Bone for Epithelioma of the Antrum in a boy

Dr V H WYATT WINGRAVE showed a case of Paralysis of the Left Vocal Cord in a youth aged 20 years

Dr ANDREW WYLIE showed a case of Papilloma in the Larynx under treatment by the galvano cautery

A discussion then took place on a paper which had been read at a previous meeting by Dr J SIM WALLACE on Nasal Obstruction and Mouth Breathing

Dr HARRY CAMPBELL said that the chief point in the paper seemed to be Dr Wallace's firm belief that the diet of children was at present too soft The jaws were therefore *insufficiently* exercised and in consequence of this the maxillary apparatus as well as the adjacent chambers of the nose *and the* naso pharynx failed to develop properly, another result of this faulty dietary being that indigestion was set up and this led *secondarily to inflammation in the* nasal cavity, *the naso pharynx, and the tonsils* With these two propositions Dr Campbell declared himself to be in complete agreement and said *that if the* nasal chambers did not develop properly there would obviously be a predisposition to *nasal obstruction* He further suggested that the rhythmical contraction of the pterygoid muscles must tend to stimulate the flow of blood in the naso pharynx and that deficient exercise of these muscles must lead to stagnation of blood and lymph in the naso pharyngeal mucous membrane which was thereby predisposed to disease Children who were *improperly fed* also had a tendency to suffer from intestinal sepsis and thus an unhealthy condition of the alimentary tract was set up bacteria abounded, and the absorption of poisons produced by them as well of abnormal digestive products brought about a chronic toxæmia One of the results of that toxæmia was a diminished power of resistance to disease and a tendency to inflammation of the mucous membranes—a condition which might be called the catarrhal diathesis These children were very likely to suffer from enteritis bronchitis pharyngitis and rhinitis Rhinitis thus induced was a potent factor in nasal obstruction, especially when the nasal passages were ill developed in consequence of the insufficient use of the jaws Adenoids in children he attributed also to the causes already mentioned—namely sluggish circulation in the lining membrane of the naso pharynx and irritation of it by blood charged with toxic products derived from the intestines Primary nasal obstruction in children and the nasal obstruction secondary to adenoids were therefore both of them essentially dietetic conditions

Mr MAYO COLLIER said that he could not altogether agree with the etiology of mouth breathing as explained by Dr Wallace and Dr Campbell He did not think that malformations of the upper jaw and palate in children were due to the nature of their food In India, China and other parts of the East there was a population of at least 400 000 000 persons who he was credibly informed, from the time of birth until they were laid in their graves never consumed anything but rice curry, and fruits, and if that were so it might be expected that the most exaggerated examples of malformations of the upper jaw and destructive conditions of the teeth would be found amongst them Instead of the causes assigned by Dr Wallace and Dr Campbell he thought that something else must be looked

believed would be found in

which in its broad applica

hen it was considered that children were born with perfect upper and lower arches, that their palates were flat like a dessert spoon, that the nasal chambers were well formed and that the jaws had never been used at all, the inference was that there must be some distinct and emphatic cause why things went wrong in after life The alterations in the palate and mouth which were being discussed were not found until the individual attained 10 or 15 or even 20 years of age In a paper which he read eight or ten years ago as a result of the examination of some 1050 cases, he pointed out that distorted upper jaws and deflections of the nasal septum were extremely rarely found before the age of ten years His idea was that the whole of those changes were due to what might be called mal assimilation and liver incompetence Those soft foods, such as bread and milk, which were spoken of by Dr Wallace as being improperly given to young children in place of less digestible and less easily swallowed foods were preparations which contained much albuminous and saccharine material and this required a large amount of oxidation The result was that in the tissues there was collected an immense amount of material which was gout producing and half oxidised Those children were found to suffer not only from catarrh in the nasal passages but from eczema in various parts of the body, diarrhœa bronchitis, and a multitude of other infantile complaints His opinion was that the troubles in the nose and post nasal space were due to toxæmia caused by the half oxidised products floating in the tissues This toxæmia set up a vaso motor paralysis in the nose and the back of the throat and was followed by catarrh which lessened the nasal respiration and that lessened nasal respiration caused a diminution of oxidation whereby the toxæmia was increased. In that way there was a vicious circle produced. With oral respiration there was increased pressure on the palate and upper jaw and the deformities which followed were a direct consequence.

Dr. **B. H. SCANES SPICER** said that in conjunction with Dr. Campbell he had examined a large number of skulls in the Museum of the Royal College of Surgeons of England for the purpose of seeing if the vaulted palate could be detected in the older crania of civilised and savage races, but he did not think that there was a single case of vaulted palate to be found there, a fact which showed that the prevalence of that malformation, now so common in England, was a comparatively modern phenomenon. After referring to the position of the respiratory current in the nose, he mentioned Mr. W. Arbuthnot Lane's theory in connexion with the causation of nasal obstruction and adenoids. In this theory the results in question were attributed to respiratory toxæmia from imperfect oxygenation of the blood causing chronic infection of the respiratory mucosa. He believed that Mr. Collier was the first to suggest that negative air pressure in the respiratory tract was a factor in the production of adenoids. Mr. Collier had always dwelt on the extreme variations of pressure in forced breathing as of especial valency in etiology but he (Dr. Scanes Spicer) was inclined to dwell on the minor differences in manometric pressure between ordinary inspiration and ordinary expiration. He believed that comparatively slight but lifelong variations of pressure exercised more influence in producing (through the medium of suction) congestion behind the obstruction and secondary hyperplasia than those violent variations of pressure which only occasionally took place. In a paper read before the Odontological Society some years ago on the nasal factor in the etiology of vaulted palate he attributed the condition mainly to the arrested development of the nose from disuse in respiration and to the fact that the septum was not pushed down or the sinuses expanded, but he now thought that the modern disuse of the jaws was the more powerful factor, although arrested nasal development had some effect.

Dr. **G. A. SUTHERLAND** said that the food given during the first two years of life among the better classes was far too soft and fluid, but among the poorer classes this was not so, for their children as soon as they were able to chew were given food from the family table. Therefore he did not recognise soft food as a cause of nasal obstruction in the poorer classes, among whom it was nevertheless known to be extremely common. He heartily agreed with Dr. Wallace's view that nasal troubles were the result of chronic indigestion and his (Dr. Sutherland's) opinion was that the chief factor in that indigestion was over-feeding.

Dr. **WYATT WINGRAVE** said that in connexion with mouth breathing and nasal obstruction there was a great necessity for coöperation between the rhinologist and the dental surgeon. Children might be confirmed mouth breathers suffering from spasmodic dyspnœa and different varieties of cough, but on examination it would be found that they sometimes had no adenoids whatever, that the nostrils and the naso-pharynx were small, and that the choanæ would scarcely admit the end of the little finger and that the palate had the shape of a typical Gothic arch. These cases were extremely unsatisfactory to rhinologists because nothing could be done for them beyond using palliative remedies and it would be a great advantage if the coöperation of the dental surgeon could assist in enlarging the nasal and naso-pharyngeal cavities. He could not agree with Dr. Wallace's view that adenoids were caused by nasal obstruction. Adenoids were embryonic vestiges which might undergo enlargement under certain physical conditions, of which nasal obstruction was probably one, but it was not a primary cause of the condition. With regard to the origin of the Gothic arch palate and crowded denture, it was possible that septal distortion and consequent nasal obstruction might be secondary to the Gothic arch.

Mr. **JAMES WIGG** said that in the case of the infant food was often allowed to remain in the inside much too long and he supported the idea that toxæmia or gout was a very potent cause of trouble in children.

Mr. **E. DENNIS-VINRACE** said that if that society could suggest to the school boards what was the most efficient diet for the children it would render a very important service to the nation.

Dr. **WYLIE** spoke in deprecation of the modern system of sending children to school at three or four years of age and said that if school attendance did not commence till some years later there would be less nasal obstruction.

Dr. **WALLACE**, in reply, said that he had been much interested in Dr. Campbell's suggestion of toxæmia. It seemed to emphasise the idea of the relationship between the congested state of the naso-pharynx when there were corresponding pathological conditions of the alimentary canal. With regard to Mr. Collier's remarks as to the conditions of people in Eastern Asia, the food and the feeding of aboriginal peoples had been a subject of great interest to him for many years, and in the cases in which a trustworthy and accurate account of the food had been got it had shown that the conformation of the jaw and the wearing of the teeth corresponded to the amount of mastication which the food stimulated or demanded. There was once a discussion in THE LANCET on the matter in which it was contended that the kafirs in South Africa lived almost exclusively on soft mealie pap. When investigating the matter he had some of that mealie pap sent from South Africa and he found that it stimulated vigorous mastication, although it was made in the form of porridge. It had the same effect even if it were boiled for an hour or two and the effect was similar to that when one ate nuts. It was difficult to swallow nuts until they were finely comminuted and so it was with mealies. Over and above this he had found in Ratzel's "History of Mankind" that five kafirs could devour an ox in one and a half days, eating sinews, entrails, and everything. He investigated some other cases in which it was said that the rice was softened as we softened it. But in China, for example, it was not cooked soft but each grain was whole and separate and the consequence was that when taken into the mouth it stimulated mastication. Moreover, when once a child had got into the habit of masticating he could not swallow without that mastication. Chinese children were given quantities of sugar cane which could not be swallowed. The child sucked and chewed it but the fibrous part was not swallowed; thus the child learnt to separate the fibrous part which was not swallowed from the juices which were sucked and swallowed. Consequently at an early age the Chinese child learnt to masticate his food.

EDINBURGH OBSTETRICAL SOCIETY.

Anti-cancerous Serum.—Lumbar Puncture in Eclampsia.—Malta Fever in Pregnancy.—Heredity in Ovarian Cystoma.—Etiology of Uterine Fibroids.

A MEETING of this society was held on March 8th, Dr. **N. T. BREWIS**, the President, being in the chair.

Professor **A. R. SIMPSON** showed a patient on whom he had used Doyen's Anti-cancerous Serum for Cervical Cancer. The uterus was removed by vaginal hysterectomy. Five injections were given in two weeks before the operation and five after. It had a marked effect in loosening and clearing up the surrounding parts. He also showed a placenta with a cord only three inches long; the cord ended in the membranes about six inches from the placenta and the vessels coursed separately over the membranes to it.

Dr. **J. W. BALLANTYNE** read notes of a case of Eclampsia in which Lumbar Puncture was performed. The patient was a primipara, aged 25 years, and at about the sixth month of pregnancy. Two days before her admission to the Maternity Hospital she was seized with severe and constant pain in the loins. Next day she had a fit, evidently eclamptic, followed by seven others during the night. On her admission to the hospital next morning she was partly unconscious, her temperature was 101° F., and her pulse was 104 per minute and of high tension; the fœtal heart sounds could not be heard. The urine contained granular and hyaline casts and blood corpuscles; it had 2·6 grains of albumin to the ounce and four grains of urea to the ounce. She was treated with hypodermic injections of normal saline solution under the breasts; half a grain of morphine was given subcutaneously and on occurrence of the fits chloroform was administered. Afterwards bromide and chloral mixture was given, also acetate of potassium. The urine increased to 52, 60, and 65 ounces per day but fits again recurred. On the seventh day after admission the spinal canal was twice tapped but on both occasions only a few drops of clear fluid came away. There was nothing like the gush of cerebro-spinal fluid which some observers had described. As labour had evidently commenced it was hastened by the use of a Barnes's bag and Bossi's dilator. There were no more fits. Jaundice set in and became more and more marked, in the end being intense, the pulse became weaker and intermittent, and death took place on the tenth day after admission. Blood counts showed that the leucocytes decreased from 28,000 per cubic millimetre on admission to 13,400 on the fifth day and then gradually increased to 41,900 on the day of death; the red corpuscles showed a decrease from 6,020,000 on admission with 80 per cent. of hæmoglobin to 3,730,000 with 54 per cent. of hæmoglobin on the day of death. The necropsy showed that the liver was undergoing a general fatty change, most marked at the periphery of the lobules; and the kidneys exhibited well-marked chronic parenchymatous nephritis. Lumbar puncture was performed in the hope that by drawing off some of the cerebro-spinal fluid the tension which was considered to be the cause of the fits would be relieved and time thus obtained for other forms of treatment to remove the source of the trouble.—Professor SIMPSON, Dr H. M. CHURCH, Dr. JAMES RITCHIE, Dr. J. HAIG FERGUSON, Dr. J. LAMOND LACKIE, and the PRESIDENT made remarks.

Dr. BALLANTYNE read another paper on a case of Malta Fever in Pregnancy. The patient was 25 years of age and was resident in India when the fever first began. At that time she was four or five weeks pregnant. At the commencement of the fever she suffered from lassitude, constipation, slight enlargement of the spleen, and pyrexia. The temperature rose to about 103·5° F. each evening and fell to normal in the morning. The rise began about noon or 1 P.M. Quinine was administered to the extent of from 25 to 30 grains in the 24 hours but as it caused nausea and vomiting it was next given as intramuscular injections even to the extent of over 40 grains in 24 hours. As this had no discernible influence on the course of the fever the patient's blood was examined and the serum was found to react to the Malta fever test. The quinine was stopped and the patient was advised to take the voyage home to England. Arsenic was tried with but little effect but the temperature became less and afterwards the fever would often be absent for a week or ten days. Along with this improvement the constipation began to yield; at first it required large doses of powerful purgatives to produce even a mild action. Six months after the onset of the fever the blood was again ex- [illegible] it no longer reacted to the Malta [illegible] plicated by the [illegible] set in at the normal period and was of an ordinary character; the child was healthy and well nourished. The case was noteworthy from two facts, one of which was the administration of large doses of quinine both by the mouth and intramuscularly without any oxytocic symptoms, and this in a patient free from malaria. The other fact of importance was that the attack of Malta fever lasted for six months and the temperature was above 103° every evening for six weeks and yet the pregnancy not only progressed satisfactorily but was followed by a normal labour and puerperium, and the child was healthy. G. Levi[1] records 11 cases; in six of these abortion occurred and five pregnancies went to full term with one child stillborn. In only two were the children healthy and in these the fever had attacked the mother late in pregnancy.

Professor SIMPSON read a paper on Heredity in Ovarian Cystoma, illustrated by the history of its occurrence in a mother and two daughters. One daughter, aged 25 years, was operated on in November, 1899, and both ovaries were removed for multilocular cysts, the right ovary, which was the larger one, having its pedicle twisted four or five times. Before the operation this patient had borne two children, one being aged two years and the other four months. Another daughter, aged 19 years and unmarried, was operated on in December, 1902, and both ovaries were removed. The right tumour was formed by one large cyst with some smaller cysts and a healthy portion close to the pedicle; as the left ovary was enlarged and cystic it was removed at the same time. The mother, aged 60 years, had had ten children and was 15 years past the climacteric; she was operated on in February, 1905, for a multilocular ovarian cyst of the right side; the left ovary presented the usual appearance of a healthy senile ovary and it was not removed. Dr. Lever, in Guy's Hospital Reports for 1855, gave a list of seven women, all related, who were the subjects of ovarian disease but the relationship was not stated. Sir James Y. Simpson in his Clinical Lectures stated that he knew of three sisters in a family all affected with ovarian tumours. Dr. John Rose, in THE LANCET of Dec. 22nd, 1866, stated that there were two sisters in the Kidderminster Infirmary with ovarian dropsy and that their mother and another sister had the same. Olshausen had mentioned the cases of two pairs of sisters where the disease was unilateral. Veit, von Winckel, and Pozzi also supported the hereditary disposition. Löhlein had related the history of three sisters who had all been operated on for proliferating cystomata of both ovaries. Martin also had observed two similar examples. As it was the germinal layer that was the seat of the disease the degeneration of this layer involved lessened power of reproduction, so that the married women who suffered from ovarian cystoma were barren in the proportion of 1 in 3 instead of 1 in 9 in the general community. The very development of the disease thus lessened the chances of its descent to another generation.—Dr. BALLANTYNE, Dr. F. W. N. HAULTAIN, and the PRESIDENT made remarks on the paper.

Dr. MALCOLM CAMPBELL read a paper on Pathological Conditions of the Ovaries as a Possible Factor in the Etiology of Uterine Fibroids.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Hysterical Chorea.—Aneurysm of the Innominate Artery.—Pneumonia in Pregnancy.

A MEETING of this section was held on March 3rd, Sir J. W. MOORE being in the chair.

Dr. JAMES CRAIG exhibited a case of Hysterical Chorea in a girl 22 years of age. There was no neuropathic family history obtainable. She was in good health and was occupied as a laundress until two years ago, when she found herself unable to write on account of a shaking in her right hand. The shaking then extended to her head. At the present time she had a rhythmical rotary tremor of the head, coarse in character, particularly when she was under observation, but at times much finer and frequently not to be [illegible] fac[illegible] in [illegible] weakness of muscles were not observed. There was an absence of any of the other manifestations of hysteria and there was no evidence of any organic disease of the nervous system. Rhythmic hysterical spasm was the better name for the condition as the term chorea was misleading.

Dr CRAIG also contributed a short paper on the further history of a case of Aneurysm of the Innominate Artery, reported by him in 1898. The patient had recovered from the aneurysm of the innominate artery, but seven years from its onset he had died suddenly at Wiesbaden from the rupture of an aneurysm of the aorta which was of the size of the head of a newly born child and had ruptured into the œsophagus.—Dr. J. A. MATSON said that the occurrence of perforation into the œsophagus was interesting; out of 68 cases reported by one observer only one had terminated in that way. He had had under his care a case in which perforation into the œsophagus had taken place.—Dr. W. J. THOMPSON said that about six years ago he showed before the pathological section a specimen taken fr[illegible] He was very steady and [illegible] trouble. Death was [illegible] the mouth. The necropsy showed the presence of an aneurysm, of the size of a walnut, situated in the aorta about two inches above the cardiac end of the stomach. It had perforated into the œsophagus. There was no atheroma or disease of the heart.

Dr. H. C. DRURY read a paper on Pneumonia in Pregnancy, illustrated by three cases which he had met with. These were all in the seventh or eight month of pregnancy. The first had double apical pneumonia, the second double basal pneumonia, and in the third the right lower lobe was alone affected. In all three the pregnancy terminated during the disease, the children were alive up to or after birth, though death occurred soon after. When labour was completed the pneumonic symptoms appeared to be relieved and the three intervals ever since. The second patient was a man aged 26 years. He was known to have had a cord-like structure in the neck since early childhood, but up to two years ago it gave him no trouble. It was now a complete branchial fistula which discharged by an external opening about half an inch above the right sterno-clavicular articulation in the line of the anterior border of the sterno-mastoid muscle. The internal opening was in the right palatine arch.—Dr. J. Kerr Love showed a case of Otomycosis (myringomycosis aspergillina). There had been middle-ear discharge for many years but the present disease was of very recent origin. The case was unusual in that the fungous mass occupied the middle ear instead of, as usual, the inner end of the meatus externus. The fungus was found to be aspergillus niger or nigricans.—Mr. A. E. Maylard exhibited a specimen of Lympho-sarcoma of the Neck and Dr. John Anderson showed microscopic sections of the same. The patient was a man aged 24 years. The disease began as a lump on the left side of the neck six months ago. A mass of the enlarged glands weighing one and a quarter pounds was removed about six weeks ago and already there was a large growth in the same position.—Dr. John H. Teacher showed various specimens and cultures from a case of Anthrax occurring in a man aged 32 years. The entire duration of the disease was only 18 hours. It began with indefinite feelings of malaise, then headache developed followed by delirium, unconsciousness, and, near the end, convulsions. Clinical examination revealed nothing but slight tenderness of the epigastric region. At the necropsy small ulcers were discovered in the stomach and intestines and the bacillus anthracis was found in them and in certain of the mesenteric glands which were enlarged and hæmorrhagic. There was a large almost diffluent "septic spleen." The pia arachnoid was the seat of a diffuse hæmorrhage, universal in its distribution but most marked over the vertex of the cerebrum and on the cerebellum The micro-organisms swarmed in the extravasated blood and interstices of the pia mater. In the blood within the vessels they were few in number. The nature of the infection was confirmed by cultures and inoculation of animals. The patient was a paint-grinder and the source of the infection could not be determined

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Liverpool on March 17th, Dr. D. Lloyd Roberts being in the chair.—Dr. A. J. Wallace showed a New Instrument described as an "elevating vaginal director," designed to facilitate the making of a vaginal drainage incision from the abdomen. This was an improvement upon the operator's finger as it could be inserted in the vagina by an assistant, who could then push up the posterior fornix to the level of the abdominal incision. Dr. Wallace also gave the clinical features of a case of Inoperable Carcinoma Uteri with Symptoms of Bulbar Paralysis, and Dr. W. B. Warrington described the post-mortem findings and showed sections of the affected portions of the central nervous system. He mentioned that secondary carcinoma in the brain was very rare and that none was found in this case. Thrombosis of the cavernous sinus completely accounted for the paralysis of the third nerve but there were no gross or microscopic lesions to explain the bulbar symptoms. These, he thought, must be attributed to the state of toxæmia produced by the advanced malignant disease.—Dr. Lloyd Roberts showed a Fibromyoma of the Ovary, the parenchyma of the organ being stretched over one portion of the tumour, the other and larger portion of which had a peritoneal covering derived from the broad ligament. Such tumours were rare and were liable to be mistaken for uterine fibroids. The indications for operation were menorrhagia, pain, and the probability that the growth was malignant.—Dr. A. W. W. Lea read a paper on Tuberculous Disease of the Fallopian Tubes and gave an analysis of eight cases treated by removal of the affected organs. He described caseous, fibrous, and purulent types and regarded the condition as more common than was generally supposed. The removal of the tubes usually permitted of a good prognosis; it was not necessary to remove the ovaries unless these were actually diseased, nor was it necessary to remove the uterus as this could be done subsequently should it prove desirable. The paper was illustrated by numerous lantern slides of microscopic sections.—Dr. S. Buckley emphasised the importance of careful pathological diagnosis.—Dr. G. W. Fitzgerald preferred to operate by the vagina and to remove the uterus along with the diseased appendages.—Dr. H. Briggs agreed that the condition was more common than was supposed.—Dr. H. Armstrong, on the strength of 20 years' post-mortem records, confirmed the rarity of ovarian tuberculous disease.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held at Birmingham on March 15th, Mr. E. W. Wood White, the President, being in the chair.—Dr. J. Douglas Stanley showed a case of Intrathoracic Growth.—Dr. C. E. Purslow showed a specimen from a case of Irreducible Prolapse of the Uterus. The patient, the wife of a labouring man, was admitted to hospital on June 4th, 1904, with a large mass protruding from the vulva which had not gone back for six months. The vagina was completely everted and the uterus lay entirely outside the body; near the centre of the posterior vaginal wall was a small aperture from which a little pus exuded on pressure and into which a fine probe could be passed about one inch. Attempts at reduction under anæsthesia after the patient had rested more than a week in bed entirely failed and so the uterus with a large portion of the posterior vaginal wall was excised. The operation was rendered difficult by the bladder being unusually adherent to the anterior wall of the uterus and by chronic inflammatory thickening of the vaginal wall, the portion of the latter on the specimen showing a thickness of at least one inch. The left ovary was found to be converted into an abscess cavity and to be communicating with, and discharging through, the small hole already mentioned in the posterior vaginal wall. The patient made a good recovery and since the operation had been able with the aid of a ring pessary to get about and to perform her ordinary work. The parts shown were the uterus with the vaginal wall attached and the left ovary.—Mr. A. W. Nuthall showed a specimen of Intussusception.—Dr. J. W. Russell read a paper on Paroxysmal Abdominal Pain associated with Symptoms of Epilepsy.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 9th, Mr. W. Horton Date, the Vice-President, being in the chair.—Mr. C. E. Bell read Notes on a case of Removal of an Enlarged Prostate by Operation.—Mr. A. C. Roper read an exhaustive paper on the Clinical Aspect of Cholelithiasis.—In the discussion on the above Dr. H. Davy, Mr. Horton Date, Dr. Harris, Mr. Russell Coombe, Mr. E. J. Domville, and Dr. R. V. Solly took part.—Mr. Bell and Mr. Roper having replied, the proceedings terminated.

Reviews and Notices of Books.

Manual of Gynæcology. By D. BERRY HART, M.D. Edin., F.R.C.P. Edin., F.R.S. Edin.; and A. H. FREELAND BARBOUR, M.A., B.Sc., M.D. Edin., F.R.C.P. Edin., F.R.S. Edin. With 12 Lithographs and 359 Coloured illustrations and woodcuts. Sixth edition. London and Edinburgh: W. and A. Johnston, Limited. 1904. Pp. 736.

SOME seven years have elapsed since the appearance of the last edition of this well-known text-book and the time had therefore come when a good deal of revision was required. The authors have carried out this work very carefully and conscientiously and we notice many additions in various chapters. It is a pity that the opportunity was not taken to replace some of the original rather poor illustrations, such as those representing solid tumours of the ovaries, by better and more modern drawings. In the consideration of the diagnosis of tuberculous peritonitis the recommendation made by Kelly is quoted—namely, that the fine lines of the adhesions should be looked for and an attempt made to start peristalsis of the intestines by a smart tap with the finger. The authors apparently do not believe that much good is likely to result from opening the abdomen in cases of malignant peritonitis and they recommend tapping only. In support of this view the statistics of Estor and Puccle are quoted. Of 372 cases collected by them 28 per cent. died as the result of operation and of those who recovered 59 per cent., had recurrence usually within a year's time, while in only 3·2 per cent. of cases of carcinoma and 12 per cent. of cases of sarcoma was there a prolonged survival. It is interesting to compare the account given of pelvic hæmatocele in this edition and in the last and to notice the very important part now assigned to the various forms of extra-uterine gestation in the causation of this accident. It is difficult to realise that so great a change in our views of the pathology of this subject and in the treatment adopted could have taken place in the last seven years.

Considerable additions have been made to the section *dealing with the operative treatment of diseased tubes.* The authors are in favour of the abdominal route rather than the vaginal one in operating on these cases. The classification adopted by Pfannenstiel in his article on ovarian tumours in Veit's handbook is that given—viz., (1) tumours arising from the stroma of the ovary; (2) those arising from the parenchyma; and (3) combination tumours. Wilms's theory as to the origin of dermoid tumours is quoted as the most probable and, as the authors point out, unless we accept such a theory it is impossible to explain how entodermic structures are met with in these tumours, although it is so difficult to understand what stimulus should make a primordial ovum undergo such a change, analogous as it is to the condition known as parthogenesis. A new section is devoted to the very interesting group of tumours known as adenomyomata of the uterus. The great progress made of late years in the technique of the various operations performed for the removal of the uterus the seat of fibroid tumours has enabled the authors to compress considerably their description and consideration *of the different methods employed.* The account of the operation of supravaginal amputation with extraperitoneal treatment of the stump has been eliminated and the fact that such an operation was still described in the last edition shows only too clearly the necessity for the appearance of a new edition of this work. The question as to whether the whole uterus should be removed or whether the cervix should be left behind is not discussed, as the view is taken that every case of fibroid tumour must be treated on its own merits and that no general rules of treatment can be laid down for all the different conditions which may occur.

It is a pity that in the revision of this edition the authors did not correct the statement on p. 522 that deciduoma malignum is an ordinary sarcoma modified by pregnancy is the opinion still held as to this condition by some of the members of the Obstetrical Society of London. The discussion on the admirable paper read by Teacher before that society on June 4th, 1903, showed that this is far from being the view held by the majority of the members at the present time. The book still maintains its original characters and is one of the best of the English text-books on gynæcology. The only criticism that it is necessary to add is that the accounts of the symptoms of the various diseases tend to be rather sketchy and are not given sufficient importance.

An Outline of the Theory of Organic Evolution. By MAYNARD M. METCALFE, Professor of Biology in the Women's College of Baltimore. New York: The Macmillan Co. 1904. Pp. 204. Price $2.50.

IN a comparatively small book of some 200 pages Professor Maynard M. Metcalfe of the Women's College in Baltimore has contrived to condense the story of organic evolution. This achievement may unhesitatingly be described as a very successful one, the result being due to the following causes; in the first place the author has a very pleasant and easy style of writing; in the second he has provided for the illustration of his subject an unusually liberal allowance of coloured and uncoloured plates; and in the third place he has carefully steered his way through that vast mass of detailed evidence on which depends the proof of the theory of organic evolution. The task which Professor Metcalfe has performed with such conspicuous success is no doubt a very much easier matter to-day than it would have been a few years ago, when few others than trained men of science accepted the doctrine of organic evolution as based on any more substantial foundation than questionable hypothesis. The main premisses of organic evolution are to-day accepted by a large section of the public, so that in preparing a popular treatise on the subject the author can address himself to a sympathetic audience. Technicalities of all kinds have been avoided and any intelligent reader will be able to follow the general line of argument without undue effort. In a large number of instances the pictures speak for themselves and tell their own tale without further explanation in the text.

The theory of organic evolution is explained in Part I. and is considered from the point of view of natural selection, sexual selection, segregation, and the inheritance of parental modifications. These various factors in the progressive evolution of the organic world are freely illustrated by examples derived from both animal and vegetable kingdoms. The manner in which the offspring tends to resemble the parents, the reasons for variation from the parental type, and the destruction in the struggle for existence of those individuals who are not adapted to their environment are clearly explained in the opening chapters. Under the heading of "Sexual Selection" the author shows how the exercise of choice in mating is a primary stimulus for the development of courting habits and the perpetuation of those conspicuous colours, ornamental appendages, and other attractions which are not only pleasing to the opposite sex but which also add to the general sum of human happiness.

In Part II. the observed facts in variation both in the animal and vegetable kingdoms are explained and interpreted by the several operative factors in evolution. A very considerable proportion of this part of the work is devoted to the explanation of the manner in which colour variation is of value as a means of protection. The manner in which mimetic colouration is utilised as a means of aggression is also graphically demonstrated by a series of very beautiful coloured plates. To many readers the short chapter which is reserved for Man in Relation to Evolution is likely to prove one of the most interesting chapters in the book; it represents a short and popular account of some of the most interesting portions of Huxley's and Romanes's larger works; in fact, it bears the same sort of relationship to these classical works that Lamb's "Tales from Shakespeare" bear to the original plays of the great dramatist.

In every way this little volume is to be regarded as a most fascinating account of the natural history of evolution and the only sense of regret that is likely to be felt by more advanced students than those to whom the book is obviously addressed is that it does not take into its purview the evolutionary changes which run a parallel course in the so-called inorganic world.

LIBRARY TABLE.

The Influence of Growth on Congenital and Acquired Deformities. By ADONIRAM BROWN JUDSON, M.D., Orthopædic Surgeon to the *Out-patient Department*, New York Hospital. Profusely illustrated. New York: William Wood and Co. 1905. Pp. 276.—In this volume certain features are presented in a new light which gives them importance as matters that will repay close attention in practice. Among the subjects thus treated are: the application of the weight of the body for the reduction of club-foot, the use of the equine position of the foot to increase the length of a shortened limb, the adoption of symmetrical movements and correct rhythm for removing deformity and excluding lameness, and the manner in which misleading "tumours" are produced by the rotation of lateral curvature. The author emphasises what seems to lie at the base of orthopædic practice, the fact that prevention and cure are to be found in so managing a case and equipping a patient that natural growth will be the principal factor in recovery. The methods of diagnosis, prevention, and treatment advocated are recorded as having proved useful "and as likely to be at least suggestive in the practice of others." The book is very practical and the questions discussed are made clear; to this end the copious illustrations are exceedingly helpful. The index is very full. The book deserves to become popular as a manual.

A Magisterial Handbook. By W. H. FOYSTER, Solicitor and Notary Clerk to the Justices of Salford. London: Effingham Wilson. 1905. Pp. 75. Price 2*s.* net.—The title page of this little book bears a sub-heading which describes it as "a concise outline of the everyday functions of magistrates with tables of offences and matters cognisable by them" and the description is not inapplicable to it. Whether, however, any useful purpose can be served by the tracing of an outline so extremely concise, or to use an epithet more appropriate to the metaphor so "sketchy," is doubtful. There are a sufficient number of text-books which summarise the duties of magistrates and if they are of a somewhat bulky nature no justice of the peace need carry one of them in his pocket. He uses them when in court, where he has a table or bookshelves upon which they may repose when not in actual use. Mr. Foyster's handbook, in seventy-five by no means closely printed pages of large type, gives information which might convey to a foreigner some knowledge of our criminal law with regard to petty offences or it might serve as an analysis to be read over by a student in the hours immediately preceding his examination. Beyond supplying with some precision the maximum penalty for offences over which magistrates have jurisdiction it conveys but little with which the average citizen is not sufficiently familiar for everyday purposes. Even a "concise outline" should contain more than this if it is to be of any practical utility to laymen; for lawyers such a work can hardly be intended.

Urban Police and Sanitary Legislation, 1904. Being a Collection of Provisions contained in the Local Improvement Acts obtained by English Urban District Councils in the Year 1904, after Consideration by the Police and Sanitary Committee of the House of Commons. Compiled and arranged by FRANK NOEL KEEN of the Middle Temple, Barrister-at-Law. London: P. S. King and Son. 1905. Pp. lxxxv.-240. Price 10*s.* 6*d.* net.—In the session of 1904 the Police and Sanitary Committee of the House of Commons had before it 22 Bills, 11 of which, promoted by municipal corporations and by urban district councils, became local Acts conferring upon them enlarged powers for the government of their boroughs and districts. Mr. Keen has collected, collated, and classified under appropriate headings the provisions of the 11 local Acts of Parliament referred to so far as they relate to the regulation of the matters usually defined as "police and sanitary," excluding the other topics dealt with in local Acts of this character, such as street works, lighting and water undertakings, finance, and the acquisition of lands. The Acts selected do not include those promoted by municipal corporations or by the London County Council. The work of the compiler is intended to be a guide to Parliamentary draftsmen and others concerned with the preparation of Bills of the class indicated and to enable these to compare and to select sections and phrases from measures which have been approved and are therefore suitable for adoption as standards for future local legislation. No trouble has been spared in arranging the precedents in such a manner that a model section already embodied in a recent Act may be considered almost at a glance, together with the material or verbal differences distinguishing from it corresponding sections in similar Acts. The ample tables and index contained in the volume should meet the needs of all interested in the professional study of the subject dealt with and should save for all concerned much time, trouble, and research in discovering, as well as in consulting, the necessary authorities.

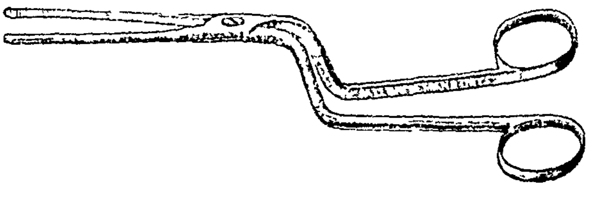
JOURNALS AND MAGAZINES.

Dublin Journal of Medical Science.—The March number opens with a paper by Dr. E. J. McWeeney on a case of chronic lymphæmia which was interesting in that the bone marrow showed no tendency to lymphoid transformation, as well as owing to the fact that an intercurrent attack of pneumonia produced no polynuclear leucocytosis or diminution in the number of lymphocytes present. Mr. R. E Matheson, Registrar-General for Ireland, continues his analysis of the returns of the recent census as applied to Ireland, pointing out among other things a marked decrease in the percentage of illiteracy but also showing that Ireland heads the list in its proportion of deaf-mutes and of insane persons, Scotland coming next, and England last in each category. Dr. Samuel Synge contributes some notes upon Chinese medicines and Dr. J. Francis Dixon discusses a case of chorea insaniens associated with pregnancy.

New Inventions.

FORCEPS FOR NOSE AND THROAT WORK AND FOR OPENING PERITONSILLAR ABSCESS.

THESE forceps are a slight modification of Lord Lister's sinus forceps. Being intended chiefly for nose and throat work they have been made with a crank handle, so that the field of operation is not concealed by the surgeon's hand. It will be found that greater precision and firmness in manipulation are thus secured by being able to manœuvre in a direct line. The extremity is sufficiently blunt not to injure healthy surfaces, but is fine enough to allow of its being pushed through œdematous, necrotic, or membranous tissues. The inner surfaces are roughened so as to permit of grasping foreign bodies in the nose, calculi in the tonsil crypts, &c. I have found these forceps useful for a variety of purposes,—as ordinary nasal dressing forceps, for introducing gauze packing into the accessory sinuses during or after operation, for exploring the sphenoidal sinus, for swabbing the pharynx or treating the tonsils, for seizing the end of the hypertrophied uvula, and so forth. They are also serviceable for packing the wound after the mastoid operation. They will be found particularly useful for opening peritonsillar abscesses. When the abscess is pointing—generally above and external to the tonsil—pressure with the extremity of the forceps will readily detect the site of suppuration and with slight increase in force the point can easily be made to penetrate the abscess. In withdrawing them the two blades should be separated so as to enlarge the opening, as in Hilton's method. These forceps have been in use for several years and are made by Messrs. Allen and Hanbury, Messrs. Mayer and Meltzer, and other manufacturers.



Queen Anne-street, W. STCLAIR THOMSON, *M.D. Lond.*

THE LANCET.

LONDON: SATURDAY, MARCH 25, 1905.

Señor Manuel Garcia.

ALTHOUGH it has been said by some physiologists, we hardly know with what degree of accuracy, that 100 years would be the proper age of man in these latitudes, the actual attainment of that age is still sufficiently uncommon to excite wondering remark. Its attainment by a philosopher whose work has been eminently beneficial to his race is necessarily still more remarkable, even if only by reason of the small numerical ratio borne by such men to their fellow creatures, and it need, therefore, be no matter for surprise that all civilised countries were united on Friday, March 17th, in doing honour to Señor MANUEL GARCIA on the occasion of the 100th anniversary of his birthday. Not only Spain, the land of his birth, and England, the land of his adoption, and Germany, which has contributed so much to the advancement of laryngology, but even Russia and Japan were represented on the occasion and turned for the moment from the realities of war to offer their tributes of laurel to the man who had achieved one of the great victories of peace. The KING, with the graceful and kindly tact which renders him an unfailing exponent of the best feelings of his subjects, initiated the proceedings of the day by conferring the Commandership of the Royal Victorian Order upon the venerable father of laryngoscopy; and this was followed by his investiture by the Spanish Chargé d'Affaires with the Royal Order of ALPHONSE XII. From the German EMPEROR he received at the same time distinction even more marked than any which Royal orders can confer, in the shape of the "great gold medal for science," hitherto bestowed only upon Professor VIRCHOW, Professor KOCH, Professor EHRLICH, and Professor MOMMSEN, while the offerings and addresses presented to him by the scientific bodies and societies of the world were almost uncountable. The last of them, a portrait painted by Mr. SARGENT, R.A., and subscribed for by international contributions from the many personal friends of Señor GARCIA, was a gift which brought the proceedings of the morning meeting held in his honour to a fitting close.

The scene of the ceremonial being in England it is hardly needful to say that a dinner was necessary to its entire completion and this dinner afforded to Sir FELIX SEMON, who proposed the principal toast, an opportunity of sketching the career of the guest of the evening and of describing the successive steps by which he was led to the discovery that the larynx might be rendered visible by a combination of mirrors and that the actions of its several parts in phonation might thus be studied. When Señor GARCIA was occupied, said Sir FELIX SEMON, with the solution of the great problem of the production of sound in the human larynx his scientific mind was forced to the conclusion that facts ought to be substituted for the hypotheses which were in vogue in the middle of the last century and that facts could only be ascertained by inspection of the healthy living larynx when engaged in the act of singing. He was unaware that the problem had occupied the attention of medical minds for nearly a century and that although none of his predecessors had found the solution, some of them, notably AVERY, and BABINGTON, who succeeded in obtaining a glimpse of the glottis in 1829, had not been far from doing so. It was only after many years of thinking upon the subject that one day in 1854, when strolling in the Palais Royal, GARCIA saw in his mind's eye the position of the mirrors which would render the larynx visible; and, as he has himself described in a charming fragment of autobiography, he rushed into the shop of CHARRIÈRE, the well-known instrument maker, and bought for six francs a dental mirror which had been one of the failures of the London Exhibition of 1851. Having procured a hand-glass he hurried home, warmed the little mirror, placed it in his own throat below the uvula, threw the rays of the sun upon it by means of the hand-glass, and on his first attempt had the immense satisfaction of seeing his own glottis wide open. The results of his observations were presented to the Royal Society in a paper entitled, "Physiological Observations on the Human Voice," which was published on March 22nd, 1855, the birthday of a discovery which was destined to revolutionise our knowledge of the larynx in health and disease. How far the former knowledge has been of practical utility in Señor GARCIA's own profession, how far, that is, it has conferred upon teachers of singing and elocution increased powers of training the vocal organs of their pupils or of preserving them from erroneous methods of phonation, it is somewhat beyond our special province to inquire, but at least we have not been made acquainted with any discoveries in this direction which are at all comparable with those bearing upon the investigation and treatment of disease. It cannot be doubted, of course, that a teacher of philosophical mind would render his experience in the highest degree fruitful, and no one can question that Señor GARCIA's many illustrious pupils, among whom JENNY LIND, MATHILDE MARCHESI, JOHANNA WAGNER, ANTOINETTE STERLING, the Misses MACINTYRE, ORRIDGE, LARCOM, and THUDICHUM, JULIUS STOCKHAUSEN, BATAILLE, and CHARLES SANTLEY were mentioned by Sir FELIX SEMON at the dinner, would be of one mind in the conviction that the benefits which they had derived from his instruction would be incomparably greater than any which would have been likely to accrue to them from teaching based upon tradition or "experience" alone. Such benefits, great as they presumably were, and eminently conducive to the enjoyment of countless audiences, must still be looked upon as subordinate to the application of the invention along lines which the inventor himself was not qualified to pursue, the lines of medical and surgical discovery and manipulation.

From this aspect of the question we think it is somewhat to be regretted that no endeavour seems to have been made to associate the great name of CZERMAK with the honours of the day. GARCIA is not more incontestably the father of laryngology as a whole than CZERMAK is the father of its applications to the study and the treatment of disease, applications which, it will be remembered, were made early and extensively in this country. The instrument itself was improved by Czermak who brought it to London during the course of the great exhibition of 1862 and gave many demonstrations to the profession. He revealed for inspection and treatment many previously unsuspected forms of throat disease and not only enabled surgeons to see and to remove growths springing from the vocal cords but also disclosed certain forms of paralysis to which the cords are exposed, sometimes from disease of the brain, sometimes from pressure upon their nerves by aneurysms and other swellings within the chest. All branches of the medical profession may unite cordially with musicians in doing honour to the philosopher to whom both callings owe so much; but our debt, or rather the debt of the public through us, is by far the more considerable of the two and our recognition of the master must not render us forgetful of the great disciple by whom the applications of the laryngoscope were first extended along paths which could not have been followed by the inventor.

Plastic Surgery.

As the learned Mr. Isaac Bickerstaff has observed, "the nose is a very becoming part of the face"; and its value in this respect is never fully appreciated until it is lost. Such a deprivation, however it may have been brought about, entails on the sufferer extreme misery. The absence of a nose is so utterly obvious that it must be seen by everyone and the effect on the patient may be much greater than might have been anticipated. "The patient consequently shuns society and every appearance in public and often is oppressed with a self-loathing and abasement almost amounting to the blackest despair." A nose may be lost by accident or through gangrene from cold and Maisonneuve has described a case in which the organ was congenitally absent but undoubtedly the absence of a nose is in many cases to be attributed to a less reputable cause and it is not improbable that this popular ascription of the origin of the lesion is, in part at least, the explanation of the very great mental effect of the loss of a nose. It must, however, be recognised that syphilis is not responsible for a large number of the cases; in many lupus is the cause. In some parts of the world, especially Italy and India, it has been customary to employ removal of the nose as a form of punishment, sometimes judicial, but chiefly as a mode of carrying out private revenges. Especially in some districts of India is it considered a suitable form of punishment for a husband to inflict on a wife of whose conduct he does not approve. Among the Romans this penalty was not at all rarely inflicted, both by the law and by private animosity. Inasmuch as the evil was especially prevalent in certain countries it would not be unreasonable to expect that methods of treatment should first arise there and so it proved; for countries which were pre-eminent in possessing numbers of suitable subjects for operation were the first in which operations were devised and practised for the relief of the deformity.

The earliest notice which we can discover of any attempt to repair this important lesion is to be found in Celsus. In the seventh book of his work, "De Re Medica," he mentions the practice of repairing noses by sliding flaps from the cheek and the description is sufficiently full and accurate to enable the operation to be performed. Except for a few slight references we find nothing definite after Celsus until 1442 when Manzano seems to have employed a method for restoring a lost nose. Benedictus in 1539, in his very elaborate work "Omnium a Vertice ad Calcem Morborum Ligna, Causae," the title of which shows its all-comprehensiveness, describes fully the method of restoring the nose by means of a flap taken from the arm but he does not approve of the operation. In 1548 Gilbert Cousin published a work called "Narrationum Sylva" and in this he speaks of a certain Branca de Catani who re-made noses, ears, and lips. In 1573 Andreas a Cruce *wrote a book called "Chirurgia Magna" and in it he speaks* with disapproval of the operation. Gasparo Tagliacozzi, better known by his Latinised name Taliacotius or, as it is often written, Tagliacotius, published in Venice in 1597 a large folio volume entitled "De Curtorum Chirurgia per Insitionem," and a second edition appeared at Frankfort in 1598 under a much more elaborate title. Taliacotius devotes no small amount of space to a dissertation on the importance of the nose and he quotes in support of his contention the opinions of many writers. He describes most minutely the method, always called by his name, of fashioning a new nose or other defective part from a flap of skin raised from the arm of the patient. A bridge of skin was first dissected up of the required width and length and under this was passed a piece of lint, and when granulations had fully formed the upper end of the bridge was separated and the flap of skin was inserted in the required position, the arm being retained by an apparatus in such an attitude as to prevent any traction on the new flap. After some days the attachment of the flap to the arm was divided and the arm was released. Many illustrations are given showing the mode of performing the operation and the instruments used and in addition the figures of several persons on whom the operation had been performed; if we may judge by these illustrations the results were extremely successful. The Taliacotian operation, as it was called, became very widely known and was much employed. From our knowledge of the descriptions given by one or two previous authors it is certain that an operation identical in all essentials had been devised some years previously and it seems that Branca de Catani performed the operation many times, even if he did not invent it. Nevertheless, the credit of the method is generally attributed to Taliacotius and his name is given to it.

It is not improbable that the wide extension of syphilis in Europe in the sixteenth century, with the consequent great increase in the number of the noseless, contributed to the popularity of an operation designed to efface the ravages of a discreditable disease. So striking a proceeding as the replacement of a lost nose was very naturally seized on by poets and wits and from that time onward, even to the present day, we find references to it. The lines in "Hudibras" are well known but in these we find a fallacy which had a very wide circulation. At first the skin for the new nose was always taken from the patient's own arm and this is the true Taliacotian operation, but it was soon suggested as an improvement that the reparative flap should be supplied by some other person. This method was never much employed as it was necessary to fasten together for some ten days the patient and the supplier of the skin. It was in this form that the Taliacotian operation made its appearance in popular literature. Soon certain theories arose as to the source and the fate of the transferred skin. It was said that the gluteal region furnished the most suitable skin for the purpose, on account of its toughness, but this is probably a poetical addition to the operation. Further, it was held that when the grantor (if we may employ legal phraseology) underwent any vicissitudes, however long it might be after the operation, similar changes would occur in the nose of the grantee. Should the grantor fall ill the nose would suffer too; a fever in the original possessor of the piece of skin would give rise to a localised inflammation in the transplanted organ; and if perchance the giver of the skin should die, the nose would not fail to recognise its true allegiance and would die also and we are even told that it was considered to be the correct thing to send the nose to be buried with its original owner. As SAMUEL BUTLER says in "Hudibras":

> "But when the date of nock was out,
> Off dropt the sympathetic snout."

We have no evidence to show that this idea was founded on fact. One of the most recent tales founded on the Taliacotian operation is ABOUT'S "Le Nez d'un Notaire."

The method was not received with universal approval, for GABRIEL FALLOPIUS, who wrote in 1606, said that he would prefer to remain all his life without a nose rather than to submit to such an operation, but he was thinking probably of the pain and the discomfort. In 1611 THOMAS FIENUS spoke highly of TALIACOTIUS's work and the method has been employed to some extent up to recent times. It has, however, been displaced greatly by a return to the operation described by CELSUS and by the introduction of the "Indian" method. We have mentioned above that in India there exist many opportunities for an operation for the restoration of a lost nose and therefore it is not surprising that in that country a method had been devised for this purpose. Nothing was known in Europe of any Indian method until in 1792 during the war with TIPPOO SAHIB several persons who had been taken prisoners by him were deprived of their noses. When liberated some of these had the nose restored by a Mahratta surgeon. It was then found that an operation for the restoration of a lost nose had been performed in India apparently for hundreds of years. The operation was introduced into this country by J. C. CARPUE who in 1816 published "An Account of Two Successful Operations for Restoring a Lost Nose." In this method the flap is taken from the forehead and this is the procedure usually adopted at the present time in this country.

The ultimate results of the operation are not always as brilliant as they first appear; a nose that soon after the operation is prominent and perhaps possesses a Roman curve may in a few months settle down and become comparatively inconspicuous, but, as LISTON said, "the worst made nose is infinitely superior to the horrid cavern which previously struck the passers-by with pity and disgust." The appearance of the nose is of the chief importance but with reference to the functional value of the new nose the same author described the result in a certain case: "One of my patients I have seen enjoying a pinch of snuff in which he largely indulged, apparently with as much gusto as the oldest and most experienced nose could possibly have imparted." In many cases, especially when the mutilation has followed syphilitic and tuberculous disease, very fair results can be obtained by means of an artificial nose attached to a pair of spectacles, for it is difficult in such cases to be sure that the disease will not return. We have entered somewhat fully into the history of rhinoplasty, for it was the first of the plastic operations to attain to any extensive employment, but within recent years plastic surgery has grown to large proportions and is now widely employed in many parts of the body. In THE LANCET of March 4th we published an article by Mr. C. R. B. KEETLEY in which he describes many recent advances in this department of surgery. We have now at our disposal several methods of transplanting skin. We can slide or turn a flap of skin from one part to an adjoining part of the body, as in the Celsus method of rhinoplasty or in the Indian operation, or we can, as in the Taliacotian operation bring it from a limb. We can, moreover, now, with suitable precautions, transfer bodily a piece of skin, including its whole thickness, from one part to another with due aseptic precautions and in this method another person may conveniently supply the material. Skin grafting, too, has increased in usefulness and in addition to the older method of REVERDIN, devised in 1869, we have that introduced by THIERSCH. Thus the surgeon is provided with many means of covering raw surfaces which were unknown to his predecessors, so that he is enabled to carry out many procedures hitherto impossible. In plastic surgery in its widest sense lie some of the greatest future advances of our art and it is not possible at the present day to do more than to speculate as to what may be in store for us in this direction.

◆

Plague in India.

THE serious news which our Indian correspondent sends regarding the mortality from plague in that country indicates that no progress has been made in the control of the disease. On the contrary, the situation in India is becoming worse year by year and not only threatens to be, but is already, one of the greatest catastrophes of modern times. In January of this year over 100,000 deaths were recorded from plague in India. In February there were another 100,000, and 34,000 and 35,000 deaths are the numbers which have been reported during the past two weeks. Thus a greater disaster has occurred to our Indian population since the commencement of 1905 than has happened to the Russian army in Manchuria. Have those responsible for the welfare of our Indian empire fully realised the gravity of the situation either from its humane or political aspects? As regards the humane side, it is obvious that active measures proportionate to the greatness of the issues at stake require to be taken. Are these being organised and carried out? We doubt if the reply that can be given is satisfactory. It is true that an inquiry is to be undertaken by the Lister Institute of

Coombe, 9, Lord-street West, Southport," still appears in the official list? We happen to be aware that he who was George Augustus Coombe very many years ago changed his name and is now Sir George Pilkington. Want of attention to such a matter as this opens wide the gate for personation. Turning to the Dental Register we find an increase of 58 names over the number on the Register for 1904. The number of persons registered solely on the ground of having been in practice at the time of the passing of the Dentists Act now amounts to 48·90 per cent. of the whole, while the number of licentiates in dental surgery of one of the authorities of the United Kingdom for the first time exceeds that of all others—viz., 50·15 per cent. The small percentage (0·95) remaining represents the American and colonial practitioners and practitioners who, in addition to being registered as in practice, are possessed of some registered medical or surgical qualification. It may be added that the number of licentiates in dental surgery who are possessed of medical or surgical qualifications, or both, continues to grow, the 2374 licentiates possessing between them 282 registered medical or surgical qualifications and three higher dental qualifications.

CURRENT THEORIES OF THE HEREDITARY PROCESS.

THE eighth and last of a series of lectures[1] on the above subject was delivered by Professor W. F. R. Weldon, F.R.S., at University College, London, on Feb. 14th, a further extensive series of experiments by Czermak on peas and beans being made the basis of a test of the Mendelian theories of segregation and gametic purity. Czermak crossed two races of peas characterised by cotyledons the growth of which was of the epigeal and hypogeal type respectively. The hybrid progeny of the crossing was found to consist of 30 plants which showed the epigeal habit as regards their cotyledons, 32 which developed the hypogeal habit, and 18 which were of an intermediate type, "a very imperfect segregation," said Professor Weldon. In the third generation none of these three types of hybrids bred true, each produced when fertilised by its own kind a mixed progeny of members of all the three kinds. Czermak made a further series of experiments on a white-flowered pea (*pisum sativum*) which he crossed with a red or purple species (*pisum arvense*). The hybrid progeny which resulted were all typically red, like *pisum arvense*. They were examples of the dominance of the red colour and as this colour had long been known to prevail in many stable and "good" species of peas such a dominance was to be regarded as an instance of atavism. These hybrids, however, were not "pure," for on inter-breeding from them different coloured individuals were obtained. Thus, of a total of 397 plants produced by inter-breeding: 239 were of the red type, 75 were rose-coloured, and 83 were white, a proportion of nine red, three rose-coloured, and four white, which could not be reconciled with the Mendelian formula. Czermak suggests that, if, however, white and rose were postulated as the atavistic or ancestral colours of the two races of peas, the facts would more closely conform to Mendel's formula. A further series of these experiments was carried out by Czermak on the three types of plants (239 red, 75 rose-coloured, and 83 white), each type of plant being fertilised with others of its type. Of the red plants thus treated some produced red and others white and rose-coloured offspring. Of the white plants the offspring were mostly white, while the rose-coloured plants in the majority of cases gave only a rose and white progeny. The results obtained in the last three series of experiments were such as not to be explained on any Mendelian formula. Czermak also experimented with ordinary kidney beans of different colours, bronze and white. The crossing of these varieties produced a hybrid progeny of beans with coats of dark brown colour mottled with black spots (488 seeds) and "tortoise-shell" markings and 161 white seeds. The mottled seeds when sown gave rise to both "coloured" and white-seeded beans. Of the coloured seeds 52 per cent. were of the mottled "tortoise-shell" appearance and 48 per cent. were of a uniform bronze colour, a distribution of colour which could not be reduced to any Mendelian formula. The white seed bred true. The experiments were carried out for four generations and amidst varying results one conspicuous character asserted itself in the fourth generation—viz., all mottled beans obtained in the fourth generation bred true, the process of mottling having become dominant in several strains. These were illustrations of the kind of researches which made it difficult to accept the general formula of segregation of Mendel or the hypothesis of gametic purity. A formula of inheritance propounded and developed by Francis Galton gave better results. The Galtonian theory postulated the presence of "elements" in the germ cells of one generation, which were of two kinds—viz., active or dominant elements and groups of elements, which determined the heritable characters of the progeny or second generation, and latent or recessive elements which passed through the bodies of one or more generations without appearing to affect them. By investigation of records of human family histories conducted on a large scale by Galton and his fellow workers a law of heredity has been formulated (Galton's law) which the extensive biometrical investigations of Karl Pearson have shown to be very approximately expressed by a mathematical formula. This "law of ancestral heredity" is that the two parents contribute between themselves one-half of the total heritage of the offspring, that the four grandparents contribute one-quarter, the eight great-grandparents one-eighth, and so on. Thus the sum of the ancestral contributions is expressed by the series ($\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16}$ ......), which, being equal to 1, expresses the whole heritage. If the chromosomes of the conjugating germ cells divided always transversely into equal segments such divisions would be always quantitative and the Mendelian hypothesis of gametic purity would be always realised. But if the cleavage of chromosomes were horizontal qualitative differences would appear in the divided parts of the chromosomes and "mixture" of characters would invariably appear when different races or varieties were crossed. The most recent and careful researches seem to favour the view that both processes (quantitative and qualitative division of chromosomes) occur and that by varying segregations and varying dominances "blending" of characters and "mosaic" hybrids of all kinds are possible among plants and animals.

TEACHING THE TRAWLERS.

ALL that affects the food of the people interests the medical profession. We have pleasure in calling attention to a promising development of the work of the Lancashire county council in conjunction with the sea-board counties from Cumberland to Cardigan, the duty of which it is to maintain the Lancashire and Western Sea Fisheries Board and to see that the by-laws are duly observed. At Piel Island, near Barrow, a fishery school has been established in what was formerly a "marine residence." The life-history of the plaice, the sole, and other fish is taught to classes of selected fishermen in the spawning months of March to May. During this time "breeze-tanned, brawny fishermen" may be seen bending over microscopes learning the life-history of the creatures that will some day make up a day's catch. The course lasts a fortnight and then "they go back understanding why steam trawling should not be allowed within the three-mile limit, especially with shrimp nets, and why the six-inch net, which will catch a half pound sole, is quite small enough." Recently members of the joint committee saw at the hatchery some 15 fishermen hearing and also understanding the teaching given by members of the staff. The following anecdote shows the practical bearing of the teaching: "A persistent trawler on prohibited ground was prosecuted time after time without avail. At last he was given a practical demonstration of the harm he was doing and finally taken to the 'school' for a fortnight's teaching and convinced of the error of his ways." After their schooling the men go back and enlighten their comrades. This educative work, initiated by Professor W. A. Herdman, F.R.S., and personally directed by Mr. Andrew Scott and Mr. James Johnstone at the Fisheries' School, promises to be of great value in checking the almost incredible waste of immature fish that has hitherto been the rule.

[1] Abstracts of the first, second, third lectures were published in THE LAN (p. 181), Feb. 4th (p. 307) and 25th (p. (p. 657), and 18th (p. 732), 1905, respectively.

HYGIENE AND THE METROPOLITAN POLICE COURTS.

IN our issue of Feb. 11th, p. 378 (that is to say six weeks ago), we had occasion to remark in an annotation under the above heading that "the interior of a metropolitan police court, sanitarily speaking, is very seldom prepossessing, the walls and benches are grimy, and the accommodation rarely affords the calculated 'health space.' The experience of those who occasionally attend a metropolitan police court is invariably disagreeable. There is usually present a very large representation of the 'great unwashed' and it is with these that the medical man, the man of law, the expert witness, and other respectably inclined persons are compelled to 'hob-nob.' ...... Ventilation is nearly always a negligible quantity, as is evident from the fœtor which commonly pervades a court." We were not aware when writing these lines that at least one unhealthy, insanitary, and incommodious metropolitan police court was just about to be abandoned in favour of a new building designed in accordance with hygienic requirement and altogether in the direction of reform indicated in our article. A fortnight ago we received an announcement from Scotland Yard to the effect "that the new Tower Bridge police court, which is to take the place of the existing Southwark police court, will be opened for business on the 25th instant," and we were invited to send a representative to see the court before the opening day, "having regard to the terms of the article" and to our remarks on the subject from the sanitary point of view. We may say at once that the new Tower Bridge police court is a decided step in the direction of reform and not the least important feature of it is that two justice-rooms are provided, so that the present objectionable method (of which we complained) of bringing non-criminals into close contact with criminals, it is hoped, will be abolished. To keep cleanly disposed persons waiting in the court while a number of petty or criminal offences are being tried or about to be tried is intolerable and opposed to all sense of decency and respect. It is absurd that a case, say, under the Sale of Food and Drugs Act, involving the elucidation of technical points and the attendance of professional witnesses, should be placed side by side with a case of criminal offence, an occurrence which leads to the inevitable mixing of the witnesses engaged in both cases. We are glad to learn that the new police courts at Shoreditch and at Clerkenwell are being constructed on similar lines. On the whole, the sanitary arrangements at the new Tower Bridge police court are satisfactory, the courts are light and airy, and the arrangements for ventilation and warming are excellent. For the latter the low-pressure system of hot water is adopted and at each radiator there are air inlets, the warmer air inducing a flow of fresh air from the outside. The ventilation and the lighting of the court can be easily controlled from the magistrate's chair, to the left of which are a number of switches operating electric fans and electric lights. The accommodation for witnesses is good but it is somewhat limited for the general public. The benches and the furniture are of fumed oak. The public waiting hall at the entrance is admirably designed, lofty, and roomy. The cells, 30 in all, are well lighted and provided with warming apparatus and in most instances water-closets, the working of both being controlled from the outside. The floors of the cells are of asphalt and the walls have a high dado of glazed tile. The architect of the new court is Mr. J. Dixon Butler, the police surveyor, and the work, costing altogether £45,000, has been carried out by Messrs. Mowlem and Co. If our future police courts are constructed on this commendable plan witnesses and others will no longer resent being called upon to attend on the score that the environment is unhealthy and filthy, as has too long been the case.

PNEUMOCOCCIC ARTHRITIS IN A NEWLY BORN CHILD.

PNEUMOCOCCIC arthritis has been recognised only in recent years. In 1901 Dr. E. J. Cave recorded the first case in this country and exhaustively reviewed the subject.[1] He described pneumococcic arthritis as essentially a disease of adult life; out of 31 cases he found that only two occurred in children, at the ages of five and eight years respectively. In the *Archives Générales de Médecine* of Feb. 28th M. Nattan-Larrier has reported from the clinic of Professor Dieulafoy at the Hôtel-Dieu, Paris, a case, apparently the only one on record, in which pneumococcic arthritis was observed in the newly born. A male infant was born after a difficult but otherwise normal first labour on Sept. 5th, 1904. He was the subject of hare-lip and cleft palate. On the 8th a plastic operation was performed on the lip. He progressed favourably until the 12th, when there was a little sero-purulent discharge from the orifices of the sutures. When the latter were removed on the 15th union was found to be very incomplete and the wound was covered with pus. On the 20th the edges of the wound were greyish-red and covered with pus. The general condition was bad, there were vomiting and fœtid stools, and he had lost weight. On the 24th his mother noticed that he cried when placed on the right side or when the right arm was touched and that the right shoulder was red and swollen. On the 25th the swelling was greater and the arm was immobile. On the 26th he was taken to the hospital. He was wasted and pale and the fontanelles were depressed. There was considerable swelling of the right shoulder-joint which was of the size of a mandarin orange; the overlying skin was red and œdematous and showed dilated veins. Deep fluctuation was felt at the anterior border of the deltoid. Purulent arthritis was diagnosed. Disseminated râles were heard all over the chest. The spleen was palpable. The temperature was 100° F. in the morning and 101·5° in the evening. On the 27th the general condition was worse, the skin was dry, the eyes were sunken, the temperature was 104·2°, and death took place. At the necropsy thick viscid greenish pus—typical pneumococcic pus—was found in the right shoulder-joint. The synovial membrane was thickened and reddish and covered in places by an adherent fibrino-purulent layer. The articular cartilage was roughened and eroded. The lungs were everywhere congested and œdematous but especially at the bases. There were no signs of pneumonia or broncho-pneumonia. Microscopical examination of the pus showed disintegrated leucocytes and a large number of diplococci which on staining and on culture were proved to be pneumococci. Pneumococcic arthritis usually is secondary to pneumonic or bronchopneumonic infection (in 28 cases out of 32). In this case neither was present and the source of infection evidently was the wound in the mouth, for the pneumococcus was found in the pus. It will be remembered that the organism often occurs as a saprophyte in the mouth and therefore infection of a wound might easily take place.

---

[1] THE LANCET, Jan. 12th, 1901, p. 82.

THE UMBERTO I. PRIZE.

A PRIZE is awarded quinquennially in Italy in memory of H.M. King Umberto I. The subject of competition is orthopædic surgery and the adjudication is made by an international committee of three members. This year the adjudicators are Professor Bassini of Padua, Professor Mikulicz of Breslau, and Mr. Bernard Roth, F.R.C.S. Eng. There are 14 competitors for the prize, of whom nine are German, two are English, two French, and one American.

FRENCH CONGRESS OF CLIMATOLOGY AND HYGIENE OF TOWNS.

THE French Congress of Climatology and Hygiene of Towns, which was founded by Dr. Huchard in 1904, will hold its second meeting in the end of April, commencing at Arcachon on April 24th, spending the next four days there, and proceeding to Pau on the evening of the 28th. Professor Renaut of Lyons will preside. The subjects to be considered in the Section of Climatology will be the climatology, sanatoriums, and seaside hospitals of the French Atlantic coast, the treatment of tuberculosis, and the climate of Pau. During the meeting at Arcachon excursion parties will visit the forest and places on the coast. At Pau fêtes will be organised by the municipality; there will be an excursion to Biarritz on April 30th and one to Hendaye Sanatorium and Fontarabia on May 1st. Medical men, sanitary engineers, and chemists are eligible as titular members of the congress and pay a subscription of 20 francs; medical students and wives and children of titular members are eligible as associate members for whom the subscription is ten francs. A reduction of 50 per cent. is granted by all the French railways to both classes of members. Titles of communications should be sent not later than April 1st to the general secretary, Dr. A. Festal, Villa David, Arcachon. Applications for membership, together with the amount of the subscription, should be sent not later than April 5th to the general treasurer, Dr. Déchamp, Villa Tibur, Arcachon.

PREGNANCY IN A CASE OF ANTE-LATERAL FLEXION OF THE UTERUS MISTAKEN FOR EXTRA-UTERINE PREGNANCY.

IN the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* M. Fieux and M. Chavannaz have reported the following case. A married woman became pregnant for the first time at the age of 21 years. Labour was terminated by the application of the forceps for uterine inertia. At the age of 25 years she again became pregnant and labour was completed normally. After this confinement she suffered from gastro-intestinal troubles characterised by marked dilatation of the stomach and frequent attacks of hepatic colic. At the beginning of 1903 she had missed three periods and the breasts had enlarged. She consulted an accoucheur to confirm her belief that she was pregnant. He diagnosed salpingitis and passed a sound. Six days later a fœtus measuring three and a half inches was expelled. After this menstruation was regular until March, 1904, when it was expected on the 25th. Not until April 8th was there a slight discharge which on the 10th increased considerably. The hæmorrhage was accompanied by severe pains and the expulsion of what her husband, who was a medical man, regarded as a piece of membrane. The os was soft and patulous. The hæmorrhage and the expulsion of membrane continued until April 18th when it ceased and the patient resumed her ordinary life. On May 26th hæmorrhage recurred and the discharge was dark red. On the 27th there was acute pain in the lower abdomen on the left side with syncope for ten minutes. The discharge continued until June 1st. After this the general health became bad; the face was drawn, vomiting frequently occurred, and the pulse was small. The lower abdomen was constantly painful, sometimes on the left and at other times on the right side. A tumour of the size of a Tangerine orange was felt in the hypogastrium on the left of the median line. On the 6th this tumour became the seat of painful crises. Measurement of the uterine cavity showed that it was eight centimetres deep and this operation was not followed by any ill result. On the 12th M. Fieux saw the patient in consultation. *The diagnosis of extra-uterine pregnancy seemed to be clear.* To the left of the middle line was a tumour of the size of a small orange, rounded, painful, and scarcely moveable. It was hard and never appeared to have shown change of consistency. The os was softened and pushed backwards and a little to the right. The anterior and left fornices were obliterated by the tumour which bulged into the pelvis. A deep groove separated the tumour from the part of the uterus accessible to the finger in the vagina. It seemed that the uterus could be slightly oscillated by the finger in the vagina, while with the hand on the abdomen the tumour was felt almost completely fixed. On the 25th the abdomen was opened and the tumour was found to be the body of the uterus flexed forwards and to the left. It was placed in a good position without difficulty for there were no adhesions. A three months' gravid uterus was then evident. The right ovary contained a cyst of the size of a pigeon's egg and was removed. Good recovery followed, though on the fourth and fifth days after operation there were pains resembling those of labour. At the time of the report the pregnancy was in the ninth month and was pursuing its normal course. M. Fieux and M. Chavannaz point out the great resemblance of the case to one of extra-uterine pregnancy both in the history and the physical signs but they call attention to one point in which the bimanual examination was not satisfactory. The independence between the supposed tumour and the body of the uterus was not evident to the hand placed on the abdomen. They recall the advice of Varnier: "It is above rather than below that the independence between the body of the uterus and a pelvic tumour should be felt in order to affirm that it is juxta-uterine."

THE ANNIVERSARY DINNER OF THE MEDICAL SOCIETY OF LONDON.

THE 132nd anniversary dinner of the Medical Society of London, which was held on March 15th at the Whitehall Rooms, was attended by a large and representative gathering of Fellows and by several distinguished guests. Some excellent speeches were delivered, the most prominent note in which was that of confederation. Sir William S. Church emphasised the advantages which would accrue from an amalgamation of the medical societies of the metropolis and expressed a hope that any difficulties standing in the way would be successfully overcome. He believed that this would be possible to arrange without necessarily destroying the individuality and special characters of the various component bodies. Sir Arthur W. Rucker, in responding for the guests, spoke in similarly strong terms of the project for centralising the teaching of the preliminary scientific subjects which has been energetically taken up by the

University of London with a view to giving the medical student in London advantages equal to those enjoyed by the students in large provincial universities. Judging from the applause with which the exposition of both schemes was greeted it would seem that each had the hearty approval of the audience.

THE HEALTH OF THE KING.

ON Saturday, the 11th inst., His Majesty received a chill, probably when driving in his motor car. Some bronchial catarrh with a slight rise of temperature and increase in the pulse-rate ensued so that it was found necessary by his medical attendants to advise him to remain indoors in an equable temperature. We are glad to say that His Majesty has progressed satisfactorily and on Wednesday was able to go out.

ANTE-NATAL INJURIES.

A VERY interesting question was raised in a case before the Exeter magistrates when a woman, in applying for a separation order said that her last child had been born with black eyes and a discoloured face as the result of her husband's violence. The medico-legal question involved is one of much interest. What is the usual effect on the fœtus in utero of traumatism applied to the abdomen of the mother? The amount of injury which a pregnant woman may sustain and yet give birth at full term to a healthy child is astonishing. One of the most remarkable cases is that recorded by Corey. The patient, a woman three months pregnant, was tossed by a cow. There was an abdominal wound through which protruded the great omentum, the descending and transverse colon, most of the small intestine, and the pyloric end of the stomach. Three and a half hours after the accident the viscera were replaced under an anæsthetic and the edges of the wound were pared and sutured. The woman made a perfect recovery and gave birth at full term to a healthy and uninjured child. Tiffany, who has collected a number of such cases, quotes one of a woman who at the eighth month of pregnancy was almost buried by the fall of a clay wall and received a number of wounds on the head, 32 stitches having to be inserted. In spite of this the pregnancy continued to full term and the patient gave birth to a healthy female child. The escape of the fœtus from injury in such cases is no doubt to be explained by its protected position in the mother's abdomen and by the presence of the liquor amnii. Unhappily in many instances of severe abdominal injuries the outcome is not so fortunate and that such injuries may result in serious damage to the child is only too certain. Neugebauer, for instance, relates the case of a woman who, when near full term, committed suicide by jumping from a second-floor window. She ruptured her uterus and a dead fœtus with a fracture of the parietal bone was found lying free in the abdominal cavity. A great many of the recorded cases, however, especially in the older literature, in which various injuries, for example, fractures and dislocations of the fœtal bones, are described, must be received with scepticism, as such conditions are more often due to defects of development than to direct injury to the fœtus in utero. An instance of this kind is no doubt the case recorded of a woman who at the seventh month of pregnancy fell and struck her abdomen against a tub. She was delivered at full term of a child who had a deep cleft in the cheek involving the anterior part of the helix and antihelix of the left pinna and extending forwards as far as the nose. The external auditory meatus was also obliterated. This was in all probability not a case of injury at all but an example of an intermaxillary fissure of the face. Such a fissure usually starts at the angle of the mouth and pursues an outward and upward course towards the ear. It is most commonly met with on the left side, as in this case, and is often associated with various deformities of the external ear. It is usually asserted that intra-uterine fractures are due to external violence but this is far from always the case. Numerous examples of fractures involving the long bones and the cranial bones can be collected, especially from the older literature. Gurlt has recorded a large number of such cases and his paper proves that they are by no means uncommon. Their explanation, however, is not so simple. In many instances they are met with in association with other deformities or complete or partial absence of some of the other bones. The view put forward by Ballantyne with regard to these conditions is probably the correct one—namely, that the great majority are really due not to external violence but to the result of amniotic adhesions. Further support is given to this view by the fact that not infrequently a cicatrix has been found over the site of the fracture and this is explained by the supposition that a band of the amnion was attached at this point and produced by its traction distortion of the soft cartilage of the developing bone and as a result the appearance of a healed fracture. In the same way it is probable that most of the recorded cases of intra-uterine dislocations are also not the result of direct trauma but are due to anomalies of growth from the pressure exercised by an ill-developed and unseparated amnion. The curious cases of so-called recent wounds of the skin which are met with from time to time in newly born babies, and which have always been the cause of a great deal of curious speculation, must be explained in the same way and are in reality due to the rupture of an amniotic adhesion during parturition. The tearing through of such an adhesion close to the skin would give rise to a raw area. The Exeter magistrates apparently believed the story of the woman who applied for their assistance and it is possible that they took a correct view of the case. That severe injuries inflicted upon the mother may affect the fœtus in utero is certain and it would be rash to assert that in certain circumstances, as, for example, a deficiency of the liquor amnii, even comparatively slight violence could not cause damage to the unborn child. At the same time in considering such cases the medical man must always remember that a very large number of so-called injuries are in reality faults of development and are due to trauma it is true, but to trauma produced by the pressure of an undeveloped amnion and not to trauma the result of external violence.

A PRIZE of £100 and a silver cup have been offered by Mr. Edgar Speyer, a member of the General Council of King Edward's Hospital Fund for London, and a generous supporter of the Fund, for the best essay on "The Economical Management of an Efficient Voluntary Hospital." The Prince of Wales as President of the Fund has approved Mr. Speyer's action and has consented to present the prize to the successful essayist. The competition is only open to the paid secretaries and assistant secretaries of voluntary hospitals in the United Kingdom of Great Britain and Ireland. Further particulars and conditions will be supplied on application by the honorary secretaries of the Fund, 81, Cheapside, London, E.C.

THE fourth Congress of the German Society of Orthopædic Surgery will meet at Langenbeck House in Ziegelstrasse, Berlin, on April 25th, the day before the meeting of the German Surgical Society.

THE King has been pleased to appoint Dr. Noel Dean Bardswell, at present director of the Mundesley Sanatorium, to be medical superintendent of the King Edward VII. Sanatorium. It is understood that Dr. Bardswell will visit foreign sanatoriums for some little time before commencing his work at the King's Sanatorium, which, it is hoped, will be opened in the early part of 1906.

IN reference to our leading article upon the case of Miller *v.* Miller and Fowler we should have pointed out that Dr. Fowler's case was conducted throughout to its triumphant issue by the London and Counties Medical Protection Society, Limited, whose assistance was sought by Dr. Fowler at the beginning of the case.

Lord Strathcona will take the chair at the festival dinner of the National Hospital for the Paralysed and Epileptic on Thursday, April 13th, in the Whitehall Rooms of the Hôtel Métropole, at 7 P.M. Communications should be addressed to Mr. Godfrey Hamilton at the hospital.

THE annual meeting of the Coal Smoke Abatement Society will be held, by permission of Mr. Frederick Harrison and Mr. Cyril Maude, at the Haymarket Theatre, London, on Thursday, March 30th, at 3.30 P.M. His Grace the Duke of Fife, K.T., will preside.

THE death occurred last week of Miss Jane Catherine Shaw-Stewart who assisted Miss Florence Nightingale as a nurse during the Crimean war and was afterwards matron-superintendent of Netley Hospital, which position she held till 1868.

THE GARCIA CENTENARY.

Señor Manuel Garcia, the eminent teacher of singing, through whose labours laryngoscopy has become one of the most important handmaids to the medical profession in its battle with the dread diseases of the throat, celebrated the hundredth anniversary of his birthday on March 17th, when representatives of music and science from all parts of the world assembled at the rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, London, W., to do him honour. Among those present were Madame Garcia and Miss Garcia.

As Señor Garcia entered the room at noon wearing the insignia of the honorary Commandership of the Royal Victorian Order conferred upon him by the King, a volley of cheers greeted him from the assembled company. This hearty reception he acknowledged by bowing and immediately afterwards seated himself in the chair upon the dais which had been specially placed there for him as a seat of honour.

Sir **FELIX SEMON**, chairman of the Garcia committee, then announced that His Majesty the King had just received Señor Garcia at Buckingham Palace in order to express to him his congratulations and his recognition of all that Señor Garcia had done for medicine and music. At the same time the King had conferred upon him the honorary Commandership of the Royal Victorian Order. His Majesty, at the conclusion of the interview, expressed a wish to be personally represented at the banquet, and said that he would desire his Lord-in-Waiting, Lord Suffield, to attend as his representative.

The Marquis **DE VILLALOBAR** (the Spanish Chargé d'Affaires) then delivered a congratulatory message from the King of Spain and invested Señor Garcia with the Order of King Don Alphonse XII.

Professor **FRÄNKEL** said that the genius of Señor Garcia had thrown light on the dark places of the larynx and the source of the living human voice. In recognition of his merits the German Emperor had conferred upon him the great gold medal for science. This rarely awarded distinction he now had the pleasure of presenting to Señor Garcia at the request of the Minister for Public Instruction.

An address from the Royal Society was then presented by Sir **ARCHIBALD GEIKIE** (principal secretary), Professor **FRANCIS DARWIN** (foreign secretary), and Dr. **HALLIBURTON**, F.R.S. The address was as follows:—

> The Royal Society of London join very cordially in congratulating Manuel Garcia on the celebration of his 100th birthday. The President and Council recall with much pleasure [illegible] Society afforded in their proceedings [illegible] for publishing to the scientific world [illegible] paper in which Señor Garcia laid the foundation of the experimental study of voice production and, at the same time through the laryngoscope, provided the starting point for a new department of [illegible] The Royal Society trust that Señor Garcia [illegible] to come to enjoy in good health the esteem [illegible] ment and his high personal character hav[illegible] and sealed on behalf of the Royal Socie[illegible] Knowledge) WILLIAM HUGGINS, President.

Sir **ARCHIBALD GEIKIE** (corresponding member of the Prussian Academy of Sciences) read the following telegram:—

> To the first investigator of the human voice *by a new method* which for all time has bestowed a signal service on art, on science, and on *suffering humanity*, the Royal Prussian Academy of Sciences sends on his 100th birthday its most respectful congratulations.—WALDEYER, Secretary.

An address was next read from the University of Königsberg which had conferred on Señor Garcia the honorary degree of Doctor nearly half a century ago.

An address was then presented from the Victoria University of Manchester by Professor **STIRLING**, F.R.S., Dr. W. **MILLIGAN**, and Dr. S. **MORITZ**, one from the Medical Faculty of Heidelberg, and another from Señor Garcia's old pupils, among whom were Mr. Santley, Madame Blanche Marchesi, and Herr and Fräulein Stockhausen.

Mr. **OTTO GOLDSCHMIDT**, the husband of Jenny Lind, said that his late wife to the end of her days venerated Señor Garcia who helped her to take the position in the musical world which she attained.

An address from the Royal Academy of Music was presented by Mr. Thomas Threlfall (chairman), Sir Alexander Mackenzie (principal), Mr. Walter Macfarren, Mr. Edward E. Cooper (honorary treasurer), Cavaliere Randegger, Mr. John Thomas, Mr. F. Walker, and Mr. F. W. Renaut (secretary), and an address from the Royal College of Music, was presented by Sir Hubert Parry (principal), Sir Walter Parratt, Mr. Henry Blower, Sir C. Villiers Stanford, Dr. C. Harford Lloyd, Mr. Eaton Faning, Mus.Doc., the Hon. Spencer Lyttelton, C.B., and Mr. Frank Pownall.

A large number of messages of congratulation were also sent by British and foreign laryngological societies and associations.

Dr. **BOTELLA** (Madrid), the official delegate of the Spanish Government and of the Spanish Laryngological Society, said that the laryngoscope had put within the range of science many diseases the existence of which could never have been suspected, had made possible their treatment, and had saved from suffering and death many lives. The Spanish Government sent its enthusiastic congratulations and the Spanish Laryngological Society begged Señor Garcia's acceptance of the office of "President of Honour."

The address from the Laryngological Society of London, of which Señor Garcia is the oldest honorary member, referred to him as "dear and revered master" and expressed the wish that "we may often have the pleasure and privilege of seeing the venerable father of laryngoscopy amongst us."

It was announced that several foreign societies had conferred their honorary membership upon Señor Garcia.

The proceedings were brought to a close by the presentation to Señor Garcia of his portrait painted by Mr. Sargent, R.A.

In returning thanks Señor **GARCIA** (addressing the Spanish Chargé d'Affaires) said: Sir, will you tell my King for me how deeply grateful I am to him for thus remembering that in this country, which has sheltered me so long, he has a loyal and a loving subject? Will you express my overwhelming sense of this great honour and convey to him my reverent—if a subject may be so bold—my loving thanks? You, Sir (addressing Professor Fränkel), will undertake of your great courtesy to make known to His Majesty the German Emperor my deep sense of the honour he has conferred on a stranger and you will ask him to accept my grateful thanks. You, Sir (addressing Sir Archibald Geikie), who represent the illustrious English society that first gave me a hearing (the Royal Society); you, Professor Stirling, by whom the learning of England's second capital (the University of Manchester), sends me greeting (at this point Señor Garcia handed the MS. of his reply to Sir Felix Semon, requesting him to finish reading it)—you who have come from distant Königsberg to recall the grateful memory of those who gave the unknown man a place among them, you who represent the world renowned Academy of Sciences of Berlin among the members of which are some I count dear friends, and you dear Sir who bring me the greeting of a city of youth whose very name seems to set joy bells ringing, you Sir, from Heidelberg how shall I thank you all if your good will should fail to interpret my poor faltering words? You doctors laryngologists dear friends to whom the little instrument to which such kind allusion has been made owes all its power for good you representatives of the great music schools of London in one of which I passed so many years working happily beside brother musicians and to the other of which I have so often come to mark with pride our own great art of music, you too my pupils among whom it rejoices me so keenly to welcome faces missed for many years and found again to-day while others have been with me near and dear to you all thanks from an old heart that he did not know what youth it still possessed till it expanded to embrace you all This portrait from the hand of this great master which grew in happy hours too few for me since they passed so rapidly in his companionship shall be my pride and joy in the days to come (Here Senor Garcia resumed his speech) If you will bear with me a moment longer I should like to say one little inadequate word of thanks to him from whose initiative this wonderful demonstration has sprung my friend Sir Felix Semon *with whose name I link that of an institution dear to me* beyond all others the Laryngological Society of London and its chosen representative that social Atlas the Garcia Committee

In the afternoon there was a special sitting of the Laryngological Society of London at which the numerous distinguished representatives of the learned societies were present A large number of pathological specimens drawn from the medical museums specially selected and arranged by Dr J H *Pegler, the* curator to the society were exhibited Among the naked eye exhibits were the following —Mr R Lake Pachydermia of the Larynx in a man aged 24 years The glottis was much *stenosed and completely* closed in one situation (Royal College of Surgeons Museum) Dr E Clifford Beale Lymphoma of the Larynx involving the epiglottis the ventricular band and the arytenoid cartilage of the left side (reported in THE LANCET of Oct 15th, 1887) (Great Northern Central Hospital) Mr Charters J Symonds Carcinoma of the Larynx complete extirpation (Guy s Hospital Museum) Sir Felix Semon Carcinoma of the Larynx partial [illegible] cell carcinoma of the ventricle [illegible] e late Mr Montague Williams) [illegible] um) Mr H T Butlin Carci [illegible] l excision of the true and false vocal cords for carcinoma of the under surface of the vocal cord in a *man* aged 50 years (St Bartholomew s Hospital Museum) Mr P R W de Santi Papilloma of the Septum Nasi removed from a man aged 89 years no recurrence (Westminster Hospital Museum) Mr Butlin Œsophageal *Diverticulum* removed by operation from a man aged 50 years (St Bartholomew s Hospital Museum) Mr Arthur H Cheatle contributed a microscopical section of Polypoid Growth of Lymphoid Character springing from the Right Supratonsillar Fossa (published in the Proceedings of the Larynological *Society* vol xi with coloured drawing)

In the evening at the Hotel Cecil Senor Garcia was entertained at dinner There was present a large and distinguished company of ladies and gentlemen.

After the loyal toasts had been duly honoured the Chairman (Mr CHARTERS J SYMONDS) called upon the Marquis DE VILLALOBAR *to read* a message from the King of Spain who had conferred upon their distinguished guest the *Grand Cross* of the Order of *Alphonse* XII The message was as follows —

Iv Sero

Dustbins on the Kerbstone

A RECENT prosecution at the South Western police court is of considerable interest to many householders and to local sanitary authorities The complainant was Mr J W Baines a barrister and assistant legal adviser to the Local [illegible]

[illegible] asking for the removal of refuse from his residence The difficulty arose out of a by law prepared by the *London* County Council and approved by the Local Government Board requiring occupiers within a prescribed area under a *penalty to facilitate the removal of house refuse by placing* it in receptacles on the public footway Householders in the district in which Mr Baines lives received at the close of last year notices from the borough council that on and after Jan 1st 1905 the refuse of houses in specified roads would be removed under this by law between 7 and 9 A M In Mr Baines s case and no doubt in the cases of many of his neighbours in Putney this necessitates the carrying of the whole of the refuse from a villa of a substantial size down a carriage drive as well as across the footway to the kerbstone at some time *presumably not much later than* 7 A M Mr Baines declined to order his servants to do this and instead invited the council to remove the refuse for itself under Section 30 of the Public Health (London) Act 1891 The borough council in its turn declined basing its refusal on the County Council by law referred to above, and Mr Baines issued a summons against it After considerable argument from counsel Mr Francis gave his decision in favour of Mr Baines and imposed a fine of £1 upon the council with 25 guineas costs offering at the same *time to state a case for an appeal to the Divisional* Court He did not hold that the County Council by law was bad but that it was not intended or suited for universal application It was in his opinion made to cover certain cases and the way in which the council had tried to enforce it was wrong in that it had refused to remove the household refuse from the premises in question *He also regarded the placing of dustbins on the* kerbstone as an obstruction of the highway Considerable sympathy with Mr Baines is no doubt felt by many persons whose residences are similarly situated to his and not unreasonably The object of the council is no doubt to effect an economy of trouble *time and money* in the removal of dust and other refuse from houses The bin placed upon the *kerbstone* unquestionably *does this* particularly in streets of continuous houses some of which perhaps contain many tenements and to a certain extent the system has the advantage of preventing accumulations of offensive matter indoors On the other hand the dustbin on the kerbstone and the present *plan of emptying it* by hand are by no means ideal from a sanitary point of view as any observer on a windy day can *satisfy himself* From Mr Baines s *point* of view it is easy to see that to have the refuse of a large house carried down a drive by the house*holder s domestic* servants is difficult and almost impossible in many circumstances It is not at any time women s work and in wet weather or in snow they would be still more unfitted to perform it Even in large houses where men servants are kept the butler and the footman would hardly relish being turned into dustmen. The work, in fact, is such that men specially employed to perform it are practically necessary, whether a local council employs them or the householder. The appeal upon the case which apparently Mr. Francis is to state will be watched with much interest, as the possibility of enforcing the County Council by-law universally within the County of London is no doubt one of the issues involved.

The Prevention of Live Burial.

The London Association for the Prevention of Premature Burial has prepared a Bill which presumably will be introduced in the House of Commons by a private member and doubtless will share the fate of many similar documents. It contains proposals which, if for no other reason than on account of the expense involved, will fail to commend themselves to ratepayers. It empowers local authorities to provide "waiting mortuaries," warmed, lighted, and ventilated, for the reception of bodies should the surroundings in the home of the deceased not be suitable for the purpose. In these waiting mortuaries the bodies are to lie until the requirements of the proposed Act are complied with and they may be furnished with a hall for bodies of no particular classification, with an apartment for infectious cases, another for cases that may require judicial action, a post-mortem room with laboratory and apparatus for resuscitation, and quarters for a resident medical superintendent. The Bill also proposes that there should be qualified medical practitioners appointed by the Secretary of State as death verifiers to hold office in fixed districts and to give their whole time to the work without taking private practice. The method of certification, the duties of death verifiers, and various other matters, including rewards for persons who resuscitate apparently dead persons, are contained in 16 sections, one of which provides that the proceedings to be taken under the new law shall not be rendered unnecessary even by the fact that a coroner's inquest shall have been held. All offences against the provisions of the Bill are to be misdemeanours and one of the offences which may render a medical officer of health liable to indictment reads somewhat quaintly. He may if he thinks fit refuse permission for the body to lie in the house where death took place, in which case it will have to go to one of the mortuaries mentioned above, but "if the medical officer of health, having received such a request and undertaking as aforesaid, shall remove the body without having delivered a written statement of his reasons or shall insert in such statement frivolous or unintelligible matter, he shall be guilty of an offence against this Act." The London Association for the Prevention of Premature Burial may find the opinions of those who differ from it unintelligible and may even encounter what seems to it to be frivolity before such a Bill as that under consideration becomes law; but frivolity in a medical officer of health when performing new and responsible functions in addition to his already onerous duties need hardly be anticipated, nor are these competent and carefully selected officials likely to be unintelligible, even without the fear of prosecution to stimulate them to lucidity of expression.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 24, 1827.

I wish, however, that you would consider this point, how important a thing it is that there should be a true balance between the quantity of circulating fluids, and the powers that circulate those fluids. If *perspiration* were to be suppressed, why the blood would be redundant with water, but then in that case the kidney takes up the secretion. The kidney prepares phosphoric acid; and I suppose I need not try to convince any gentleman present that there is no phosphoric acid in the blood, if there was it would coagulate the blood; there is *soda* in it. What is there then to be said of this secretion? The albumen must be admitted to be there; it must be admitted that there is phosphoric acid in the kidney; and what are we to say with respect to that? Why, the secretion is a new formation—that the phosphoric acid is a new production; and then the question is, how is this effected? This is the grand problem proposed a long time back, and perhaps not answered, you will say, at present—How, from one kind of blood, can such dissimilar substances be got? And the old anatomists were looking to the arrangement of the vessels, to the tortuous course of the arteries and their branches, to find this out; but I defy any man to conjecture what use can result from muscular formation save that of filtration: it would spread that which was in it, but it could never make a new compound. Now Haller himself seemed to conceive that the result of these things was very much the result of vital feeling, for he has quoted the case of a hysterical female secreting nothing but colourless urine, watery urine, but he has let this nervous fit be suspended, and the kidney has again performed its functions and proper urine been secreted, more loaded too with animal substance and salts on account of the temporary suspension during the hysterical fit, therefore vital action has a great deal to do with it. But it was John Hunter who proved that vital action was the cause of all this: it was proved with respect to what we know takes place with regard to poison; a specific incision is made, a specific application of poison is made, and a specific secretion takes place. But if you were to say, how are these things prepared? I think no man in his senses can deny, but that it is by electrical operation; that electricity is the great agent of nature for the purpose of composition and decomposition of all surrounding substances, and we cannot doubt that the same agent inheres in animal bodies. A man who doubts of this, certainly could never have rubbed a black little *kitten* in the dark, or pulled off a black silk stocking in the dark; there is no doubt of electricity being thus employed. But I say it would be absurd to doubt that this was the agent for producing composition and decomposition in animal bodies after what Sir Humphrey Davy has told us. I cannot express my opinion on this subject now, in any different way to what I am accustomed to do. If any man had told me, in the early period of my life, that I should live to see chemical action explained, I should have said, well, I shall certainly not die at a less age than that of *Methusalem*. (Laughter.) But it has been done, and by Sir Humphry Davy; he showed that it depended on the matter it possessed. I was present at his lectures, when I saw performed what formed the ground of the papers that were given by him to the Royal Society, and which I had read, but the reading of them certainly did not produce that impression on my mind which the ocular demonstration of his performance did. I saw the thing done, and therefore I had conviction brought home to my mind. When I saw him make some *potash* pass through sulphuric acid, and come out potash on the other side of the dish, I said, it's wonderful! it's wonderful indeed! Why, who would have thought it! Who could have thought that a person could have mixed potash with sulphuric acid, and that it should have remained the same! Why, it is counteracting nature by using her own agents. Who could have thought it! Put potash into sulphuric acid, and what is the result? Why, that the most violent actions take place till they combine together, and then they are very sociable. On seeing this, I could not but think, that if I had been lecturing to the class Sir Humphry Davy was then lecturing to, which was principally composed of *ladies*, I should have said, now ladies, this is as wonderful as if I were to place a barrel of gunpowder before you, and, presenting you with some hot embers, you were to throw them into the powder, and they were to come through it without igniting it. Then I do not doubt but it is electrical, but electrical under the influence of the nervous system, and all the functions of the body are governed by that system.[1]

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER V.[1]

THE GRIEVANCES OF THE MEDICAL PROFESSION (*continued*).

Hospital Abuse.—The Birmingham Hospital Saturday Fund.—Working Men's Subscriptions.—The Municipalisation of Hospitals.—The Place of the Provident Dispensary.

NEXT to the evils of contract practice perhaps those of so-called "hospital abuse" weigh most hardly on the general practitioner and here, again, the subject has been so much written upon and so thoroughly threshed out that nothing more than a brief recapitulation of admitted facts is necessary. But however threadbare the subject may appear it must receive notice here, because, firstly, no record of the present state of the medical profession can be complete and, secondly, because from year to year the abuse grows and takes on fresh features, though the substance of the abuse in all instances is the same.

Hospital Abuse.

Everyone knows that many institutions which are avowedly and necessarily supported by charity admit to their wards or their out-patient departments for gratuitous advice and treatment sufferers who can pay for medical assistance. The extent to which this occurs is very large, and under such methods four sets of people are defrauded—the charitable public, the honorary staff of the hospital, the general practitioner, and the genuine poor; the charity is used for purposes for which it was not designed, the medical profession loses fees for medical service, and the class of sick persons to whom hospital aid is due is elbowed aside. The abuse is of quite old standing. 36 years ago Joseph Sampson Gamgee, the well-known Birmingham surgeon, founder of the Hospital Saturday Fund and a most liberal and enlightened thinker, pointed out the bad management prevailing in the out-patient departments of hospitals. He complained that the treatment consisted in the mere administration of physic in all cases, to the neglect of full inquiry into the cause of the disease and of well-considered advice for restoration to health; he did not mean to blame those responsible for the treatment, for he must have been aware that the circumstances which justified his words were brought about by the permanent overcrowding of the departments. Since this date the evil has grown worse. The number of out-patients attending the 92 London hospitals has been shown by Mr. C. S. Loch, secretary of the Charity Organisation Society, to have increased from 1,082,259 in 1887 to 1,448,026 in 1897 and to 1,584,987 in 1900. Mr. Loch submitted these figures to the meeting of the British Medical Association held in Manchester in 1902, at which meeting a valuable discussion took place which revealed the evil as on the increase in many parts of the kingdom, and there is no evidence to show that any arrest has taken place. The number of hospitals, particularly of special hospitals, has increased; the number of beds has been raised in existing institutions and special departments have been added, while in many cases there has been no corresponding addition made to the *personnel* of the medical staff. As a result the thorough performance of their work cannot always be expected from the medical staff and a valid excuse for the scamping of duty has been established in the very highest department of medical practice. From the north and south of England, and as much from such great towns as Manchester and Birmingham as from London, the complaints of general practitioners now come that the competition of the hospitals, especially of the *out-patient* departments of hospitals, is ruinously unfair. From the more populous centres in Scotland and Ireland, especially from Belfast, we hear the same story. The abuse has not grown up as the result of any apathy on the part of the medical profession, for general and consulting practitioners alike have seen the evil rising and have taken some measures, if no very vigorous ones, to repress it. In 1899, for example, a conference on hospital reform was promoted in London at which Sir William Broadbent, Mr. Timothy Holmes, and Mr. C. H. Warren, secretary of the Metropolitan Provident Association, spoke, as well as medical men representing such typical medical centres as Liverpool, Manchester, Birmingham, Bristol, and Brighton. The various efforts that had been made by means of inquiry into the pecuniary position of patients were detailed, the use and abuse of letters of recommendation and the charge of fees to the patients were inquired into, and the widespread nature of the evil was made manifest. The conference was not a marked success. Attendance at the meeting was small and certain of the individual speakers had no great grasp of their subject. They did not seem to recognise that hospital abuse is only one feature of a general want of organisation in the medical profession and so wasted time in proving the already proven.

Hospital abuse, like the abuse of contract practice, is an expression of the uncertainty among medical men as to their professional aims, so that what one man considers to be philanthropy another considers to be mischievous weakness. Hospitals and their medical staffs claim credit for their work and subscriptions from the public on the ground of the numbers seen at the out-patient departments. The quondam students at those hospitals and pupils of those consultants declare that their most harmful rivals in practice are just the institution and the staff from whom they have the best right to expect help. It has been said that Joseph Sampson Gamgee, in addition to being an energetic medical reformer, founded the Hospital Saturday Fund. The Hospital Saturday Fund is an admirable charity in its way, but if its developments could have been foreseen, with their bearing upon the question of hospital abuse, no medical man would have founded it. Attention has been called often to the fact that in some towns the working-class vote predominates in the management of hospitals and this is a fact the bearings of which have not yet been brought home to the medical profession. There is no reason why working men should not contribute their share to the public charities but that is not the way in which they view their subscriptions to hospitals. The public have been accustomed to subscribe to friendly societies, to medical aid clubs, to slate clubs, and to trade unions and similar institutions of all sorts. In each and every case the money which they give comes back to them in hard cash or in services rendered, and, further, they generally have a vote in the management of the funds which they thus raise. Consequently they imagine that if they support the hospitals they should not only have a vote in the management of the hospitals but that the hospitals are bound to render them services in exchange for the money subscribed. The workmen do not give to the hospitals as an act of charity but they pay so as to wipe out the charitable aspect of the institution. They propose to purchase, as it were, a right of entry to the hospital and a right to be treated, not as the recipients of charity, but as provident people who have insured themselves against the risks of sickness or accidents. This is the feeling that undoubtedly prevails, though it has not yet been formally inscribed in any document, agreement, or covenant. THE LANCET in a series of articles on hospital abuse has given a very full account of the growth and development of the Birmingham

---

[1] Chapters I., II., III., and IV. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517) and March 4th (p. 593) and 18th (p. 736), 1905, respectively.

Hospital Saturday Fund.[2] From these it is apparent that some eight years ago 75 per cent. of the workmen of Birmingham subscribed to this fund and that they raised about £15,000 in the year. There is good reason to suppose that the sum which is now subscribed by them amounts to little short of £20,000. As most of the money is raised by means of penny weekly subscriptions and as the total population of Birmingham, including women and children, is very little over half a million, it is safe to say that the vast majority of the working men are subscribers. When working men know this they must feel that they are masters of the situation, especially as with the increase of working class support there has been, and will be, a decrease in the amount of subscriptions received from the wealthier classes.

In certain industrial districts in the north of England the workmen subscribe such large sums that not only do they conceive that they are paying for the treatment they receive but maintain that they have a right to govern the hospitals. This is the direct beginning of the municipalisation of our charitable institutions, for if the majority voluntarily tax themselves to obtain control of the hospitals they will soon demand that the minority should be coerced into paying their share of the required contributions. The subscription would thus be converted into a tax and the municipal administrators would manage the general hospitals as they already manage the hospitals for the treatment of the insane and for the isolation of infectious cases. This may represent the extreme outcome of the present situation but unless the hospitals take measures to obtain the bulk of their financial support from the wealthy and well-to-do classes it is the obvious issue. And here some may say, What of it? They point to the financial condition of some noble hospitals in the centre of rich cities and ask if it would not be better to end the perpetual begging of these great charities by placing them at once upon the rates. To medical men the only answer possible is, No. When grave doubts as to the purity of hospital administration existed, as they did half a century ago, the movement towards rate-supported hospitals was a natural one. In those days the wealth of some of the hospitals, especially the London hospitals, the value of some of the lectureships, and the nepotism of some of the managers, made the suggestion of public control reasonable. Alas, that wealth has in most cases gone and with fair competition for appointments and meagre payment for lectureships have vanished the arguments for municipalisation of the charities. And it should be observed that medical opinion on this matter has been backed by shrewd and influential leaders of men, men of the unequalled social experience of His Majesty the King, men of the bottomless purses of Lord Rothschild and Mr. Beit, men of the business instincts of Sir Sydney Waterlow and the late Sir John Maple. They have all seen that the poverty of the hospitals ought to be met and allayed by charitable offering, so as to preserve the present relation of the hospitals towards the public. A big general hospital supported by the rates and therefore governed by the municipality would inevitably get out of touch with its medical officers. Men would obtain junior and senior staff appointments at the hospital for other than the excellent reason that their scientific work was the best available at the time of the vacancy; the medical profession would be unrepresented or powerless at the meetings of the governing body and would speedily find themselves unable to do their beneficent work without constant friction or submission to a position of complete subservience. Over and over again it has been demonstrated that medical work must suffer if all initiative is taken away from the medical profession, and that a hospital cannot be managed without the medical staff having a proper voice in the management. The honorary staff of a hospital under existing conditions obtain this voice; in their wards they are the main authorities, in the choice of their fellows they have much influence, and in the choice of their subordinates they have almost the power of nomination. A member of the honorary staff of a hospital feels his high and honourable responsibilities. He gives his services because he has those responsibilities and is repaid by public consideration. The public know of him that he has been chosen for his attainments and character by men of his own profession and that he is in more than a nominal sense a trustee for the conduct of a great charity. He owes it to the public, to his colleagues, and to himself to do his work without stint, and almost without exception he pays his debt. Would the public or the sick poor obtain services of the same quality if the medical staff of our hospitals were appointed by a municipal body, with all the liabilities of such bodies to political influences and social and private bias? No one who has thought about the matter can have a shadow of doubt what the answer must be.

Hospital abuse comprises under a brief title large questions, larger than have been recognised by many who have talked and written at length upon the matter. Hospital abuse is one expression of a desire on the part of the public to obtain medical assistance at the lowest possible price and it is as part of a general organised resistance to such tactics that the remedy must come. For the present the question has entered into a vicious circle and every step aggravates the difficulty. The workmen giving such large sums in the aggregate do not see that they are not contributing their just quota and are not really paying for service rendered. They give pence but think in terms of thousands of pounds. The more hospital abuse prevails the more disinclined will the well-to-do classes be to subscribe, for the knowledge is spread that the money of the charitable subscribers is being misapplied. The amount given decreases and this leads the managers of hospitals to rely more and more on the subscriptions of the working classes and to refrain from making inquiries when cases of abuse come before them. It is towards breaking this vicious circle that efforts should be directed. The agitation against hospital abuse has led to a few reforms here and there but such sporadic attempts at remedy do not meet the case. What is required is education of public opinion. The public should be helped to understand the fact that machinery to some extent really exists to deal with the whole situation only it is improperly used owing to the eccentric ignorance that prevails among all classes. An injured man or a sick woman turns at once to the nearest hospital for aid, the out-patient department becomes grossly crowded, and the real sufferers are thrust to the wall by applications for assistance justified neither by the plight of the patients nor by their circumstances. The public should be taught to regard the family practitioner as the first source of help, and where their means do not permit of their employing him in a private capacity they should avail themselves of provident dispensaries which are properly conducted and other legitimate forms of combination. The public and the general practitioner should alike regard the out-patient departments of hospitals as the poor man's consulting rooms and only such cases should be drafted to these departments as present difficulties in their treatment. Combination among the public has long been seen by the medical profession to be the solution of the problem of medical assistance for poor people; it is only unfair combination, leading to a necessary lowering of professional standards, to which objection is offered. In order that provident dispensaries may take the place of the out-patient departments of hospitals, as far as the necessitous sick are concerned, some increase in their number and some standardising of their methods are required, but if the genuine economy of a reasonable use of such institutions were more widely perceived there would be no difficulty in these improvements. The exact place of the general practitioner's surgery, the provident dispensary, and the out-patient department in a general scheme for the treatment of the sick poor should be defined and understood; then, and *perhaps then only, shall we begin to solve the problems of* hospital abuse and to remedy the evils of immoral combination. When, in addition, the public perceive that the gift of pennies, even though systematically given and amounting in the aggregate to a large sum, does not confer a legal right to obtain the gratuitous services of the staff of the hospitals, and when, as a matter of course, there is an understanding between the local practitioners and the staff of the neighbouring hospitals, whereby the practitioners may feel assured that the hospitals will not wilfully take their poorer patients from them, two of the glaring grievances of the medical profession will rapidly abate.

---

[2] THE LANCET, Sept. 18th, 1897, p. 745.

(To be continued.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8920 births and 4740 deaths were registered during the week ending March 18th. The annual rate of mortality in these towns, which had been 15·7, 17·1, and 17·2 per 1000 in the three preceding weeks, declined again to 15·8 per 1000 last week. In London the death-rate was 15·6 per 1000, while it averaged 16 0 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3·9 in Bournemouth, 7·8 in Walsall, 8·1 in Hornsey, 8·4 in Grimsby, 8·5 in Walthamstow, and 9·0 in King's Norton; while the highest rates were 22·3 in Rochdale, 22·7 in Southampton, 22·8 in Middlesbrough, 23·9 in Stockton-on-Tees, 25·1 in Barrow-in-Furness, and 27·4 in Portsmouth. The 4740 deaths in these towns last week included 430 which were referred to the principal infectious diseases, against 365 486, and 471 in the three preceding weeks; of these 430 deaths, 181 resulted from measles, 108 from whooping-cough, 45 from diphtheria, 41 from diarrhœa, 36 from scarlet fever, 17 from "fever" (principally enteric), and two from small-pox. No death from any of these infectious diseases was reg[illegible] nemouth, [illegible] on, Coventr[illegible] he highest [illegible] West Bromw[illegible] on-on-Tees, [illegible] nal mortality from measles occurred in Portsmouth, Southampton, West Bromwich, Leicester, Nottingham, St. Helens, Bolton, Sheffield, York, Middlesbrough, Stockton-on-Tees, and West Hartlepool; from whooping-cough in Willesden, Tottenham, and Preston; and from "fever" in West Bromwich. The mortality from scarlet fever, from diphtheria, and from diarrhœa showed no marked excess in any of the large towns. One fatal case of small-pox was registered in South Shields and one in Tynemouth, but none in any other of the 76 towns. The number of small-pox patients [illegible] treatment in the Metropolitan Asylums [illegible] th, was 33, against 16, 15, a[illegible] preceding weeks: nine new cases were admitted during the week, against seven, four, and three in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 1987, 2002, and 2036 at the end of the three preceding weeks, had further risen to 2042 at the end of last week; 262 new cases were admitted during the week, against 224, 290, and 303 in the three *preceding* weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 335, 353, and 361 in the three preceding weeks, declined again to 304 last week, and were 71 below the number in the corresponding period of last year. The causes of 63, or 1·3 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, West Ham, Leeds, Hull, and in 42 other smaller towns; the largest proportions of uncertified deaths were registered in Ipswich, Birmingham, Coventry, Liverpool, St. Helens, Manchester, Sheffield, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·3, 17·4, and 18·6 per 1000 in the three preceding weeks, declined again to 18·2 per 1000 during the week ending March 18th, but was 2·4 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·5 in Leith and 12·2 in Paisley to 19·6 in Aberdeen and 22·3 in Greenock. *The 610* deaths in these towns included 17 which were referred to whooping-cough, 13 to diarrhœa, ten to measles, eight to diphtheria, three to "fever," and one to scarlet fever, but not any to small-pox. In all, 52 deaths resulted from these principal infectious diseases last week, against 63, 60, and 58 in the three preceding weeks. These 52 deaths were equal to an annual rate of 1·6 per 1000, which was 0·2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 27, 27, and 31 in the three preceding weeks, declined again last week to 17, of which 13 occurred in Glasgow and two in Greenock. The deaths from diarrhœa, which had been 16 and 17 in the *two preceding weeks, decreased to 13 last week and included* five in Glasgow, four in Dundee, and three in Edinburgh. The fatal cases of measles, which had been seven, eight, and six in the three preceding weeks, increased again last week to ten, of which seven were registered in Glasgow and three in Edinburgh. The deaths from diphtheria, which had been, six, two, and three in the three preceding weeks, further rose to eight last week, and included fo[illegible] Glasgow, and two in Paisley. T[illegible] which had been eight, four, and [illegible] weeks, rose again to three last week, and included one case of typhus in Aberdeen. The deaths referred to diseases of the respiratory organs in these towns, which had been 116, 114, and 153 in the three preceding weeks, declined again to 140 last week, and were 45 below the number in the corresponding period of last year. The causes of 14, or more than 2 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·5, 30·7, and 25·2 per 1000 in the three preceding weeks, further fell to 23 8 per 1000 during the week ending March 18th. During the past four weeks the death-rate has averaged 26·3 per 1000, the rates during the same period being 16·5 in London and 15·7 in Edinburgh. The 173 deaths of persons belonging to Dublin registered during the week under notice were 10 below the number in the preceding week, and included eight which were referred to the principal infectious diseases, against five, eight, and two in the three preceding weeks; of these, four resulted from measles, and one each from scarlet fever, from diphtheria, from "fever," and from diarrhœa, but not any from small-pox or from whooping-cough. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·0 in London and 1·7 in Edinburgh. The fatal cases of measles, which had been three, three, and one in the three preceding weeks, rose again last week to four. The 173 deaths in Dublin last week included 26 of children under one year of age and 47 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week. Two inquest cases and two deaths from violence were registered; and 62, *or more than a* third, of the deaths occurred in public institutions. The causes of 11, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: R. Hardie to the *Egmont* and for Malta Dockyard; H. W. A. Burke to the *Commonwealth* on commissioning; E. B, Pickthorn to the *President*, for three mo course; R. T. A. Levinge to the *Montagu;* and J. F. Hall to the *President*, to be lent to R.N. Rendezvous temporarily. Surgeons: A. C. Bean to the *President*, for three months' hospital course; H. C. Ross to the *Commonwealth;* and L. Lindop to the *Ganges.*

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel C. White (retired), now re-employed at St. John's Wood Barracks, will revert to retired pay in May and until then has been granted sick leave. Lieutenant G. S. C. Hayes and Lieutenant C. Bowle have left for a tour of duty in India. Lieutenant-Colonel J. M. Reid has been appointed Medical Inspector of Recruits on the staff of the Southern Command and has been posted to the Administration Headquarters, Radnor House, Salisbury. Lieutenant-Colonel H. Scott (retired), A.M.S., has been transferred from Yarmouth to London for duty in connexion with the recruiting staff. Major M. L. Hearn has been appointed Senior Medical Officer, North China.

IMPERIAL YEOMANRY.

Montgomeryshire: Surgeon-Captain F. E. Marston resigns his commission (dated March 18th, 1905).

VOLUNTEER CORPS.

The Electrical Engineers (Volunteers): Surgeon-Lieutenant C. H. Leaf to be Surgeon-Captain (dated Feb. 28th, 1905).

Rifle: 1st Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Captain R. J. Swan, from the 1st Surrey (South London) Volunteer Rifle Corps, to be Surgeon-Captain (dated March 18th, 1905). 1st Volunteer Battalion the Suffolk Regiment: Supernumerary Surgeon-Major G. S. Elliston [illegible] Senior Medical Officer, [illegible]) to be Surgeon-Lieutenant-Colonel and to remain seconded (dated March 18th, 1905). 4th [illegible] Volunteer Battalion the Sherwood Fo[illegible] and Derbyshire [illegible] F. H. Appleby [illegible] -Colonel, Senior Medical Officer, [illegible] unteer Infantry Brigade) to be [illegible] and to remain Supernumerary [illegible]

THE ROYAL NAVAL COLLEGE, OSBORNE.

The Medical Consultative Board of the Admiralty, consisting of Mr. G. H. Makins, C.B., Dr. W. H. Allchin, and Dr. H. D. Rolleston, accompanied by Mr. J. H. Fisher, has visited Osborne College to report upon the existence of a mild form of conjunctivitis which has been prevalent among the boys. The Director-General of the Royal Navy Medical Service was also present and it is gratifying to know that the conjoint report in regard to the sanitary state of the College was highly satisfactory.

COLOUR BLINDNESS AND THE ARMY AUTHORITIES.

According to a recent ruling of the War Office which has appeared in the press it seems that colour blindness will no longer be a bar to a candidate seeking a commission in His Majesty's army. Previously to the promulgation of this order the reverse was the case. Colour blindness was regarded as a disqualification and those who could not pass the requisite colour tests failed at the required medical examination. It seemed but reasonable to suppose that the War Office authorities knew what they were about and that colour blindness might have been found to interfere with an officer's duties on field service, in the matter of signalling, for example; but whether it did or did not or was likely to have that effect was a point which should obviously have been settled in the first instance and before any order on the subject was issued. As it is, a number of army candidates have been rejected by medical boards in the past who need not have been had the present ruling been in force, whereat the rejected candidates and their parents and guardians naturally feel aggrieved and complain.

RECRUITING IN GERMANY IN 1903.

An abstract of the report on recruiting for the German army in 1903, which was presented to the Reichstag on Nov. 20th last, appears in the *Archives de Médecine et de Pharmacie Militaires* for the current month. The total number of young men whose names were inscribed on the lists for examination by the various recruiting boards throughout the country during the year 1903 was 1,072,819. Of these, 125,000 either refused to appear or could not be found, 1167 were excluded, 41,828 were discharged, 478,164 were sent back subject to re-examination in the following year, 28,769 had already entered either the army or the navy as volunteers, while 397,891 were accepted as fit for service. The distribution of the latter was as follows: Landsturm, 98,992; army reserve, 82,786; navy reserve, 1329; active army, combatants 203,913, non-combatants 3670; active navy, combatants 4337, non-combatants 2864. The total number of volunteers during 1903 was as follows: army, 49,226; navy, 3381. Education in Germany has advanced of late years. Twenty years ago 2·03 per cent. of the recruits were illiterate; in 1903 the general percentage was only 0·05. Western Prussia furnished the highest percentage (0·25), next to it came Eastern Prussia (0·16), then Posen and Brandenburg (0·03), while in Pomerania the percentage of youths unable to read and to write was no more than 0·01.

THE WAR IN THE FAR EAST.

There is a comparative lull in the fighting in the Far East at the present time with practically no news from Manchuria. There are signs of exhaustion on both sides and time is required to get up the necessary supplies and remove the sick and wounded towards their respective bases. The pursuit of the Russian army to Harbin nevertheless continues but it seems doubtful whether the Japanese can pass their enemy on the way there. All the accounts that have been published descriptive of the occurrences that followed the evacuation of Mukden agree in the breakdown of the Russian medical and hospital arrangements and the consequent terrible sufferings of the sick and wounded, to say nothing of those who were starving and exposed to cold owing to the inadequacy of the commissariat and transport to cope with the stress and strain of the situation. The inevitable congestion, too, on the Siberian line has of late become terrible and the supply difficulty must be an ever-increasing one for the Russian forces in the field.

M. V. D. Bidrin, the manager of the Moscow Red Cross contingent at the seat of war, has telegraphed to his committee that in obedience to a special request he had detached an operating wagon and sent it to the extreme limit of the railway near Fushun. During six days as many as 60 operations that could not be delayed were performed in it. The detachment, consisting of the lady doctor Gedroitz and the sisters of mercy Bikovoi, Ponomarevoi, Zacharovoi, and Rosenplater, worked for 20 hours out of the 24 and refused to leave in spite of his warning that they might be cut off. All remained till the last moment.

THE WOUNDS INFLICTED BY THE JAPANESE SMALL-BORE RIFLES.

In a late number of the *Vratch* Dr. J. Seldowicz gives an interesting account of his experience while acting as surgeon in chief of No. 10 hospital at Tieling in Manchuria. His observations with reference to the injuries inflicted by the Japanese small-bore rifles confirm the deductions in favour of conservative surgery in such cases which were drawn during the South African war. His hospital was sufficiently close to the field of battle to admit of the reception of the wounded soldiers while they were still retaining the dressings that had been applied at first-aid stations. On June 4th last a train reached No. 10 hospital at six o'clock in the morning containing 150 men who were wounded on June 2nd in an engagement at Wafankoo. They had been compelled to find their way as best they could on foot for between 20 and 30 kilometres and had then to support a journey by rail of nearly 300 more. In spite of this and notwithstanding the fact that many among them had penetrating wounds of the thorax and of the abdomen, their general condition was excellent. At first sight it seemed as though they were merely slightly injured. On further examination operative interference was found to be necessary in five cases only. Four men with projectiles superficially lodged were relieved of them under cocaine, while the fifth had a crushed finger amputated. Penetrating wounds of the thorax were treated simply by antiseptic dressing, with rest and the internal administration of codeine. In some instances it was clear that the lung was implicated but the patients nevertheless did well and ultimately recovered perfectly. Dr. Seldowicz consequently feels disposed to classify penetrating gunshot wounds of the thorax among favourable injuries. In three cases where the pelvis was entered a similar conservative course of treatment was adopted with equal success, although in one of them the cavity of the abdomen had also been entered by the projectile. Wounds of the buccal region did well likewise under simple antiseptic measures, notwithstanding the proneness to suppuration so often seen when the mouth has been injured. Several of the invalids had joints more or less shattered by bullets but all recovered with useful limbs. Finally, Dr. Seldowicz comes to the conclusion that the projectile of the Japanese small-bore rifle may be classified as a "humanitarian" projectile, the effects it produces in the human organism being generally unattended by grave disorder.

RUSSIAN MEDICO-POLITICAL MANIFESTO.

On March 8th at the close of a sitting of the St. Petersburg Society of Hospital Doctors (called to consider the threatened invasion of cholera), which was numerously attended, the society carried a threefold motion setting forth that only a united society could hope to cope successfully with the expected invasion of cholera; but that the present conditions paralyse united action and make it impossible to arrest the scourge or to limit the number of its victims; that serious consequences of such a visitation are only to be feared on account of distrust in society which cannot be removed because of the limitations to which the press is subjected and of the absence of freedom of speech; and that more dreadful and extensive cholera riots may occur than in 1892 and that the most important immediate question is the introduction of radical reform.

It is notified that the promotion of an officer of the Indian Medical Service to the rank of major may be accelerated if he produces, while in the rank of Captain, satisfactory evidence of progress in any branch of knowledge which is likely to increase his efficiency, such as obtaining a higher degree or a special qualification of repute, or by furnishing proof of having pursued with diligence and advantage serious study of an approved subject. The period of acceleration that may be granted is fixed at six months provisionally.

It has been decided that the London Military District shall be provided with a completely equipped bearer company and field hospital for training all ranks of the Royal Army Medical Corps in field duties.

APPARENT RECOVERY FROM PRESUMABLY MALIGNANT DISEASE OF THE MOUTH.

To the Editors of THE LANCET.

SIRS,—I have read with interest the case of malignant disease of the mouth reported by Dr. W. Gordon of Exeter in THE LANCET of March 18th, p. 713, having seen a case of apparent epithelioma of the tongue in my practice last year which disappeared entirely and the patient died subsequently from other causes. Unfortunately, as in Dr. Gordon's case, I was unable to have a portion of the growth submitted to microscopical examination.

The following brief notes of the case may be of interest. It occurred in a lady, aged 98 years, totally blind from cataract, toothless, and bed-ridden for the past six years. The beginning of June last year she complained of sore throat, the fauces were very red and swollen, as was also the tongue. She complained of difficulty in swallowing, which caused her much pain, the pain shooting into the ears, especially into the left ear. There was no enlargement to be found of the submaxillary or cervical glands. A small ulcer appeared on the side of the middle third of the tongue on the left side about three millimetres in diameter. I was from home the last fortnight in June until the end of the first week in July and on my return found a ragged ulcer, two-thirds of an inch in extent and a quarter of an inch deep, on the site of the previous small ulcer, with hard cartilaginous borders, the outer border being especially raised and hard. My locum-tenent and I diagnosed the growth to be malignant and this opinion was confirmed by one of the leading Birmingham surgeons who pronounced it as a case of epithelioma and, taking into consideration the age of the patient, agreed that operative interference would not be advisable. The only treatment adopted was boric acid mouth washes and painting over the painful parts with 5 per cent. of glycerine of [illegible] To make a long story sh[illegible] appeared and all the painful [illegible] and throat being normal by the beginning of November. The patient subsequently died at the end of December from general failure.

The question naturally arises, Is it possible that well-marked cancer may disappear spontaneously in some cases irrespective of so-called specific or other methods of treatment? and if so, Are there other authenticated cases on record?—questions which might well be answered by those who have special exp[illegible]

I ar[illegible]

[illegible] OSHUA.

Great Malvern, March 20th, 1905.

EXCESSIVE URIC ACID AS A CAUSE OF MIGRAINE.

To the Editors of THE LANCET.

SIRS,—I have read with great interest a paper by Dr. W. A. Turner on the Nature and Treatment of Epilepsy in THE LANCET of March 18th but would crave a few lines to point out that he is not quite correct with regard to some of the facts as known to me and that in a paragraph near the end of his paper he comes within measurable distance of contradicting himself. On p. 710 he says: "Haig suggested that there was a definite relation between excess of uric acid in the blood and such maladies as migraine and epilepsy, but treatment directed upon this theory has not proved of greater value than other methods of treatment [illegible]" [illegible] that in my experience [illegible] somewhere between 500 and 1000 cases, I should not be over the mark if I said that in all who carried out the treatment correctly for a sufficient length of time the successes amounted to 75 per cent.; in fact, I only know of as many cases as I could count on the fingers of one hand where diet treatment has failed and these, I believe, merely require further investigation to demonstrate the cause of its failure. Then it has been acknowledged by others that abstinence from meat cures migraine.[1] With regard to epilepsy I have had far less experience, but here again among cases which come under treatment in the early years of their trouble quite a large percentage have been completely cured, and of those that come at various later periods many greatly improve, so that both in the diminution of the frequency and severity of the attacks and in the power to dispense altogether with bromides the good results have practically paralleled very closely those with migraine.

On p. 711 Dr. Turner says: "The dietary which has been found most serviceable consists of milk, fresh butter, eggs, fruit, vegetable[illegible] as far as possible eliminated." [illegible] the single exception of e[illegible] white, or even the whole [illegible] is exactly the diet that I have for years been advocating and I should thoroughly agree with him as to the elimination of salt from the food. It is my constant practice to leave it out not only in migraine and epilepsy but in all uric acid troubles and in many of those who live on my diet the desire for salt more or less quickly disappears.

I am, Sirs, yours faithfully,

ALEXANDER HAIG.

Brook street, W., March 20th, 1905.

THE CLASSIFICATION OF INSANITY.

To the Editors of THE LANCET.

SIRS,—To follow Dr. Goodall through his very detailed criticism of the articles on kinds of insanity, &c., that I have been contributing to the *Journal of Mental Science*, would occupy an amount of your space that I can scarcely expect you to place at my disposal, even if it were worth while. Dr. Goodall sets himself to prove that I am inconsistent. By taking a few words here from an author's one book, and a few words ther[illegible] the passages from their con[illegible] not difficult to show that a [illegible] writer I know, who is likely to come consistent through such a trial, is Euclid. And when it is done, what is achieved? The writer is shown to be inconsistent. But perhaps he considers consistency a virtue of low rank in comparison with candour. Perhaps he thinks that it shows less courage and less honesty to maintain with obstinacy an opinion once expressed, than frankly to admit that he has been mistaken. Dr. Goodall contrasts bits of the classification proposed in my articles with bits of the classification formerly proposed in my text-book, and shows that the two are inconsistent. Sirs, they are inconsistent. Dr. Goodall omits to mention that, in these articles, I have myself subjected my own previous classification to destructive criticism, and discarded it. It is not wonderful if the two classifications disagree. Further, criticism directed against my second classification, and making no reference to the purpose of the classification, is misdirected. The articles dealt with certain statistical tables. The classification was made to fit these tables. Things are excluded from the classification, not because they are necessarily inappropriate to some classification, but because they appear in others of the tables criticised, and are therefore redundant in this classification; or because they do not admit of trustworthy statistical treatment. In short, the classification is offered *secundum quid*, and Dr. Goodall treats it as if it had been offered *simpliciter*, a device of notorious fallacy. Dr. Goodall sneers at my statement that "often, but by no means always, there is a septic element in the case" of insanity connected with the puerperium, and implies that I ought to have given exact figures. As he appears to have read my articles, he might have gathered from them that I have no great confidence in the statistics hitherto collected; and one of the sets of figures, given by him in reproof of my inexactness, is worthless on the face of it. He contrasts the "full and orderly" description of senile insanity, given by Weygandt, with my "attenuated" description of the same. My text-book was avowedly written, not for psychiatric experts, but to give to students of general medicine a succinct account of insanity. In such a book a "full" description would be out of place. If Dr. Goodall intended to imply that my "attenuated" description is also disorderly, it would have been more candid to say so, and to point out the disorder. In the pursuit of science, little is gained, I think, by epithetical criticism.

I am, Sirs, yours faithfully,

March 18th, 1905. CHAS. MERCIER.

TO MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—May I through the medium of your widely read columns appeal to medical men, and more especially to medical Freemasons, who are subscribers to the different Masonic charitable institutions for their votes and influence on behalf of the candidates whose names are given below and who are up for the next elections in April and May? The response to similar appeals in THE LANCET in the past has been so liberal as to lead us to hope that all the candidates may be successful. The votes so collected should reach such numbers as to insure this complete success and by organisation alone can such a result be obtained. It is with the object of thus organising the collection and distribution of votes that this appeal is made by the St. Luke's Medical Lodge of Instruction and is supported by the London Hospital Lodges' Joint Committee. Certainly the candidates have especial claims upon medical Freemasons and any votes on their behalf will be gratefully received by our treasurer, Dr. J. Eyre, Wandle House, Wandle-road, S.W., or by myself.

Royal Masonic Institution for Girls (election on April 13th).—Eileen Torrens, daughter of the late James Torrens, M.D., M.Ch., of Bridgnorth, Salop; and Mary Trevor Webster, daughter of the late Trevor Webster of Bawdley, Worcestershire.

Royal Masonic Institution for Boys (election on April 14th).—Alfred Montague Burns, son of the late Alfred Hugh Burns, L.R.C.P. Irel., L.S.A., of Margate; Charles Robert Hughes, son of the late David Arthur Hughes, M.R.C.S., L.R.C.P., D.P.H., of Barmouth, N. Wales; and Cyril Ernest Hockley, son of the late Edward Robert Hockley, surgeon dentist, of Northfleet, Kent.

Royal Masonic Benevolent Institution for Aged Freemasons and Widows of Freemasons (election on May 19th).—Joseph Rickets, L.R.C.P., L.M. Edin., L.F.P.S. and L.M. Glasg., of 8, Hornby-avenue, Bootle; Elinor Gartley, widow of th late John Alexander Gartley, dental surgeon, of Glouceste road, Kew.—I am, Sirs, yours faithfully,

HAROLD S. SINGTON,
Secretary, St. Luke's Medical Lodge of Instruction.
44, St. Mary's Mansions, W., March 14th, 1905.

PERITONITIS: A BACTERIOLOGICAL STUDY.

To the Editors of THE LANCET.

SIRS,—In view of the interesting results obtained by M L. S. Dudgeon and Mr. P. W. G. Sargent in their bacteri logical study of peritonitis I feel disposed to ask a questi of them. Do they regard their results as disproving th possibility of an appendicitis due to the bacillus influenza Several clinicians have attempted to classify some cases appendicitis (or perityphlitis) as of influenzal origin, an have suggested that such may in part account for the allege increased prevalence of the complaint. In this connexion discussion at the Académie de Médecine on July 5th, 1904, is of interest, as is also an observation by Mr. H. C. Allinso of King's Lynn on a case of extreme congestion in th cæcal region which he considered to be of influenzal origin.[1]

Perhaps the cases examined by Mr. Dudgeon and M Sargent were not such as might even have been su pected to be of influenzal origin. Perhaps the cultur methods adopted were not such as would favour the growt of the bacillus if present. But some of us must have not of cases which make us unwilling to give up the theory th as the influenza bacillus may cause severe gastric symptom so it may at times cause an appendicitis.

I am, Sirs, yours faithfully,

A. CHRISTIE REID, M.B., Ch.B. Aberd.

Thurnscoe, near Rotherham, March 14th, 1905.

THE REMISSION OF INCOME TAX O INSURANCE PREMIUMS.

To the Editors of THE LANCET

SIRS,—In THE LANCET of March 11th, p. 663, there appea an article entitled "Hints on Income Tax Assessment," in th course of which your contributor mentions the deduction income tax from insurance premiums. I beg leave to ca your attention to the following sentences which occur in h paragraph on this subject. "It is important to notice this connexion that it is only premiums paid to an Engli insurance company or to an approved colonial compa which may be deducted. Thus a premium paid to American or other foreign company would not be allow for."

This statement is, unfortunately, misleading, althoug absolutely correct as far as the Inland Revenue authoriti are concerned. The British Government, for reasons be known to itself, chooses to remit the income tax only home and colonial office premiums. But I am sure that fairness you would wish to complete the information yo have given by letting your readers know that my ow company, the Mutual Life Insurance Company of Ne York, offers the same benefits and grants the sa privileges as regards income tax to its policy-holders they would receive if insured in a purely British compan I am well aware that the recovery of income tax is important consideration to many people when taking o insurance policies and it is for this reason that I take t opportunity of correcting a statement which is apt to crea a totally wrong impression in the minds of your readers regards the Mutual Life Insurance Company of New York.

I am, Sirs, your faithfully,

D. C. HALDEMAN,
General Manager.

March 18th, 1905.

*** We publish Mr. Haldeman's letter but he is n justified in calling our remarks "misleading." A compan by private arrangement with its clients, may place the clients in any position that it likes. The general regulatio of the Inland Revenue authorities remain as we quot them but there is nothing to prevent a company from co tracting itself outside the regulations.—ED. L.

THE MEDICAL CONTROL OF SCHOOLS AT NEW YORK.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

IN spite of the ever-increasing influx of immigrants and the consequent crowding and overcrowding the city of New York can boast of a decreasing death-rate. Of course, many causes contribute to bring about this happy result. It is, however, quite safe to say that of the various measures taken the most recent and probably the most successful are those which have for their object the prevention of schools becoming centres of infection and of contagion. In England the President of the Board of Education has appointed, with the concurrence of the President of the Local Government Board, an inter-departmental committee not only to inquire into the feeding of school children but also "to ascertain and report on what is now being done, and with what result, in respect of medical inspection of children in public elementary schools." In these circumstances the experience acquired at New York on almost identically the same lines is likely to prove of use and of interest. The elaborate series of precautions now enforced at New York were not devised in a day. As is usually the case in such matters they were slowly evolved and extended as experience proved the need of each successive development. It was in March, 1897, that the medical supervision of the schools of the city of New York was placed under the control of the department of health. This is the equivalent to placing the sanitary control of schools in England under the medical officer of health and the health committee of the borough or town council. In October, 1896, the New York sanitary authorities caused an investigation to be made and a report to be presented on the influence exercised by schools in the spread of epidemics. The homes of the children absent from school were visited. It was then ascertained that many of these absentees were suffering from infectious or contagious diseases. There was also and not infrequently good cause to suspect that the complaint had been caught while attending school, particularly as other members of the same household were found to be at school in spite of the sickness which prevailed in their homes. In some cases of diphtheria a child would return to school as soon as the more acute symptoms had disappeared. Some of these children were traced to school and a culture was taken from the throats of those who had returned to school because they were suffering only from slight sore-throat. Bacteriological examination clearly revealed the presence of the Klebs-Löffler bacilli. The same danger occurred in regard to scarlet fever and, with the inquisitiveness of children, it was found that the peeling from the hand had been passed round a class-room for inspection.

The report containing these and many other conclusive facts was submitted by the board of health to the board of estimate, or presumably what would be called in England the finance committee of the county or borough council. The finance authority with commendable promptitude voted a subsidy sufficient to pay 150 inspectors at a salary of £6 per month. These inspectors had one or two schools to visit each school day at about 9.30 A.M. As the children arrive at the school the teachers stop and send to an office any child whom they suspect of being unwell. The children thus detained do not enter the class-room but are kept in a sort of quarantine till the arrival of the inspector. The schools are all connected by telephone with the central offices of the department of health. The school inspector on examining the children detained by the school teachers is thus able to telephone to headquarters, so that a physician may be sent at once if there seems to be a case of contagious disease. If the suspicions first of the school teacher and then of the inspector are confirmed by a medical officer sent by the department of health the authorities of the school are duly informed so that they may exclude all members of the patient's family and inspectors visit the child's home to see that the patient is properly isolated. A district sanitary inspector then takes over the charge of the case which he has to visit at least once a week. The sanitary inspector shows the family how they are to isolate the patient and pastes a notice on the door of the apartment warning all who may be about to enter as to the nature of the contagion within. Further, it is the duty of the inspector to call on all the other [illegible] them of [illegible] family a[illegible] sleeps at the back and close to a shop or place of business the patient must be removed to the hospital or the business closed. In either case the premises must be fumigated before business is resumed. When the patient is sent to the hospital then the other children may go to school after the disinfection of their home. But such regulations would be set aside by many thoughtless or ignorant people if there were no stringent means of enforcement. At New York, if the patient is allowed to leave the room where he is isolated or the shop is opened for business, or if the notice is removed from the door, a police officer—and there is a special corps of policemen known as the health squad reserved for such purposes—is appointed to watch over the case. He puts up another notice which has an addendum to the effect that the patient will be forcibly removed if there is any further infringement of regulations. This seems a rather mild proceeding. In England wilful exposure of infected persons may be punished by a fine not exceeding £5 and imprisonment not exceeding three months. Yet it is stated that forcible removal of such cases to a hospital is not a frequent occurrence at New York.

If the school inspector suspects the presence of diphtheria he has with him all that is necessary and at once takes a swab from the throat or nose. On a blank form, likewise ready to hand, he inscribes: (1) the number of the swab, whether it is the first, second, or third specimen taken; (2) the school number; (3) the date on which the swab was taken; (4) the name of the child; (5) the address of the child; (6) whether exudate is present in the throat; (7) how long sick; and (8) the address, the name, and the telephone number of the school inspector. The child is, of course, excluded from school till the answer has been received from the bacteriological laboratory. The specimens are taken in the morning and therefore are in the hands of the bacteriologists by 2 P.M., when the examination commences. There are two culture slips. Each is affixed to a separate tube and kept in an incubator all night. The next morning they are examined and according to the result marked "L. present," or "No L.," or "Doubtful, another culture required." In the latter case, of course, the pupil is not allowed to return to school till the further examination is completed. Formerly all such protective measures depended on the acuity of the school teachers and they rendered great service but had not the necessary authority to exclude doubtful cases. Now, on the contrary, the medical inspectors very rigorously exclude these doubtful cases. Also carefully prepared lists are sent every day to every school so that the teachers may see at a glance all cases reported to the department of health and find if any are likely to attend their schools. If a child from an infected home is present the fact is thus at once detected and the child is immediately sent away. In this manner the children have been to a large extent protected from contact with such diseases as measles, diphtheria, scarlet fever, and so forth. Under this system and during the school year, September, 1901, to June, 1902, consisting of 194 school days, 47,679 visits were paid to 266 schools, with an average attendance of 260,182 pupils. Of these 87,730 were examined and 9703 were excluded from the schools. The diseases and complaints reported were as follows: measles, 85 cases; diphtheria, 94; scarlet fever, 34; whooping-cough, 174; miscellaneous, 526; contagious [illegible] and body, 4125; [illegible] miscellaneous

The great defect of this system is [illegible] first and most difficult diagnosis depends upon the perspicacity of the school teacher. It is the correctness of the earliest diagnosis which alone can save the school from the danger of infection and yet it would be manifestly unfair to blame a school teacher if he failed to detect early symptoms. Therefore a better organisation was planned and put into operation in September, 1902. Inspectors were appointed, approximately one inspector for every 5000 children. If the distance between the schools is greater than usual then a smaller number of children are assigned to the inspector of such a district. Each inspector has to visit all his schools before 10 A.M. He then has to examine all children isolated by the teacher for fear that they may be sickening with some contagious disease. He must further examine all children who have been absent from school for a few days and all children excluded from school attendance. When this is terminated the inspector proceeds with his periodic inspection of all the children. This inspection is carried forward under certain fixed regulations. The inspector must on entering a class-room place himself with his back to a window. The children then march past him in single file. On no account must he touch any of the children. The children are taught to pull down their own eyelids and to open their mouths wide. If there is anything suspicious the children are sent to the office, where they are subsequently and thoroughly examined. Thus there are two sorts of examination, first, that of the children who are suspected of being ill and consequently have not been allowed to enter the class-room; and secondly, that of the children who are believed to be in good health and who are in the class-room. The latter are not inspected every day. The inspectors visit each day different class-rooms and so divide this work as to be able to see every apparently healthy child about once a week. When there are any signs of measles, scarlet fever, diphtheria, small-pox, varicella, whooping-cough, rötheln, mumps, or acute catarrhal affections of the eyes, nose, and throat, the pupil is given an exclusion card on which are inscribed his name, age, residence, and the number and address of his school. This card is placed in a special envelope provided by the department of health and sealed. With this the child is sent home and no one but the parents or the guardians of the pupil has the right to open the envelope. In cases of measles and scarlet fever the school inspector telephones to the central office of the department and a medical officer is despatched by the sanitary authority to confirm or otherwise the school inspector's diagnosis and thus to justify the subsequent rigorous measures which have to be enforced and which have been described above. The inspector must also visit at their own homes all children who have been absent for a few days from school for no known and sufficient reason. By this means a great number of unreported cases of contagious disease are discovered. Thus by visiting absentees from Nov. 2nd, 1903, to May 12th, 1904, no less than 561 cases of measles and 107 of German measles were discovered, together with 70 cases of scarlet fever, 81 of chicken-pox, 19 of diphtheria, 25 of whooping-cough, 24 of mumps, two of pneumonia, and three of typhoid fever.

While the school inspectors thus penetrate into the homes of absentee pupils and often make useful discoveries, other inspectors not connected with the schools, such as the tenement house inspectors, also report any case of contagious disease which they may encounter to the department of health which in its turn warns the school authorities. In this manner many more cases have been reported, so that, judged by the statistical results, it would seem as if there had been a considerable increase in sickness. But as the death-rate does not increase in proportion it may safely be inferred that there has only been increased efficiency in notifying cases and not in the actual number of cases. Of the enormous amount of work done the following figures give an idea. For the school year 1902–03 there were 188 days during which a daily average of 287,592 pupils attended 263 schools. These schools were visited 62,298 times, the pupils were examined 6,236,336 times, and 41,826 were excluded in consequence of ill health. The diseases for which these children were excluded were 510 suspected cases of diphtheria of which 416 proved to be true cases. There were 45 cases of suspected scarlet fever of which 22 were genuine. Measles gave 94 true out of 168 suspected cases and varicella 528 out of 673 pupils excluded. Then there were 201 cases of pertussis, 4728 miscellaneous cases, 8678 cases of pediculosis, 25,264 cases of contagious eye diseases, and 1561 of contagious skin diseases.

Perhaps one of the greatest practical difficulties is the presence of vermin. Thus the very complete and able report of the New York city department of health on the question of the schools states that on the first day at the beginning of the year for which the figures have just been given no less than 1886 children were sent away for pediculosis. This, it is pointed out, caused the greatest indignation among the parents. Those parents whose children had been excluded were angry and those whose children had not been excluded were still more angry, so that everybody was discontented. The majority of the parents were indignant that their children should be brought into contact with other children whose heads were not clean. So great was the clamour that the authorities started an investigation in order to ascertain what precautions were taken to separate
the children's outer garments. It was found that the accom
modation provided was far from satisfactory. The idea
would be a separate wardrobe locker for each child and i
default it was suggested that it would be better for eac
pupil to put his overcoat on a shelf under his desk than t
hang it up promiscuously on pegs with other children'
clothing. As a result of the publicity given to this questio
some improvements are taking place. Then the prevalenc
of contagious diseases of the eye led to inquiries as to th
methods employed for keeping free from infection the pens
pencils, and drawing materials used by the pupils. Eac
school inspector received the following form which h
was requested to fill up: "School number. Number o
classes in school. Number of classes using envelopes
Number of classes using antiseptic pencil-holders. Numbe
of classes using individual boxes or bags. Number of classe
in which each pupil has his or her own pencil; no collectio
or distribution at all. Number of classes in which pencil
are marked for identification but collected in a common box
Number of classes in which pencils are collected and distribute
indiscriminately each day." The information obtained i
response to these questions was not encouraging. Th
majority of the principals and the teachers had neve
thought of these questions at all. They had not displaye
any concern as to the care of pencils, &c., from the sanitar
point of view. But there were some teachers who used i
their own classes modern contrivances for keeping separatel
each child's writing materials. For this purpose the depart
ment of health recommends the use of a large manilla en
velope. The child's name can be written on the outside. Thes
envelopes are distributed to their owners at the beginning o
the class and the pencils, &c., are placed inside after th
class is over. When this is done and the envelopes are fastene
with a clasp they can be collected and stored away. But i
is preferable for each child to have a drawer in his desk an
to place the envelope in that drawer. In consequence of th
report which had been drawn up when the inspectors ha
filled in the form quoted above the Board of Educatio
purchased a large quantity of manilla envelopes, distribute
them to the teachers, and called upon them to see that th
pupils' pens and pencils were kept inside these envelopes an
not mixed together. As for the school books, those that hav
been used by children suffering from contagious disease mus
all be destroyed. Thus much greater care is now take
to prevent school materials, books, pencils, &c., becoming
vehicles for the transmission of disease.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Hospitals: Annual Reports.

THE 125th annual report of the General Hospital wa
presented to the governors on Wednesday last. An advers
balance of £1297 on the year's working was reported despit
the fact that, through the generosity of Sir John Holde
who has provided a laundry at Erdington, the annual ex
penditure on washing has been considerably curtailed. Th
deficit was attributed to a falling off in the subscriptions an
to the new method of distributing the Hospital Sunda
Fund. Formerly the hospital received every third year th
whole sum subscribed during that year; now the hospita
receives a definite proportion of each year's total, a
arrangement by which it is the loser. Dr. E. Rickards wa
warmly thanked for his valuable services, extending over
period of 30 years, and he was elected an honorary consultin
physician. The endowment of three beds during the year i
memory of deceased friends was remarked upon with satis
faction and gratitude and a hope was expressed that s
excellent a method of commemoration would find numerou
imitators. The report contained the interesting statemen
that only four hospitals in the whole of the United Kingdom
treated a larger number of out-patients annually. This wa
explained as due to the fact that the staff of the hospita
was frequently called upon to attend to trivial injuries an
to patients who could well afford to call in medical practi
tioners. At the Queen's Hospital a more satisfactor
condition of affairs obtained, for while the work i
both the in-patient and the out-patient departments ha
increased the subscriptions had also increased. On accoun
of the great pressure put upon the accommodation by th

large number of patients it was felt that some extension of the premises must be made and with that in view the committee of management has secured certain adjoining property The appointment of Mr Priestley Smith as honorary consulting ophthalmic surgeon was confirmed and warm testimony was borne to his valuable services during the long period he has been connected with the institution The Moseley Hall Convalescent Hospital at its annual [illegible] the amount of work and in [illegible] tter are still inadequate to [illegible] balance on the year being £259 At the meeting a desire was expressed that shelters in the grounds should be erected for tuberculous patients In each of the above annual reports it was suggested that the inhabitants of the neighbouring towns who benefited largely by the charities might subscribe more generously than they do at present

The Birmingham Hospital Saturday Fund

The executive committee of the Birmingham Hospital Saturday Fund was able to report at its annual meeting that a larger sum had been subscribed during the last year than ever before in the history of the fund, the sum raised was £18 643 There was a balance of over £1000 on the year s work. In addition to giving £10,000 yearly to the various Birmingham medical charities this excellent fund supports three convalescent homes at which no less than 2591 men, women and children have resided during the year To clear off a debt of £10,000 on one of the homes the committee has promoted an exhibition of the industrial arts of Birmingham by means of which it hopes to raise a substantial sum

The Adjourned Licensing Sessions

In a former letter it was stated that the members of the licensing committee had decided to "report ' 36 houses in Birmingham as possessed of licences which might with advantage to the city be removed At a later and final meeting this number has been reduced to 27, 16 of which are in the Floodgate street area where it is stated there is at present one licensed house to every 112 persons Of the nine licences which it was decided not to proceed against two have already been surrendered and the objections to the others were withdrawn In deciding which to "report attention was paid to the number in the neighbourhood and to the reputation and sanitary condition of the houses Whether all the 27 houses will have their licences removed or not depends now upon the amount of compensation to be paid and on the size of the fund

The Birmingham Board of Guardians

In order to remove pauper children from workhouse associations and also to relieve the pressure upon the accommodation the board of guardians has been recommended by a committee which has had the subject under consideration to purchase a site for the accommodation of those children particularly whose parents are known as ins and outs from the frequent periodic visits which they make to the workhouse In connexion with the projected labour colony for Birmingham a deputation from the Birmingham Aston and King s Norton unions is to pay a visit of inspection to the colony at Poplar

The Treatment of Sewage at Wednesbury

A new system of filtration has been instituted at the sewage farm belonging to Wednesbury The filter is made of coal has a superficial area of 500 square yards and is capable of dealing with 75 000 gallons per day According to Dr A Bostock Hill the percentage of purification effected is probably as high as at any works under similar conditions in the country It is stated that fish turned into the effluent are thriving in it

The Health Committee and ' Humanised Milk

Reverting to the proposed supply of "humanised milk in Birmingham the authorities although impressed by the advantage of the scheme carried out by the Liverpool corporation, are of opinion that it will involve too great an expenditure of public money They have been unable to come to any arrangement with the local milk vendors who consider that at the price at which the milk must be sold the profit would be insufficient The further consideration of the subject has been deferred

The Health of Birmingham

The death rate for the week ending March 4th was 16 2 and the zymotic death rate was 1 4, the increased mortality was due to whooping cough and pulmonary tuberculosis No fresh case of small pox was notified, there were four patients suffering from this disease in the hospital For the week ending March 11th the death rate was 16 8 and the zymotic death rate was 0 9 One fresh case of small pox was notified and removed to the hospital The number of patients in the scarlet fever wards showed an increase from 195 to 204

March 21st

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Dr A T H Waters's Jubilee of Membership of the Liverpool Medical Institution

AT the ordinary meeting of the Liverpool Medical Institution held on March 16th an address of congratulation to Dr A T H Waters on the attainment of his jubilee of membership of the society was moved by the President (Dr James Barr) seconded by Dr William Carter, and carried by acclamation The terms of the resolution were as follows —

> We the member [illegible] on wish to offer to Dr Alderman [illegible] ere congratulations on his attai [illegible] this institution of which he is [illegible] trust that he may be long spar [illegible] of a ripe and mature age We fully recognise the importance of his valuable contributions to medical literature which secured for him a wide reputation and shed lustre on the Northern Hospital, the Royal Infirmary and the Liverpool Medical School with which institutions his life-work had been closely associated Dr Waters has witnessed and shared in the great improvements which have taken place in medical practice during the past half century and he still shows the same keen interest as of yore in the advancement of the profession of which he is an honoured and a distinguished member He took an active part in the growth and development of the British Medical [illegible] honoured at [illegible] d general [illegible] ng spared

Extensions at the University of Liverpool Generosity of Mr F K Muspratt

At the last meeting of the Council of the University an offer was received from the president of the Council (Mr F K Muspratt) to provide for an extension of the chemical [illegible] cost, including equipment of [illegible] to say, was gratefully accepted [illegible] vote of thanks to Mr Muspratt was passed recognising the services rendered both by himself and by other members of his family in promoting the study of chemical science in Liverpool The following contributions for the extension and maintenance of the chemical department were also acknowledged by the Council —£100 a year for five years from the United Alkali Company, £100 from Mr George Wale of West Kirby, and £100 from Mr Thomas Threlfall of London

Country Hospital for Children at Heswall Gift of an Operating Theatre

About the middle of last year the committee announced that £30 000 had been collected of which £20,000 were for building and the balance was for a maintenance fund By a resolution passed in 1901 no building operations were to be commenced until £30 000 had been collected and it was expected that building operations would be commenced in the spring of 1905 It was intended at first to erect the central block which was estimated to cost £25 000 and which with slight alterations would accommodate from 60 to 70 beds [illegible] £20 000 will only partly provide for the central block [illegible] the necessary funds [illegible] t wards as it [illegible] plications and feels confident from the [illegible] the good results obtained from the small scale on which it is at present working at West Kirby that such a hospital is very urgently needed The committee hopes to receive building tenders in about six weeks The hospital will be unique in character and form Its shape will be that of the letter H the crosspiece representing the central block, consisting of dining rooms playgrounds &c while the wings will contain the wards When completed the building will be capable of containing 200 beds In response to an appeal made by Colonel Montgomery at the town hall last week, in his capacity as chairman of the Liverpool Country Hospital for Children, for a donation of £1000 in order to provide a clock tower for the new building about to be erected at Heswall, or for a similar sum to fit up and to complete an operating theatre, already a gratifying result has taken place. Mr. Holbrook Gaskell has intimated his intention of contributing £1000 towards the erection and complete furnishing of such a theatre. It is not too much to expect that a donation for the clock tower may soon follow.

Children's Convalescent Home, West Kirby.

The need of a nurses' home attached to this convalescent home is felt more and more and as the lease of the house at present rented for the nurses has not long to run the committee expressed the wish at the annual meeting of the supporters of the institution that an effort should shortly be made to raise £2000 for the erection of a permanent nurses' home on the grounds of the institution and connected with the main building. The number of children admitted to the home last year was 1191. The average number of cots occupied was 107. The total number of days spent by the children in the home during the year was 38,945. The year began with a debit balance of £182 and on Dec. 31st last the debt was £162. Subscriptions show a slight increase.

March 21st.

WALES AND WESTERN COUNTIES NOTES

(From our own Correspondents.)

Swansea Asylum.

When the Glamorgan asylum was established at Bridgend in 1864 it served the whole county, the population of which at that time was about 350,000. In 1901 the population numbered 860,000 and one result of this very considerable increase has been the decision of the county council to keep the Bridgend institution exclusively for patients from the administrative county. The Cardiff corporation is building a new lunatic asylum for Cardiff lunatics and the Swansea corporation has had notice to provide for those in Swansea. In connexion with the latter town it has been suggested that additions might be made to the recently erected Brecon and Radnor Asylum at Talgarth so that Swansea lunatics could be accommodated there. Talgarth is about 50 miles from Swansea and there is direct railway communication between the two places. The town clerk of Swansea has reported upon the proposal and he suggests that the 360 beds at Talgarth should be increased to 650, of which number the counties of Brecon and Radnor should be entitled to 350 and the county borough of Swansea to 300. The capital cost to Swansea of this scheme would be about £84,000, or some £40,000 more than Swansea is to receive from Glamorgan upon the dissolution of the partnership between the county borough and the county.

Bristol Hospitals.

The Bristol Royal Infirmary was established as long ago as 1735 and at the annual meeting of the board of management it was reported that the income received during 1904 exceeded that of the previous year by £750. There is still, however, an accumulated debt of £15,500. One very pleasing incident of the year was the receipt of a legacy of £142 from a former in-patient who, after devoting a small sum for the erection of a tombstone to her father and mother, made the trustees of the Royal Infirmary her residuary legatees.—The annual report of the Bristol General Hospital, which was established nearly 100 years after the infirmary, records an income for 1904 of £13,218 and an expenditure of £12,654. The number of in-patients treated was 2344, or 250 more than in the previous year.

Brentry Homes for Inebriates.

The management of the inebriates' homes at Brentry, near Bristol, has from time to time met with some adverse criticism. For several years there was a loss upon each year's working and in 1902 there was an accumulated debt of over £6000. The county and borough and district councils in the districts from which patients were sent to the homes contributed varying sums to extinguish the debt and the institution is now in a much more satisfactory condition. The report for 1904, which has just been issued, shows that the weekly cost per head of each inmate was only 13*s.* 8*d.*—a sum which compares favourably with that expended in similar institutions. The medical superintendent (Dr. David Fleck) gives an encouraging report of the work done during the year. He states that 41 of the 69 patients discharged from the homes during 1904 are doing well and appear to be cured completely.

Cardiff Infirmary.

Since the year 1862 successive mayors of Cardiff have each contributed 50 guineas to the funds of the Cardiff Infirmary but no contribution has hitherto been made directly from the corporation rates. As the result of an application from the secretary of the infirmary the corporation decided on March 13th to subscribe 200 guineas to the institution. A motion was proposed to make the grant an annual one but in the end it was decided to leave the corporation free each year to continue the contribution or not.

Visit of the Prince of Wales to Cardiff.

It is announced that the Prince and Princess of Wales will be the guests of Lord Windsor at St. Fagans at the end of June and that on June 28th the Prince, who is Chancellor of the University of Wales, will lay the foundation-stone of the new University College buildings in Cathays-park, Cardiff.

Health of Aberystwith.

In his recently issued annual report the medical officer of health of Aberystwith (Dr. A. Thomas) draws attention to the great scarcity of houses for working men in the town The water-supply is ample, the storage supply being equal to a ten months' supply, even reckoning a daily consumption of 25 gallons per head of the population. The birth-rate in 1904 was 24 per 1000 and the death-rate was 13·4 per 1000

The Queen Victoria Jubilee Convalescent Home, Bristol.

One of the last public ceremonies attended by the late Queen Victoria was in connexion with the opening of the convalescent home situated on the downs above Bristol. One of the principal reasons for the establishment of the home was to free the beds of the general hospitals in the city and during last year 504 patients were received from the Royal Infirmary and 482 from the General Hospital, while 577 patients came from elsewhere. The weekly cost per head was 14*s.* 9*d.*

The Devon County Council and the Treatment of Pulmonary Tuberculosis.

At the meeting of the Devon county council held on March 16th it was stated that the council did not at present propose to take any further steps towards the provision of a hospital for Devonshire for the treatment of pulmonary tuberculosis.

March 20th.

SCOTLAND.

(From our own Correspondents.)

Girgenti Inebriate Reformatory.

This reformatory, which is also known as "Girgenti Home," is under the control of the corporation of Glasgow and is situated at Irvine in Ayrshire. It is licensed for females only, and has accommodation for 58 inmates who are sentenced for three years under Section 24 (1) of the Inebriates Act of 1898 which authorises the detention of habitual drunkards who commit certain specified offences for the fourth time within a year. The report for the year ending Dec. 31st, 1904, shows that there were 39 inmates in the home at the beginning of that period and that there were 10 new admissions during the year. The first inmate was admitted to the home on Jan. 29th, 1901, and during 1904 the sentences of three years' detention expired in the case of 29 inmates who were accordingly discharged. Inquiries made as to the conduct of these women subsequently to their discharge led to them being classified as follows: doing well, nine; hopeful, six; doubtful, seven; and hopeless, seven. During the year four patients were transferred to the State reformatory at Perth on account of their refractory and pugnacious behaviour. The expenditure was equal on the average to £72 14*s.* 1*d.* per inmate per annum. The report by Dr. John Cunningham of Stewarton, medical officer of the home, refers at considerable length to a "special drug treatment" for inebriety but no information is given as to its nature.

Extension at the University of Aberdeen.

The building of the extension of Marischal College goes on apace. At a meeting of the University buildings committee on March 14th an important improvement of the plans of the masonry, which will have the effect of enhancing the appearance from the quadrangle of the architecture of the main gateway and the portion of the buildings in which the library is to be situated, was agreed to. The parapet over the gateway, instead of being plain as originally proposed, is now to be panelled and the flanking towers are to have 22 feet added to their height and are to be finished with granite domes to harmonise with those of the existing towers on the north and the south sides of the quadrangle. The pediment over the gateway is to be brought further forward than was originally intended in order to show better the rich moulding of the parapet, while the altering of the pitch of the pediment will also show the dome-capped towers to better advantage. The masonry of the front wall facing Broad-street has now reached the top of the fourth floor and there now remains only that of the fifth floor to be erected. It is expected that the whole of the masonry will be completed by the autumn.

Appointment of an Aberdeen Graduate.

Dr. Arthur Robertson Cushny has been appointed to the chair of pharmacology and materia medica at University College, London. Dr. Cushny is the fourth son of the late Rev. John Cushny of Speymouth and afterwards of Huntly and graduated with highest honours at Aberdeen in 1889, carrying off the Thomson travelling scholarship and the Murray medal, besides numerous other distinctions. After two years spent at the Universities of Berne and Strassburg, mainly in the study of pharmacology, he was offered and accepted the chair of materia medica and pharmacology at the University of Michigan. Of his work there the *Journal of the American Medical Association* says: "During his 12 years of residence in this country he has made many valuable original contributions to the science of his special subject. Some of his most important papers have been those bearing on the action of digitalis, caffein, &c. He has recently contributed to the English *Journal of Physiology* a series of researches on the physiology of, and the effect of medicinal agents on, the kidneys. He has made valuable contributions on the physiology of the mammalian heart and the interpretation of pulse tracings. His text-book on pharmaco[illegible] and has already passed [illegible] from this country [illegible] the most thorough scientific investigators in medical science." Dr. Cushny will enter on his new sphere of work in London in May.

March 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

Surgeon-General G. J. H. Evatt's report upon the position of dispensary medical officers is still a subject of dispute. The author has recently addressed a letter to the daily papers in justification of the attitude which he has taken and of the statements which he has made. He claims that his report should be published in full. The same opinion is expressed by some members of the Irish Medical Association, while others point out in the press that the report has never been adopted by the association and that it might well remain as a record of Surgeon-General Evatt's opinions on Irish medical affairs.

City of Dublin Hospital.

The annual meeting of the friends and supporters of the City of Dublin Hospital was held on March 14th. The Hon. Mr. Justice Barton occupied the chair and there was a large attendance which included Her Excellency the Countess of Dudley. Mr. Arthur Benson in seconding the adoption of the report said that although there was accommodation for 140 beds they were only able to maintain 100 owing to insufficient funds.

Royal Veterinary College.

His Excellency the Lord Lieutenant visited the Royal Veterinary College on March 16th and was received by the President, Sir Christopher Nixon, M.D. R.U.I.

Viceregal Visit to the Richmond Hospital.

His Excellency the Lord Lieutenant paid a visit to the Richmond Hospital on March 16th and was received by the board of governors and by the members of the medical staff.

The High Sheriff of Belfast.

As announced in THE LANCET of March 4th a medical man, Councillor Henry O'Neill, M.D. R.U.I., J.P., barrister-at-law, has become High Sheriff. His first duty as High Sheriff has been to try to bring the Belfast court-house into a decent sanitary condition. Early on the day in which the Belfast assizes opened he accompanied the sanitary staff of the city corporation over the whole place and had it thoroughly cleaned and disinfected.

Dispensary Medical Officers' Salaries.

The medical officers of the Coleraine union have asked the board of guardians to reconsider the scale of salaries proposed by them. This scale is for dispensary and workhouse medical officers—minimum salary, £90, increasing by £10 at the end of every five years' service until a maximum of £140 is reached. The Local Government Board has also advised the guardians to reconsider their proposal after further conference with the medical officers, as the scale proposed would not treat fairly medical officers who have large and populous districts and who have long periods of service. The guardians have decided to reconsider the matter on April 1st.

March 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Hepatico-gastrostomy.

AT the meeting of the Surgical Society held on March 8th M. Tuffier related the case of a woman, aged 39 years, on whom he had performed the operation of hepatico-gastrostomy on account of chronic jaundice. On opening the abdomen the gall-bladder was found to be distended by a colourless liquid and evidently did not communicate with the bile-duct. Between the hepatic duct and the common bile-duct there was a small tumour. M. Tuffier incised the hepatic duct and made an anastomosis between it and the anterior wall of the stomach. Eight days later a biliary fistula appeared and the patient left the hospital in an advanced state of cachexia.

Inoculation of Leprosy in the Monkey.

At the meeting of the Academy of Sciences held on Feb. 20th M. Charles Nicolle gave an account of some experiments on the inoculation of leprosy which he had carried out in monkeys. One was a Chinese bonnet monkey and the other was a macaque monkey. They were inoculated in the ear with fragments of tissue from a generalised case of tubercular leprosy. On the sixty-second day nodules appeared in both monkeys at the site of inoculation—namely, on the ear. Two weeks later one of these nodules was excised and was found to contain Hansen's bacilli. The bacilli-bearing cells were smaller than those which have been found in specimens excised from human beings but M. Nicolle attributes this to the lesions in the monkey having been at a very early age.

The Dangers of Overfeeding in Cases of Suspected Tuberculosis.

At a recent meeting of the Therapeutical Society M. Bardet read a paper on the above subject. He cited the case of a patient who on account of loss of weight and some pulmonary symptoms was considered to have tuberculosis and who was therefore sent to Montreux. Here he mended rapidly so that the local practitioner denied the existence of tuberculosis. Returning to Paris he continued his overfeeding and had no cough or at least only a "hysterical" (*quinteuse*) or nervous cough. Nevertheless he suffered extremely, being prone for many months to crises lasting for variable periods of time signalised by wandering pains which were most commonly felt in the neck, the jaw, or the upper part of the back. So severe were these pains that his medical advisers began to suspect the existence of tuberculous disease of the spine. The real explanation, however, turned out to be auto-intoxication from overfeeding in a patient affected by latent dyspepsia. This condition it was which gave rise to the cough and the neuralgia. Whenever he lost weight the cause was dyspepsia. M. Bardet therefore put him on a strict regimen. According to the patient's statements the total amount of his food could be estimated [illegible] mean of 5000 calories per diem [illegible] M. Bardet considered that he [illegible] calories and 60 grammes of [illegible] patient had gained three [illegible] kilogrammes in weight while the cough and the pains disappeared. M. Bardet argued that this case showed

ROYAL METEOROLOGICAL SOCIETY.—An interesting exhibition of meteorological instruments arranged by this society was held from March 14th to 17th in the library of the Institution of Civil Engineers, [illegible] street, Westminster. The chief feature was th[illegible] of recording instruments and also the methods adopted for ascertaining the meteorological conditions in the upper air. The instruments used by Mr. J. Glaisher, F.R.S., in his famous balloon ascents for the British Association for the Advancement of Science, 1862–66, were placed in position on the board as used in the car of the balloon. Mr. W. H. Dines exhibited the kites and meteorograph used by him at Crinan and Mr. W. S. Bruce showed the camera and meteorograph used with kites in the Scottish Antarctic expedition. The thermometers, anemometers, and sunshine recorders used on board the *Discovery* in the recent National Antarctic expedition were also exhibited as well as a number of beautiful water-colour drawings of sky and cloud effects in the Antarctic regions made by Dr. E. A. Wilson. Mr. J. L. Thomas exhibited a life-size "dummy" dressed in the remains of the clothes of a man who was struck by lightning near Cardiff on July 17th, 1903. M. Richard of Paris showed a collection of most of his self-recording instruments and Mr. Halliwell of Southport exhibited his new rain-gauges, anemometers, and evaporation tank. The Royal Meteorological Society arranged in a railed-off inclosure a typical climatological station. The Meteorological Council also showed in position the photographic barograph and the Beckley self-recording rain-gauge which were recently in use at the Fort William observatory. Many other instruments were shown as well as a large collection of photographs, records, drawings, maps, &c., illustrating meteorological phenomena.

AMBIDEXTERITY IN ART.—On March 16th, in the rooms of the Royal Statistical Society, Adelphi-terrace, London, W.C., Sir William Richmond, K.C.B., delivered a lecture on Ambidexterity in Art, being the second lecture in the series the delivery of which has been arranged by the Ambidextral Cultural Society. In his opening remarks the lecturer referred to an extraordinary feat performed by Sir Edwin Landseer who drew the profile of a stag's head with its antlers complete with one hand while with the other he outlined the profile of a horse. This, Sir William Richmond thought, clearly showed that Sir Edwin Landseer must have been able to use both sides of his brain separately and he admitted that he had tried to repeat the experiment and had failed. As evidence that ambidexterity was taught among the ancients he said that the Spartans were compelled to use the sword, the shield, and the spear equally well with either hand, while a modern instance of an ambidextrous nation is the Japanese. Ambidexterity, Sir William Richmond then pointed out, was of the greatest importance to a musician and especially to the organist who had also to use his feet in the execution of his art, so that probably nothing was more difficult to attain than the proper control of the limbs in organ playing. To the artist, and especially to the sculptor, ambidexterity was almost a necessity if he would excel in his art. Not only could one hand be rested while the other was working but in some cases the use of the left hand was required to produce the best work. To educate the left hand required perseverance and as an example of what could be done by perseverence he mentioned two cases. The first was that of a congenitally armless painter who copied the "Descent from the Cross," the colossal picture by Rubens, with his feet alone. The second was the case of a young man, paralysed in all his limbs, who learned to draw and even to engrave on copper using his lips, teeth, and tongue. A copy of a work of Albert Dürer, a seated figure known as the "Man of Sorrows," engraved in this astonishing manner, was handed round for inspection when those present who were acquainted with the original pronounced the copy to be a perfect replica. Sir William Richmond then referred to the ambidexterity of Leonardo da Vinci and showed to what a large extent in various handicrafts the Italians of the present day used their left hand, this being a survival of ancient custom, in which connexion he thought that it would be an interesting experiment to see whether an Italian child learned to become ambidextrous sooner than an English child receiving similar training. He concluded by expressing his belief that the work of the Ambidextral Cultural Society was of the greatest importance and thought that a deputation should wait upon the Board of Education to urge its views being [illegible]. The lecture was illustrated by drawings [illegible] of using the left hand without previous [illegible] much amusement being caused by the lecturer's [illegible] which was made with both hands simultaneously, and which portrayed a figure whose arms were differently posed. Thus the right hand of the sketch held a stick while the left, in a different position, held a cigar. This was a difficult feat, the difficulty, of course, lying in the fact that not only were the artist's two hands working simultaneously but they were working independently. The next lecture of the series will be given on April 12th, at 5 P.M., in the rooms of the Royal Statistical Society, by Mr. E. Noble Smith who will take for his subject "Ambidexterity in Surgery."

CENTRAL MIDWIVES BOARD.—The members of the Central Midwives Board met on March 16th at 6, Suffolk-street, Pall Mall, London, S.W., Dr. F. H. Champneys being in the chair. The first business on the agenda was the hearing of the charges alleged against Margaret Solley, a certified midwife, that on Jan. 29th, 1905, at the Cardiff police court, she was convicted of letting lodgings to seamen without being licensed in accordance with the by-laws of the corporation of Cardiff, her application for a licence for such purpose having been previously refused on the ground of her bad character. It was also alleged that she had harboured women of immoral character. The midwife in question attended the meeting of the Board and strenuously protested against the charges. The Board decided that her name should be removed from the roll of midwives. The Board next heard the charge alleged against H. E. Clementson, a certified midwife, that on Oct. 22nd, 1904, while in attendance on a woman in labour she was drunk and thereby incapable of performing her duties as a midwife. This midwife sent a letter to the Board protesting her innocence. The Board decided that her name should be removed from the roll. The Board then considered the applications of candidates for the inspectorship and Dr. Lucy Beatrice Clapham was elected.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—The members and friends of the Irish Medical Schools' and Graduates' Association [illegible] dinner on March 18th, in the Grand [illegible] Strand, London, W.C., the President of the association, Sir William Whitla, being in the chair. The loyal toasts having been duly honoured, Dr. J. H. Swanton, chairman of the council of the association, introduced Captain Thomas Campbell Mackenzie, D.S.O., R.A.M.C., to the President who asked Lady Whitla to present to Captain Mackenzie the Arnott memorial medal. The medal was granted to Captain Mackenzie for saving life at sea. On his way home from Mauritius during the passage through the Ionian Sea on Sept. 22nd, 1904, one of the crew fell overboard and though the sea was running high and a strong wind was blowing Captain Mackenzie dived fully dressed over the ship's side and securing two lifebelts which were thrown to him lashed the drowning sailor to one, retained the other himself, and waited rescue. The order was given to stop the vessel but owing to the rough sea and the speed of the boat the two men in the water were soon lost to sight and it was 40 minutes before they were found and taken on board in a very exhausted condition. The Director-General of the Army Medical Service wrote stating that Captain Mackenzie was already distinguished for his gallantry and devotion to duty with the Irish Brigade in South Africa and was a credit to his country and to the Irish medical schools. Captain Mackenzie modestly acknowledged the honour in a few brief words, declaring that it was only just his luck that he was present when the accident occurred and that any other man would have done just the same. The toast of "Our Defenders" was intrusted to Mr. J. Gubbins Fitzgerald and was acknowledged by Inspector-General W. H. Lloyd, R.N., Director-General A. H. Keogh, and Colonel Leese. The President of the Royal College of Surgeons in Ireland (Mr. A. Chance) proposed the toast of "Our Guests" and deplored the fact that certain medical schools in London required holders of Irish degrees to take further degrees before they stood a chance of election on the medical staffs. Mr. T. Lough, M.P., in acknowledging t[illegible] terms to the condition [illegible] officers. Mr. J. Tweedy, [illegible] Surgeons of England, at very short notice gave the toast of "The Association" and described how successful it had been.

The President duly acknowledged this toast on behalf of the association and the proceedings terminated.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Hasenfeld, *privat-docent* of balneology in the University of Budapest.—Dr. Johann Hjort, an eminent Norwegian ophthalmic surgeon.

LITERARY INTELLIGENCE. — The Walter Scott Publishing Company, Limited, announce the publication of a work, "Science and Hypothesis," by M. Poincaré, the well-known French mathematician and *savant*. The work is prefaced with an introduction from the pen of Joseph Larmor, M.A., D.Sc., secretary of the Royal Society. —Tourists about to visit Sicily will find a variety of information on local subjects in *La Sicile Illustrée*, a monthly journal of about 32 pages published by S. Marraffa Abate and Co. of Palermo. The languages used in the paper are principally Italian and French with a smaller proportion of English and German. It is the official journal of the Association Sicilienne pour l'Avantage Économique.—Messrs. J. and A. Churchill are about to publish a work by Dr. James Taylor, entitled "Paralysis and other Diseases of the Nervous System in Childhood and Early Life." A feature of this book will be the numerous reproductions of [illegible] lucidating the text. Another [illegible] es of Children," by Dr. J. F. [illegible] will be issued by the same [illegible]

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The annual meeting of the governors of this institution was held on March 21st, among the governors present being the Duchess of Albany. Mr. J. Danvers Power, who presided, in moving the adoption of the report, said that every possible recommendation of the committee appointed in 1901 had been complied with, while economies making a total of £2800 had been effected during the year. The hospital was now well worked in every way, the requirements of the medical staff had been satisfied in every way, and the nursing staff had been [illegible] being undertaken by the [illegible] tion which would be of gr [illegible] hospital was bankrupt. Great reductions had been made in expenses, without any sacrifice of efficiency, for the cost per bed, which had been £94 in 1903, was now only £81, but those responsible for its management required at least another £5000 per annum to carry on their work properly. At the conclusion of the meeting the Duchess of Albany expressed a hope that, since the condition of the hospital had been brought before the public, both as to its improved efficiency and its needs, the public would rightly appreciate and realise the importance of the same.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Training and Registration of Nurses.

Mr. CLAUDE HAY has introduced a Bill to provide for the better training and registration of nurses and for the voluntary registration of private nursing homes. The proposals are "backed" by Sir ARTHUR BIGNOLD and Mr. H. D. GREENE.

The Proposed Abolition of Compulsory Vaccination.

A Bill for the abolition of compulsory vaccination has made its appearance this week. Its sponsor is Mr. BROADHURST who is receiving the support of Mr. THOMAS BAYLEY, Sir JOHN ROLLESTON, Mr. CHANNING, Mr. CORRIE GRANT, and Mr. LEVY.

Dogs and Vivisection.

Following upon the series of questions on vivisection that have been put in the Commons since the session commenced Mr. ELLIS GRIFFITH has promoted a Bill for the prohibition of experiments upon dogs. Among those who are interesting themselves in the matter are Colonel LOCKWOOD, Colonel SANDYS, Mr. CHANNING, Mr. FIELD, Mr. TOMKINSON, and Mr. WEIR.

The Physical Condition of School Children.

The terms of reference to the inter-departmental committee on this subject which the President of the Board of Education has appointed in [illegible] ament Board are [illegible] being done and [illegible] ildren in public elementary schools; (2) and further, to inquire into the methods employed, the sums expended, and the relief given by various voluntary agencies for the provision of meals for children at public elementary schools, and to report whether relief of this character could be better organised without any charge upon public funds both generally and with special regard to children who, though not defective, are from malnutrition below the normal standard.

The London County Council General Powers Bill.

When this Bill came before the Commons on March 16th two instructions to the committee which will have to consider the Bill in detail were carried. The first was adopted by a majority of six and it was that the committee should omit the clause which would enable the Council from time to time to make representations to the Local Government Board as to the manner in which the Sale of Food and Drugs Acts, 1875 to 1899, are administered within the county. The second was to the effect that the committee should substitute in Part 4 of the Bill the medical officer of a borough council for the medical officer of the County Council. It was urged by Mr. CLAUDE HAY that matters connected with milk-supply and the dangers arising from milk-borne disease were much more likely to be effectively dealt with by the medical officer of the district than by the medical officer of the County Council. The instruction was agreed to by a majority of 14.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 15TH.

The Higher Education of Nurses

[illegible] hether the [illegible] ence to the [illegible] the select [illegible] nto the registration of [illegible] l: The Board of Trade [illegible] the objectors to, the [illegible] the Higher Education [illegible] ropose to come to any [illegible]

The Number of Commissioners in Lunacy.

[illegible]

Vaccination Exemption Certificates.

Mr. WEIR asked the President of the Local Government Board [illegible] certificates received during that year may be stated approximately as 39,750. The numbers in 1902 and 1903, respectively, were 33,632 and 37,259.

The Consumption of Methylated Spirit.

Mr. JOSEPH DEVLIN asked the Chief Secretary for Ireland whether his attention had been called to the mischief wrought amongst the working class in Derry city and county by the consumption of methylated spirit, and whether, in view of the consequences proceeding therefrom, he would take steps to have restrictions placed on the sale of this article and to warn the people of the dangers arising from its use.—Mr. LONG replied: The attention of the Board of Inland Revenue has been directed to the practice of drinking methylated spirit in Londonderry. It is an offence under the Spirits Act, 1880, to sell such spirit as a beverage. The officers of the Inland Revenue are using their best endeavours to procure evidence which will sustain proceedings under the Act in this respect and the police have been instructed to afford them every assistance in the matter.

THURSDAY, MARCH 16TH.

The Feeding of School Children.

Mr. JAMES HOPE asked the Secretary to the Board of Education whether he hoped during the present session to introduce legislation [illegible] the feeding of children in public elementary schools — [illegible] ot intended to introduce any such [illegible]

The Dismissal of Medical Officers in Scotland.

Mr. CATHCART WASON asked the Lord Advocate whether his attention had been directed to the numbers of cases of dismissal of medical [illegible] thereby by the poor and [illegible] of the Local Government [illegible] e fact that the Medical Association had [illegible] applicants against accepting appointments in certain parishes; and whether, in all the circum- [illegible] The honourable Member has himself introduced a Bill on the [illegible] session. subject and, as he is aware, the question is a very controversial one.

Vivisection in Glasgow.

Mr. WEIR asked the Home Secretary whether he would state how many animals were inoculated with the rabies virus in the performance of the two experiments carried out by Mr. R. M. Buchanan at the Veterinary College, Glasgow, under the Cruelty to Animals Act, 1876, referred to in the government inspector's report for 1903; and the number of animals used for the purpose of vivisection under the above Act for the years 1903 and 1904.—Mr. Akers-Douglas replied: In the two experiments in question two rabbits were inoculated, not with rabies virus, but with emulsion of the brain of a dog which had been killed by the police on suspicion that it was rabid. The experiments were carried out at the Glasgow Public Health Laboratory, not at the Veterinary College. In answer to the second part of the question I have to say that the returns for 1904 are not yet complete. In 1903 the number of experiments performed was 19,084, of which nearly 17,000 were inoculation or feeding experiments. The number of animals used for the purpose of these experiments cannot be precisely stated but it is slightly less than the total number of experiments.

Cats and Dogs for Vivisection.

Sir Frederick Banbury asked the Home Secretary whether he was now in a position to make a further statement as to the purchase of cats and dogs from persons convicted of stealing these animals for the purposes of vivisection.—Mr. Akers-Douglas answered: I fear I cannot add anything to the answers on this subject which I gave on the 23rd of last month. I have no information showing that cats and dogs are purchased for the purposes of experiment from persons who have been convicted of stealing those animals.

The Report on Physical Deterioration.

Sir John Gorst asked the First Lord of the Treasury whether the Government would refer the report of the Departmental Committee on Physical Deterioration to a Select Committee of the House of Commons.—Mr. Balfour said: In answer to my honourable friend I have to say that so far as the report to which he refers relates to public elementary schools a departmental committee has been appointed to obtain precise information as to the extent of the evils complained of, and I think in the meantime the course which he suggests would not be desirable. I should like to reserve judgment on that until the departmental committee has reported.

Mosquito-Proof Sleeping Rooms.

Mr. Cathcart Wason asked the Secretary of State for the Colonies whether in view of the established relations between malaria and mosquitoes he would cause inquiry to be made as to the expediency of erecting mosquito-proof sleeping rooms for the employés on our West African railways.—Mr. Lyttelton said: The quarters provided for railway employés in Sierra Leone and Lagos include mosquito-proof rooms. As regards the Gold Coast I have no information but I will make inquiry. I may add that mosquito nets have also been supplied by the Government but I understand that some change has recently been made in Lagos and I will inquire about it.

MONDAY, MARCH 20TH.

The Physical Condition of School Children.

Sir John Gorst asked the Secretary to the Board of Education whether on the occasion of his visit to the Johanna-street Board School he found any children unfit to attend to the duties of the school in a proper way; whether he had any reason to think that Dr. A. Eichholz in his evidence before the Commission on Physical Deterioration exaggerated the proportion of such children; and whether public money was still spent at this school in providing instruction which the children could not from their physical condition attend to.—Sir William Anson replied: On the occasion of my visit to the Johanna-street Council School the children were attending to the duties of the school in a proper way, but I think that many of them might with advantage have been provided with a curriculum more suited to their capacities. I am not in a position to criticise the medical evidence of Dr. Eichholz but I have good reasons for thinking that it may not be final. The school is still being conducted as a public elementary school.

Sir John Gorst asked the Secretary to the Board of Education whether he would give the names of the departmental committee which the President of the Board of Education had appointed for the purpose of providing useful and precise information on the physical condition of children in public elementary schools and the date of their appointment; what methods the committee had adopted for obtaining information more precise than that furnished to the Committee on Physical Deterioration by Dr. Eichholz and other witnesses; and to what use the information thus provided had been put.—Sir William Anson said: An inter-departmental committee, consisting of Mr. H. W. Simpkinson, C.B., assistant secretary of the Board of Education, chairman; Dr. H. Franklin Parsons, assistant medical officer under the Local Government Board; Mr. C. Jackson, chief inspector of elementary schools under the Board of Education; the Honourable Maude Lawrence, chief woman inspector of the Board of Education; Mr. R. Walrond, senior examiner of the Board of Education; with Mr. E. H. Pelham, junior examiner of the Board of Education, as secretary, was appointed on March 9th to collect certain information as to the medical inspection of children in elementary schools and as to the provision of meals for such children by voluntary agencies. I am sending the right honourable Member the terms of reference. I am not prepared to state the methods which the committee will employ for obtaining this information. But I hope that it will provide information more thorough and precise than any which we at present possess and will enable deductions to be drawn less indefinite in character than those which are supplied in the report of the Committee on Physical Deterioration.

Sir Walter Foster asked the President of the Local Government Board whether, in view of the evidence given before the Committee on Physical Deterioration relating to the condition of children, he would issue a circular to boards of guardians calling their attention to their powers and duties as to underfed childr[illegible] importance, in the case of giving out-relief to [illegible] milk rather than a large amount of bread.—[illegible] said: So far as I am aware there is no reason to suppose that boards of guardians are not alive to the powers and duties which attach to them in relation to underfed children, where application is made to them for relief. With regard to the latter part of the question I think that boards of guardians may be trusted to use their discretion as to giving milk as out-relief to young children. The Local Government Board called the attention of its inspectors to the subject last year. It does not appear to me to be necessary to issue a circular as suggested.

Underground Bakehouses.

Mr. Field asked the President of the Local Government Board whether his attention had been drawn to the report of a case in which the mayor, aldermen, and council of the borough of Paddington were summoned for refusing to grant a certificate to allow a baker to use his premises; and whether having regard to the observations made by the stipendiary magistrate who dealt with the case (granting at once the necessary certificate) he would in the interests of traders issue a circular to all borough councils and administrative bodies as to their duties under the Acts relating to public health and sanitation.—Mr. Gerald Balfour replied: I [illegible] f the case referred to and have made s[illegible] I understand that the consideratior[illegible] borough council and its officers have administered the enactment under which the proceedings were taken has been acknowledged by a considerable number of the proprietors and lessees of underground bakehouses in the borough, and it does not seem to me necessary to issue any such circular as that suggested.

Combating Plague in India.

Sir Walter Foster asked the Secretary of State for India whether his attention had been drawn to the successful action taken by the Madras municipal authorities in repressing a recent outbreak of plague in the fishing village of Kuppam; whether he was aware that the measures by which plague had been kept out of the city of Madras had met with popular approval; and whether he would invite the Government in other provinces to follow the example of Madras and to take measures for the prevention of plague in consultation with the municipal and rural local authorities.—Mr. Brodrick answered: I have seen accounts of the case which reflects great credit on the local health officers. The hamlet, however, was very favourably situated for the early discovery of the outbreak and for prompt and effective action to stop its spread. All provinces in India have rules which prescribe that similar preventive measures shall be taken by Government officers in consultation with the municipal and rural authorities and with the concurrence of the people. But the degree of success must necessarily depend on local circumstances.

Medical Officers of Health and Practice.

Mr. Weir asked the Lord Advocate how many county medical officer of health in Scotland now engage in general or consultative practice.—The Lord Advocate replied: I am informed by the Local Government Board that the number is six.

TUESDAY, MARCH 21ST.

Limited Liability Companies and Poison Regulations.

Mr. Remnant asked the Home Secretary whether, in view of the fact that limited liability companies were not amenable to the poison regulations prescribed by the Pharmacy Act, 1868, and approved by the Privy Council, and to the statement of the President of the Board of Trade that the question of amending the law to remedy this evil would not be germane to a Companies Bill, he would take into consideration the expediency of recommending that facilities should be given during the present session for the passing of the Pharmacy Acts Amendment Bill, which was designed to place companies in the same position as individuals in regard to the sale of poisons.—Mr. Akers-Douglas replied: I regret that I cannot promise facilities to the Bill referred to by the honourable Member. I am not in a position to add anything to the answer which I gave the other day to Sir John Tuke.

Pauper Alien Lunatics and Imbeciles.

Colonel Legge asked the Home Secretary whether he could give the number of pauper alien lunatics and imbeciles maintained in lunatic asylums and public institutions in the United Kingdom, and whether any means existed of ascertaining the country of origin of such lunatics and imbeciles.—Mr. Akers-Douglas said: The number of pauper alien lunatics maintained in county and borough asylums in England and Wales was in 1903 817, as is shown in Table XIVA on page 146 of the last report of the Commissioners in Lunacy. The same table gives the countries of origin, information as to which is obtained from the medical officers of asylums. I regret that I am unable to give the number of alien imbeciles maintained in public institutions other than asylums and also that, without longer notice, I cannot give the number of alien lunatics for the whole of the United Kingdom.

Vaccination Exemption.

Mr. Weir asked the Home Secretary whether he was aware that a labourer named Harrison was recently refused a certificate of exemption from vaccination for his child by the magistrates sitting at Spilsby and Boston; that he was subsequently summoned and in default of payment of the fine of £1 and £1 2s. 6d. costs was sent to prison for one month; and that since this man's release he was on Feb. 27th again summoned for not obeying the vaccination order; and, in view of the fact that he had repeatedly endeavoured to make clear that he conscientiously believed that vaccination would be prejudicial to the health of his child, would the Home Secretary consider the expediency of directing the attention of the magistrates at Spilsby and Boston to the remarks made by the Lord Chief Justice at Birmingham on July 27th last in regard to the principles on which the Act ought to be administered.—Mr. Akers-Douglas answered: I have made inquiries into this case and I learn that the remarks on the subject of conscientious objection to vaccination made by the Lord Chief Justice at the Birmingham summer assizes were brought to the notice of the Spilsby magistrates before they convicted Harrison. The question whether the circumstances justify the issue of a certificate of exemption is in each case one for the discretion of the magistrates, with which I have no power to interfere.

Notes, Short Comments, and Answers to Correspondents.

A QUESTION OF FEES.

To the Editors of THE LANCET.

SIRS,—Would you kindly help me with your opinion in the following case? A lady, a patient of mine, has a distant cousin who has to earn her living as a companion with a salary varying from £15 to £20 a year. While staying with her employer at a small country village this cousin is attacked with hæmoptysis and is for some weeks seriously ill. The resident doctor, living quite near, is called in and he advises and supplies medicine for about three months; in all 96 visits are paid, but some of these are at the rate of two and three per day. There is no doubt that the doctor is most kind and attentive, but some of the visits charged, especially in the case of second and third visits, were merely visits of inquiry at the end of the day's round. During the course of the illness my patient pays a visit to her cousin and casually meeting the doctor says, "I hope that you will do what you can for Miss ——." In due course an account is sent to Miss ——, amounting to £32, a sum entirely beyond her power to pay. By degrees her friends, including my patient, help her to pay £12. She is then pressed by the doctor to pay the full sum and he also threatens my patient with the county court. She puts the matter in the hands of her lawyer who advises her that she has no legal liability, informs the doctor that he is ready to accept service of a summons, and hears no more of it.

My patient is not desirous of taking refuge behind a legal technicality from a just claim and is willing to pay a reasonable sum to settle the account. She is, therefore, anxious to ascertain what would be a fair charge in the circumstances. I have advised that 3*s.* 6*d.* a visit to include medicine would be a reasonable sum. The detailed account shows 96 visits charged—this would be £16 16*s.*; £1 1*s.* was paid as a consultation fee and 30*s.* were paid for ice and brandy, making a total of £19 7*s.* Of this £12 has been paid and my patient is ready to pay a further sum of seven guineas to settle the account on behalf of her cousin. Would this be fair?

I am, Sirs, yours faithfully,

March 20th, 1905. A CONSULTANT.

*** We should say from the circumstances detailed above that 3*s.* 6*d.* per visit is a reasonable sum to offer.—ED. L.

THE "SAFETITE" DOOR CATCH.

THIS is an ingenious device for securely fastening an ordinary room door or house door in such a way that it may remain open to the extent of a few inches. On shipboard, especially in vessels which enter warm latitudes, the doors of the officers' and passengers' rooms are usually provided with hooks for this purpose but these are no protection against intruders as they can obviously be unhooked from either side of the door. The "safetite" door catch, on the contrary, is fixed inside the door and can only be applied or unfastened by the occupants of the room. A door may therefore by this means be kept partly open for the purpose of admitting fresh air without the possibility of anyone entering from the outside. This catch works on nearly the same principle as the chain of a front door. A knob, supported by a narrow neck, slides on a short metal rod hinged to the door-post, while at a corresponding level on the door itself there is a tube open at one end and having a longitudinal slot. The knob is made to enter the end of the tube and as the door is gradually opened the neck of the knob slides in the slot until the end of the latter is reached and further progress thereby stopped. The catch is made in three qualities, costing respectively 2*s.* 8*d.*, 3*s.*, and 3*s.* 6*d.* each. It may be obtained at 12, Irwell-chambers West, Union-street, Liverpool.

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to acknowledge the receipt of the following additional contributions? Mr. N. E. Thomas, £1 1*s.*; Dr. S H. Steel, 5*s.*; Mr. Fred. Buckham, 5*s.*; previously acknowledged, £69 18*s.* I am, Sirs, yours faithfully,

ALEX. P. FIDDIAN, M.B. Lond.,
23, The Walk, Cardiff, March 21st, 1905. Honorary Treasurer.

◆

C. A. M.—We do not know of any text-book of "pathology" in which such conditions as "coma" and "delirium" are described. In the larger treatises on medicine, such as Professor Clifford Allbutt's "System," the pathology of delirium and coma will be found to be discussed under the various diseases in which they occur.

K. C.—We sympathise with our correspondent's views in general, but having regard to the particular journal in which the announcement appeared and to the name of the invalid we think that in this instance the offence does not lie with the medical men.

R. C.—We think that Dr. X ought to have made some communication to Dr. A, but perhaps he was assured that this had been done by the patient's family.

Inquirer.—We propose to publish a note on the method.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Wee

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P. Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M. [illegible] (Gt. Ormond-street, W.C.).— P.M. Lecture:—Mr. Collier: Some Diseases of the Urinary Organs.

DAY (31st).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.). 5 P.M. Dr. Abraham: Cases of Skin Disease.

DICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. S Stephenson: Clinique. (Eye.)

RTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4 30 P.M. Lecture-Demonstration:—Mr. A. de Prenderville: Anæsthetics.

EDITORIAL NOTICES.

It is most important that communications relating to the [illegible] torial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any [illegible] ntleman who may be supposed to be connected with the [illegible] torial staff. It is urgently necessary that attention be [illegible] n to this notice.

[illegible] especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

[illegible] cannot prescribe or recommend practitioners.

[illegible] l papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

[illegible] ers relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

[illegible] cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with [illegible] issue of Dec. 31st, and the Title-page to the Volume, [illegible] e given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are [illegible]

THE [illegible]

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.
